[2] Since this communication was made we have found a description of the pear sand by Dr Alexander Marcet, in his "Essay on Calculous Disorders" (p 132), published in 1817. The description was based upon specimens the true nature of which had been recognised by Wollaston.

growth in 48 hours at 37° C. In Analysis 1 the broth used had been inoculated with one cubic centimetre of Flask VII., equivalent to 0·000,000,02 gramme of fæces, and in Analysis 3 with one cubic centimetre of Flask VI., equivalent to 0·000,000,2 gramme of fæces. In both instances the guinea-pig died in a few days from septicæmia and a bacillus corresponding in morphological and cultural respects with the bacillus coli communis was recovered from its heart's blood. The fact that the virulent bacillus coli was the most abundant organism that developed in broth in both instances, and also the fact that after taking 42 minims of izal oil by the mouth the abundance of this pathogenic microbe was diminished by presumably 90 per cent., are points that go far to explain the clinical success of izal in the treatment of diarrhœa and dysentery.

*Experiment II.*

| Conditions. | | Analysis 4. —Normal. | Analysis 5. —After 50 minims of izal oil. | Analysis 6. —After 78 minims of izal oil. | Analysis 7. —32 hours after stopping izal oil. |
|---|---|---|---|---|---|
| Since experiment began | Time... | — | 48 hours. | Sixth day. | Eighth day. |
| | Motion | — | Second. | Sixth. | Ninth. |
| Total number of micro-organisms in agar at 37° C. | | 200,000,000 | 260,000,000 | 20,000,000 | 60,000,000 |
| Total number of micro-organisms in gelatin at 22°C. | | 220,000,000 | Approximately 200,000,000 | 20,000,000 | 40,000,000 |

The reduction after taking 78 minims of izal oil was therefore in the case of the organisms developing at blood-heat 90 per cent, and in the case of those growing at 22° C. 91 per cent. On the other hand, 32 hours after stopping the drug, the increase was in the case of the former 300 per cent. and in that of the latter 200 per cent.

*Experiment III.*

| Conditions. | | Analysis 1.— Normal. | Analysis 2 —After 36 minims of izal oil. |
|---|---|---|---|
| Since experiment began. | Time ... | — | Fourth day. |
| | Motion... | — | Fourth. |
| Total number of micro-organisms in agar at 37° C. ... .. .. . ... | | 20,000,000 | 8,000,000 |
| Total number of micro-organisms in gelatin at 22° C. . .. . .. | | 10,000,000 | 6,000,000 |
| Total growth in broth at 37° C. .. .. ... . | | 200,000,000 under 2,000,000,000 | 20,000 000 under 200,000,000 |
| Total indol in broth at 37° C. | | 2,000,000, under 20,000,000 | 200,000 under 2,000,000 |

The reduction after taking 36 minims of izal oil was therefore in the case of the organisms developing at blood-heat 60 per cent. and in the case of those growing at 22° C. 40 per cent The total growth in broth, as also the production of indol, were both reduced by 90 per cent.

The total numbers in agar and in gelatin were in both analyses in Experiment III. estimated from plates inoculated with one cubic centimetre of the fourth dilution—that is to say with an amount representing 0 000,02 gramme of fæces. In the two preceding experiments, on the other hand, the dilution used for this purpose was a much higher one—e g., one cubic centimetre of the sixth or seventh dilutions representing 0 000,000.2 or 0 000,000,02 gramme of fæces respectively. The latter is far more accurate as a gauge of the actual total of the organisms present in the material itself, for, in plates made from the lower dilutions, owing to a larger number of organisms being present, overcrowding occurs and a proportion of them are unable to grow into colonies and so escape being counted. The two analyses, however, in Experiment III. are strictly parallel, the same amount of fæces having been cultivated in each case, so that the numbers are strictly comparable though not necessarily, or, indeed, probably, a gauge of the actual total present in the material itself. The growth in broth is a better index in this sense as a matter of fact.

SUMMARY AND CONCLUSIONS.

The total number of micro-organisms present in a gramme of fæces and developing in agar-plates at blood-heat was reduced in Experiment I. by 86 per cent., in Experiment II. by 90 per cent., and in Experiment III. by 60 per cent. Moreover, the pathogenicity of the fæces was reduced in Experiment I. by presumably 90 per cent. The only condition introduced that accounts for this effect was that izal oil was being taken by the mouth and the diminution of the micro-organisms in the fæces was broadly proportionate to the dose of the drug. Thus in Experiment I. after 20 minims of izal oil the reduction of the blood-heat organisms was 68 per cent., and only after 42 minims did the reduction reach 86 per cent. Again, in Experiment II. after 50 minims of the oil no reduction, but an actual increase, of the blood-heat organisms was noted. But this was only the second motion since the experiment began, and later, after 78 minims of the oil had been taken, their reduction was as much as 90 per cent. On the other hand, in the same experiment 32 hours after izal had been stopped the organisms developing in agar plates at blood-heat were increased by 300 per cent.

I believe that these results justify the inference that not only does the ingestion of izal oil in doses that give rise to no untoward symptoms diminish the number of micro-organisms in the fæces, but that it does so to a very striking extent.

The fact that in spite of the great reduction effected the number of micro-organisms remaining in the fæces was still large is at first sight disappointing. It is, however, no reason for withholding the drug in cases where it is indicated. In the first place the diminution effected may make a great deal of difference to the progress of a given case. Again, for aught we at present know to the contrary, the health of the intestine may be dependent on a state of equilibrium of its bacteriological contents, and a slight disturbance of this equilibrium may be a condition resulting in serious illness. The indication in such a condition would be to restore the disturbed equilibrium, and a drug that can be depended on to achieve this result with certainty and without injury, pain, or even inconvenience, is not to be lightly valued. Thirdly, it is probable that by pushing the dose of izal, but still keeping outside the limit of its toxicity, the number of fæcal organisms may be still further reduced Again, by combination of izal with other drugs and by careful dietetic treatment it may be possible to reduce still further the pathogenicity and foulness of the intestinal contents.

As in the case of other remedies, however, the scope of izal as an intestinal antiseptic is a matter that can only be eventually established at the bar of clinical experience. Possibly other drugs may be still more efficacious for the purpose stated. But my observations so far with salol and with *β* naphthol *in vitro* have not led me to form the opinion that they are likely to be among them. This opinion, however, is advanced with all reserve, as I have not yet tested these drugs *in vivo* in the same way as izal.

The success of izal as a remedy for diarrhœa and for dysentery is, according to the authorities cited, a clinical fact. Whether by means of this or another intestinal germicide it will ever be possible to control typhoid fever, appendicitis, &c., at the site of infection is a matter for the future to determine.

In conclusion, I wish to record my thanks to Dr. Houston for much valuable advice.

# TWO CASES OF LUPUS VULGARIS SUCCESSFULLY TREATED WITH UREA PURA AND THE X RAYS.

BY EDWARD SWALES, M.R.C.S. ENG., L.R.C.P. LOND.,
THIRD ASSISTANT MEDICAL OFFICER, KENT COUNTY ASYLUM, MAIDSTONE.

A GREAT deal of interest has been centred , lupus vulgaris of late, owing to the introduction of new methods of treatment. Much has been written of the value of the Roentgen rays in this disease, and many successful cases have been recorded. The Finsen light treatment is being extensively employed and great things are expected from it.

surgical disinfectant and with excellent results. The credit, however, of introducing izal as a disinfectant in the medical sense belongs to Dr. F. W. Tunnicliffe.[4] In his exhaustive report on the pharmacology of izal he remarks that "animals, even after large doses, retain a good appetite and do not suffer from diarrhœa or vomiting. The fæces smell of izal, showing that it is capable of exerting its antiseptic influence throughout the alimentary tract." He also found that "it gives evidence of its presence in the breath." On these grounds, no less than because it combined a low toxicity (0 5 to 1·5 cubic centimetres of the 40 per cent. emulsion pro kilogramme) with high germicidal properties, he recommended its therapeutic trial as a pulmonary or as an intestinal antiseptic.

The event has justified the recommendation. In a recent article in THE LANCET[5] Dr. Tunnicliffe has described some gratifying results obtained by him in a series of cases of phthisis treated with izal As an intestinal antiseptic, also, the therapeutic employment of izal has so far been attended with considerable success. In a note on the treatment of dysentery during the South African campaign Dr. W. Watkins-Pitchford[6] speaks highly of its efficacy combined with bismuth and chlorodyne The trial of izal was made at the suggestion of Dr. G. W. K Crosland. It is stated that "in the few sporadic cases of dysentery which have arisen in our hospital this combination of drugs has in every case brought about a rapid cure, and in those well-advanced cases of a severe type which have come under our care the results of its use have been equally gratifying." Dr. Tunnicliffe has also found izal to be remarkably efficacious in controlling intestinal putrefaction Under its influence the diarrhœa in several cases of infantile summer diarrhœa ceased, and in another case obstinate phthisical diarrhœa was similarly arrested.

A short time since, when making a comparative investigation of the relative germicidal value of various antiseptics *in vitro*, I was much impressed by the results obtained with izal, and especially with the "medical izal" and with the pure izal oil. I proceeded, therefore, to inquire whether the germicidal action of izal could be proved to take place *in vivo*, and, if so, whether it could be measured. The question to be determined was briefly this: Is the number of micro-organisms in the fæces diminished by taking izal by the mouth, and, if so, to what extent? The method adopted for the quantitative investigation of fæcal micro-organisms was as follows. Eight small flasks were plugged with cotton-wool and sterilised. The first flask contained 100 cubic centimetres of sterile distilled water and each of the other seven contained 90 cubic centimetres of the same. Fæces (free from urine) were collected in a sterile vessel and half a gramme was weighed out carefully in a sterile watch glass The watch-glass was then placed in a sterile beaker and the contents of Flask I.—i.e., 100 cubic centimetres of sterile distilled water—were poured over it and thorough mixture was effected by stirring with a glass rod and constantly shaking for about half an hour. The mixture was then transferred to Flask I., which thus contained 0 5 gramme of fæces in 100 cubic centimetres of water, a dilution of 1 in 200. 10 cubic centimetres of Flask I. were next transferred to Flask II. and thoroughly mixed. The dilution made in Flask II. was thus 1 in 2000 With a fresh sterile pipette 10 cubic centimetres of Flask II. were transferred to Flask III and so on up to Flask VIII. Now one cubic centimetre of Flask I. contains 0 02 gramme of fæces and one cubic centimetre of each of the succeeding flasks represents one-tenth less, or respectively 0 002, 0 000,2, 0·000,02, 0 000,002, 0 000,000,2, 0 000,000,02, and 0·000,000,002 gramme of fæces. By making cultures from one cubic centimetre of one of these flasks, therefore, it is possible to determine the relative abundance of the various micro organisms present in a given quantity of the fæces The method combines simplicity with delicacy and by its means a material swarming with micro-organisms and at first sight defying quantitative scrutiny can be bacteriologically analysed with a considerable degree of accuracy.

In the three experiments shortly to be described the izal was given in the form of capsules, each of which contained two minims of pure izal oil Not more than three capsules were given at a time. They were given with food, one capsule before and one or two after the meal, according to its size. The largest amount given in 24 hours was 24 minims of the oil. No unpleasant symptoms resulted. It should be noted that Dr. Tunnicliffe did not give his patients more than 15 minims of the izal oil per diem and that one day's pause in four was always allowed. But he was dealing with phthisical patients who were also breathing izal vapour during the night.

The following have been the two main points determined in fæcal examinations. 1. The total number of micro-organisms present in agar plates after 24 hours' incubation at 37° C. 2. The total number present in gelatin plates after 48 hours' incubation at 22° C. In addition to these two factors the following particulars were also examined in some cases. 3. The extent to which fermentation, as evidenced by the presence of gas-bubbles, may occur in a series of gelatin shake-cultures inoculated with successive tenths—i.e., with from 0 02 up to 0 000,000,002 gramme of fæces—and kept for four days at 22° C. This is a rough test introduced in this sense by Dr. A C. Houston.[7] 4. The extent to which growth takes place in broth cultures also inoculated with successive tenths and kept at 37° C. for five days. 5. The extent to which the bacillus coli was present in these broth cultures after 48 hours' incubation at 37° C. 6. The extent to which indol was present in them after five days at 37° C. 7. In the first experiment the virulence of the fæces as evidenced by the virulence of the growth in broth after 48 hours at 37° C. was also determined both before and after taking izal. Three series of experiments in all were made. Experiments I. and II were made on the same subject. There was a pause of 10 days between the end of Experiment I. and the beginning of Experiment II. Experiment III was conducted on a different subject. Both subjects were normal adult males. The results obtained are shown in the following tables where they are expressed in terms per one gramme of fæces:—

*Experiment I.*

| Conditions. | | Analysis 1.—Normal. | Analysis 2.—After 20 minims of izal oil. | Analysis 3.—After 42 minims of izal oil. |
|---|---|---|---|---|
| Since experiment began. | Time ... | — | 24 hours. | 48 hours. |
| | Motion ... | — | Third. | Fifth. |
| Total number of micro-organisms in agar at 37° C. . . .. | | 440,000,000 | 140,000,000 | 60,000,000 |
| Total number of micro-organisms in gelatin at 22° C . .. | | 520,000,000 | 120,000,000 | 140,000,000 |

# ABDOMINAL HYSTERECTOMY FOR CANCER OF THE UTERUS;

### WITH NOTES OF TWO CASES.

By ROBERT O'CALLAGHAN, F.R.C.S. Irel.,
SURGEON TO THE FRENCH HOSPITAL;
AND
HENRI DARDENNE, M.D. Edin., M.R.C.P. Lond.,
PHYSICIAN TO OUT-PATIENTS AT THE FRENCH HOSPITAL.

Case 1. *Cancer of the cervix treated by amputation, followed by pregnancy, necessitating Cæsarean section with complete hysterectomy.*—On March 11th, 1901, Dr. Dardenne was called to see a woman who had been married for 17 years and had never been pregnant. She was 36 years of age. When Dr. Dardenne saw her she complained of pain in the hypogastric region and also of a muco-sanguinolent discharge of a fœtid odour. She was uncertain as to the exact date of the commencement of her present illness, except that four months previously she had a smart attack of hæmorrhage which had compelled her to keep her bed for three days. Ever since she had been troubled more or less with the discharge of which she now complained. Previously to this she had been in good health except for obstinate constipation. Her general surroundings were extremely good and had always been so. Her family history was good. Her facial expression was somewhat anxious and her complexion was pasty. She was stout in body and had no idea that she was seriously ill. There was no œdema; in fact, no morbid appearances could be detected. The temperature was normal; the pulse was 80. On making a vaginal examination, Dr. Dardenne noted at the time that the cervix was invaded by a hard cauliflower growth, and at the back of this there was a crater-like fissure on the right and a similar fissure was present on the anterior and posterior surface of the cervix. On bimanual examination a hard mass of indurated glands was felt in the right iliac region. The bladder gave no trouble to the patient. Dr. Dardenne diagnosed cancer of the cervix and advised her to become an inmate of the French Hospital. This she did and when seen the next day by Mr. R. O'Callaghan he confirmed the diagnosis and operated on the following day. With the knife and cautery he removed all that was possible of the affected tissues. The disease being so far advanced he did not think that a hysterectomy would be of much benefit to the patient. She left the hospital on March 30th. On Nov. 2nd Dr. Dardenne saw the patient again and on examination found that she was five months pregnant. She had quickened a fortnight before. Since the operation she had some slight bleeding which she attributed to her periods. On Dec. 24th labour pains came on and she entered the French Hospital on Christmas Day. The whole of the lower segment was one mass of cancer and after 18 hours of labour pains the little finger could not be introduced through the hard mass. At 8 P.M. Mr. O'Callaghan performed a Cæsarean section. An incision four inches long was made in the middle line and the uterus was brought well forward and incised; the child and the placenta were rapidly extracted without any difficulty; there was some sharp hæmorrhage which was easily controlled by the house surgeon. The greatest difficulty experienced was now to be met with in the complete removal of the uterus. The new growth having destroyed all landmarks made it difficult to get into the vagina safely without injuring the bowel, the bladder, or the ureters; this, however, was done successfully, after very tedious manipulation owing to the very fat parietes. The ligatures were brought into the vagina and the peritoneal vault was sutured, the abdominal wound was then closed, and the patient was quickly removed to bed, having borne the operation very well. She, however, never seemed to rally from the shock and died in 48 hours.

Case 2. *Cancer of the cervix complicated by cystic ovary and adhesions treated by complete abdominal hysterectomy.*—A woman, aged 34 years, came to Dr. Dardenne in the out-patient department of the French Hospital on Dec. 9th, 1901, complaining of a bloody discharge from the vagina which had been preceded for about three years by a muco-purulent one. She had been married for 18 years; she had had two children, the younger being 16 years of age, and one miscarriage. Menstruation began when she was 15 years of age, and up to three years previously she was quite regular when she had a period lasting for 18 days, and ever since then she had been irregular. Her family history was good. She was admitted into hospital under Mr. O'Callaghan and on the following day she was examined under ether. The uterus was fixed and the cervix was enlarged and of a dark-red colour; bimanually the uterus was found to be enlarged and an enlarged ovary was felt on the left side. The uterus was fixed and could not be brought down to the vulva. A portion of the posterior lip was removed with the knife and sent to the Clinical Research Association. Mr. J. H. Targett reported that it was an epithelioma. The patient having given her consent for the removal of her uterus she was operated upon on Jan. 10th, 1902. The abdomen was opened by a three-inch incision. The right ovary, which was cystic, was removed as well as the left, when it was freed from adhesions. The uterus was with difficulty freed from old adhesions, then well drawn out and removed in the usual method. The ligatures were drawn into the vagina, and as there was considerable oozing a strip of cyanide gauze was passed into the vagina for a drain. The peritoneal vault was closed over all and the abdominal wound was sutured in two layers. The patient made an easy recovery.

*Remarks by* Mr. O'Callaghan.—In Case 1 it is interesting to note that after 17 years of barrenness this poor woman became pregnant after amputation of her cervix for malignant disease followed by a thorough efficient use of the cautery. It was a matter of regret that she did not come into hospital, as we had arranged she should do, before labour, which came on at seven months, and she was, unfortunately, in labour for 18 hours and the membranes had ruptured (an important factor as regards the result). She was very tired as a consequence and for an hour before operation, while finding me and an anæsthetist, the house surgeon gave her frequent inhalations of chloroform. It was an emergency in which the difficulties were, I am glad to say, rare. The patient never seemed to rally from the shock of the operation, although she was given hypodermic injections of strychnine sulphate by Dr. H. Leclezio, and despite his unremitting care she died in 48 hours. A post-mortem examination could not be obtained, but the right breast was found to contain a new growth which had affected the axillary glands. Such cases are, fortunately, rarely met with, and demand prompt action if only to prolong life for a little while. A simple Porro's operation, and fixing the stump of the uterus in the abdominal wound might have saved shock and prolonged life in this case for a short time, but it would not have been a good precedent.

In Case 2, although the uterus was fixed and could not be drawn down into the vagina the history of the case and the appearance of the growth suggested chronic endometritis with erosion more than epithelioma. As it would have been very difficult, if not impossible, to remove the uterus by the vaginal route I decided to do a complete abdominal hysterectomy. The appendages on both sides were adherent and one ovary was cystic. This caused a good deal of venous oozing which was treated by packing with a strip of gauze, leaving the end in the vagina; this drain was removed in 48 hours, the patient making an uninterrupted convalescence. I have no hesitation in saying that when the uterus is at all fixed the abdominal route is the method of selection in these cases, as the operation is more satisfactory from a surgical point of view, and the ovaries and tubes can be removed, no matter how large or adherent they may be, which I hold should be done in all cases of hysterectomy, as they are absolutely useless after the removal of the uterus and can only become nuclei for further pelvic mischief.

I have to thank the house surgeon for his efficient assistance in these cases and for his intelligent preparation and after-care of them.

---

# ELECTRIC SHOCKS.[1]

By F. B. ASPINALL.

I bring this question before the institution principally with a view of obtaining particulars of severe electric shocks which have not proved fatal, and therefore I trust that any one who from his own experience can give particulars of cases will kindly do so. My reason for trying to obtain this

---

[1] A paper read before the Institution of Electrical Engineers on Feb. 27th, 1902.

The idea of using urea pura for lupus suggested itself to my mind after reading a most interesting paper by Dr. H. Harper[1] of Nottingham on the value of pure urea in phthisis. I had in my wards at the asylum two very bad cases of lupus vulgaris, and I decided to put them both on urea and to give them daily exposures to the x rays. Photographs were taken before and after the treatment.

The general outline of the treatment employed was as follows:—On May 21st, 1901, in the one patient, and on June 7th, 1901, in the other, I ordered urea in 20-grain doses three times a day and commenced the exposures on these dates respectively. The x-ray apparatus used was a 10-inch coil, with a platinum interrupter, and a Crookes's focussing tube with a spark length of six inches The exposures were made daily and were of seven minutes' duration, at a distance of from two to three inches from the face. The voltameter registered 12 volts and the indicator of the galvanometer oscillated between four and six ampères. It was never found necessary to protect the healthy skin from the rays, as the only effect produced was a slight red areola round each scab.

In the July number of the *Practitioner* Mr. A. H. Buck, of the Sussex County Hospital, published a paper entitled "A Case of Lupus of 12 years' standing Treated with Urea Pura and Cured." I read this monograph with great interest and found that his treatment differed from mine in that he combined cod-liver oil and malt extract with the urea and applied some ointment as a local dressing, the Roentgen rays not being used at all.

CASE 1.—The patient, a woman, aged 30 years, was admitted into the Kent County Asylum on Feb. 1st, 1901. The following note, taken from the case-book, shows her condition on admission: "She is demented and quite lost to her surroundings. She is weak, badly developed, and poorly nourished. She has chronic lupus of the face. There is a suspicion of tubercle at the right apex. The heart's action is weak." The lupus extended from ear to ear, spreading out like the wings of a butterfly. These two areas were connected by extension of the disease over the bridge of the nose and the upper lip. The whole of the cartilages forming the tip had ulcerated and the lower ends of the nasal bones were visible through the weak and indolent tissue. The glands of the face and of the submaxillary and cervical regions were enlarged on both sides, but especially on the left. There was distinct softening in some and fluctuation could easily be felt. The softening had proceeded so far in the one immediately in front of the left ear that just as I was exposing the photographic plate the pus burst through the skin and ran down the face. The patient was unable to breathe through the nose, owing to blocking of the nasal passages by dried mucus and pus. Her breath was extremely foul, and she was very weak and anæmic. Her pulse was soft, weak, and rapid. The action of her heart was very feeble There was slight impairment of the percussion note over the right apex The breath sounds were somewhat harsh. The patient's weight was six stones five pounds. The dose of urea at first was 20 grains three times a day. It was gradually increased up to November, when the patient was taking as much as 120 grains three times a day. Since July I have followed Mr. Buck's example and added cod-liver oil and malt extract to the mixture. On Sept. 30th, 1901, as all active signs of the disease had disappeared, the exposures to the x-rays were discontinued, and since that time the redness has gradually subsided, and a thin, smooth, white scar now occupies the place of the apple-jelly nodules and ulceration. On examination of the chest on March 2nd the difference in the percussion note was so slight that had I not the knowledge that the right lung had been affected I should have said that there was no difference. The breath sounds were not quite pure on the right, but they were not so harsh as when the patient was admitted. The heart sounds were regular and of normal volume. The pulse was 78, regular, full, and well maintained. She has recovered from her anæmia. She sleeps well and eats well, and is altogether in very much better general health. She takes some interest in things going on around her, talks a little, and is, as a matter of fact, much more trouble to manage than on admission. There was no increase in the percentage of urea in the urine, for out of several estimations the highest percentage found was 2 (the normal). Her weight is six stones six pounds.

CASE 2.—The patient, a woman, aged 30 years, was admitted into the Kent County Asylum on March 1st, 1901. The following are notes from the case-book taken on admission: "She is demented. No evidence of mind. She never speaks. Cannot make her wants known in any way, and is most filthy and degraded in her habits. She is very weak, badly developed, badly nourished, and very anæmic. Has lupus on face. Heart's action rapid and weak. Lungs very weak. Weight five stones 13 pounds." When the treatment was commenced on June 7th she was in a very low condition. Her face was one mass of ulceration and dried scabs Her eyelashes were turned inwards and swept the cornea. Pus welled out of both eyes from the conjunctivæ, which were red and inflamed. Her eyes were directed downwards and inwards. It was very doubtful whether she could see or not. On the left side of the nose, over the situation of the nasal duct, was a small sinus from which thick creamy pus exuded. Her upper lip was enormously swollen and protruded one and a half inches beyond the lower. The mucous membrane of the nose was red, swollen, and ulcerated Her breath was very foul-smelling. The submaxillary, cervical, and supraclavicular lymphatic glands were greatly enlarged, many being in a condition of softening Almost the whole of both cheeks were involved in the disease. For the first fortnight I had the face dressed with olive oil night and morning to soften the scabs, which I then removed with a pair of forceps and a warm solution of chinosol. This was the only local application, and was discontinued as soon as all the scabs had been removed. She never spoke but made unintelligible sounds, and this I believed was due to the enormous size of the upper lip and the blocking up of the nose with dried mucus and pus. The dose of urea was gradually increased from 20 grains three times a day to 120 grains three times a day, and, just as in the last case, since July cod-liver oil and malt extract have been added. She had exactly the same Roentgen-ray treatment as the first case, but she improved much more rapidly, and as a result the exposures were discontinued on Sept. 3rd. I think that this is accounted for by her not having had the disease for such a long time as the other patient had. Since that time the redness due to the exposures has gradually subsided, and at the time of writing (March 2nd) a smooth white scar occupies the place of the ulcerated surface. There is no discharge from the eyes, and the sinus over the nasal duct has quite healed. Her lip has returned to its normal size and she speaks quite distinctly at times. She can see very well and appears to take much more interest in her surroundings. It was impossible to get a 24 hours' specimen of this patient's urine, so I have been compelled to make my estimations from the specimens which I could secure, no matter how small the quantity. But in no case did I discover more than the normal percentage of urea, the average being about 1·7. There are no signs of phthisis in the lungs The heart sounds are normal. She has gained flesh, sleeps well, eats well, talks, chatters, and sings, and at times she is very violent and troublesome. Her weight is five stones 13 pounds.

*Remarks.*—The points to which I particularly wish to draw attention are: the low-pressure tube used (viz., six inches) and consequently the absence of any severe dermatitis in the neighbouring healthy skin; secondly, the comparatively short duration of the treatment and the small amount of trouble entailed in carrying it out; thirdly, the great improvement in the general health—lungs, heart, mental condition, and anæmia; and, lastly, the absence of all puckering of the skin and unsightly contractions, so commonly seen in cases treated by the older method of scarification. The great objection undoubtedly is the expense of the urea.

Maidstone.

REVACCINATION OF TRAMPS.—At the meeting of the Stonehouse Board of Guardians held on Feb. 27th the medical officer (Mr T Leah) stated, in reference to the revaccination of tramps, that unless he inspected the cases afterwards the Local Government Board auditor might perhaps not allow the fees, and he did not wish to keep tramps in the workhouse for a week in order to inspect them. Eventually the matter was referred to the house committee. —The Torrington (Devon) Board of Guardians at its meeting on Feb 22nd decided that all vagrants should be vaccinated on their admission to the workhouse—a procedure which has also been enforced by the Bideford Guardians.

---

[1] THE LANCET, March 9th, 1901, p. 694.

is, I know, a firm belief that the path which the current takes is of the utmost importance, and therefore in handling high-tension apparatus we always try not to make contact in such a way that a vital part is directly in the circuit. To illustrate the different paths which the current can take I will give a few cases which have come under my notice and also what the victim felt most: from hand to hand, a blow in the chest; from the right hand to the right foot, nothing; from the right hand to the left foot, nothing; from the right hand to both feet, nothing; from the left hand to the left foot, a blow in the back of the neck; from the left hand to the right foot, a blow in the back; from the left hand to the head, a blow on the top of the head; and in the case of a current from the head to the buttocks, it could not be ascertained if anything was felt. Of course, I cannot say why they should feel differently, but I bring these facts forward as perhaps medical men can give an explanation. I think, however, that it proves that different organs of the body are affected. Dealing with this part of my subject the following two cases may be given. A man was oiling an alternator and he touched the inner brush accidentally with his elbow; his right foot was on the earthed frame of the machine and his left foot was insulated. The pressure was 2200 volts, and although he gave the cry and was sensible till the circuit was broken he could not get away. He remembered them running to shut the machine down, but became insensible when this was done and was treated for 40 minutes by artificial respiration before he showed any signs of life. One would have expected this man to be killed, but it is only fair to say that he was badly burnt on the elbow and the foot. In the second case a man was adjusting an arc lamp. He had his left foot earthed, and with his left hand he touched the carbons. I am unable to state the number of volts that he received, as I could not ascertain where the current earthed; but he was killed. There was only a slight discolouration noticeable and he was not burnt. I will discuss the question of burning later, but I think it is a fair conclusion that the left side is more vulnerable, and I believe the reason is that the valves of the heart on this side are more easily damaged. To my mind these cases prove conclusively that the path which the current takes is a most important factor.

5. *Does the question of contact made, and whether burning takes place or not, have any effect upon a person's chance of being killed?*—In my opinion the question of contact is perhaps the most important of any arising when a person receives a shock, and I should like to go into it rather minutely. In our ordinary every-day work perhaps the question of contact receives more attention than anything else, as not only is it a question of good contact, but the area of contact must be sufficient to carry the current. Now, when a man receives a shock this is equally true, and although it might be safe under ordinary conditions to work with even a high voltage, yet if he really did his best to kill himself he could most probably manage it with even a small voltage, provided that he had a sufficient area of contact. To illustrate what an important part this area of contact plays I had my resistance measured holding a No. 20 B.W.G. copper wire between the finger and thumb of each hand, and afterwards I connected these two wires to two pennies and held them in the same way. With the pennies my resistance was 20,000 ohms lower. I therefore think if the area of contact were only sufficiently large the resistance would be practically nothing. Of course, if the skin were wet the area necessary to get no resistance would be much less, but as one does not work with wet hands I need not consider the question. On the other hand, if the skin were oily it would be much more.

Another point on which I would lay particular stress is that the area of contact to get the same resistance in different persons would not be the same, and even with the same person in different parts of the body the area of contact would have to be changed. To illustrate this I measured the resistance of six people, picked haphazard, from thumb to thumb, and although I was careful to obtain what I believe was the same amount of contact in each case, yet A measured 30,000 ohms, B 50,000, C 60,000, D 60,000, E 100,000, and F over 100,000. This was due most probably to different thickness and moistness of the skin. As regards the same person, I had my resistance measured from thumb to thumb, which gave 100,000 ohms, but from the heel (where the boot rubs) to the big toe I got 200,000 ohms, although in each case I believe the same contact was made.

The question of area of contact also plays an important part from another cause, as, if the area is small, the chance of burning is largely increased, not only from the fact that heat is generated at a bad contact, but that it is easier to form an arc, which causes the burning to be still more severe. I shall discuss the question of burns by alternating and direct current later, but a direct current burns much more severely, especially at the positive pole.

No doubt it may be questioned why I am laying so much stress upon a point which is thoroughly understood by everyone, but my reason for doing so is that I believe this question of burning is a wonderful provision of nature to protect us against fatal shocks, as the burning not only numbs the nerves and thus prevents us from feeling, but will also, I believe, be found to increase the resistance, thus preventing the current passing. It is impossible for me to experiment on burnt live flesh, but I think it would well repay a medical man to do so. The two following cases may be cited. A man who was working on a high-tension switchboard received a 2000-volt alternating shock and was killed. I myself saw the body and noticed that there was only a slight burn on the left hand, no other mark being found on the body. It was therefore impossible to say how the man really received the shock. I am sure the burn was only slight, and as I have had considerable experience of electrical burns at various voltages (both alternating and direct) I think that I am in a position to judge as to their severity. The second case was that of a man who received a 2000-volt alternating shock from hand to hand and in which death occurred. The engineer on watch at the time told me that only slight burns were on each hand.

In the case already mentioned of a man who was killed on an arc circuit only a slight redness was seen on his hand Of course, this may not always be the case, as it is quite possible that the victim in his struggles to escape may reduce the contact and therefore may cause severe burning after he has received sufficient current to kill him. In previous cases which I have mentioned in which the victim recovered severe burning took place and I shall mention more later.

I know I am laying myself open to severe criticism in bringing forward this theory, as the majority of electrical engineers and also medical men believe that severe burning means a severe shock, and to illustrate this I cannot do better than again quote Dr. Oliver[3]: "If the skin at the time of contact was moist, so much more the burning. If a current sufficient to produce this severe local burning pass through the body fatal results are more probable." My own opinion is, however, from reasons stated above, that moistness of the skin reduces the chance of burning as it ensures better contact, and if no burning takes place efforts to help the victim should be redoubled if it is thought that he has received a shock, as it is quite possible that, owing to this misapprehension, he may be thought to be ill from some other cause. I should like to say a good deal more on this question, but as the time is short I will proceed to the next point.

6 *Can a person receive a fatal shock without giving the "cry," and also can he speak after receiving a fatal shock?*—It may be of interest to attempt to describe the "cry," and as I have heard it three times, and have discussed this matter with others who have heard it, I think it can be accepted that this cry is best described as a rapid drawing in of the breath, followed by a half sigh, half shriek. In each of at least a dozen cases of more or less severe shocks that have been reported to me the victim gave the cry, but in the case in which I personally saw the victim three witnesses were sure that he did not give it.

With respect to the question as to whether a person can speak after he has received a fatal shock I may say that I have always thought this impossible; but in the above case the victim was asked if he was hurt and he said: "I am all right," and yet directly afterwards dropped down dead. Of course, one may ask: Did he really die from an electric shock? but as a post-mortem examination was made and the medical man satisfied himself that all the organs were healthy I think that there can be no doubt about it. I think, therefore, that further information is most urgently required, but at present one can only say that a man need not give the cry and that it is possible for him to speak after a fatal shock has been received.

7. *Is an alternating- or a direct-current shock more likely to prove fatal?*—This question may be looked at from two points of view. First, if a man is killed by an alternating

---

[3] Loc. cit.

information is that I believe we, as electrical engineers, can render great assistance to the medical profession by doing so; and possibly by enabling them to tell us some better methods of rendering aid to those who, unfortunately, are the victims of accident we shall be well repaid.

I have been personally deeply interested in this subject for some years and have collected from my own experience and from that of friends, both in this country and abroad, particulars of as many cases as possible. I have also, whenever I could, made it a rule to see the man who received the shock and also any witnesses All cases, therefore, which I have chosen as of sufficient importance to mention in this paper are, to the best of my belief, thoroughly accurate and trustworthy. In obtaining this information I have been much struck by the fact that it is most difficult to obtain a really accurate description from the victim or witnesses of what actually does occur, and this can hardly be expected when one considers the circumstances; but still, if I only mention what they are absolutely certain about, these cases can be taken as fairly typical.

I should like to say that, not being a medical man, I have no medical knowledge, and therefore I trust that any medical man reading this paper will take this into account if I say anything which to him may seem absurd.

In discussing this question with my personal friends in the electrical profession I find that there are many points upon which more information is required, and therefore these points may be summarised as follows. 1. Is everyone susceptible to an electric shock? 2 Is a person suffering from disease more liable to be fatally injured by an electric shock than a person in good health? 3 Does the physiological condition which a person is in at the time of his receiving a shock make any difference? 4 Does the path which the current takes through the body have any effect as regards the shock proving fatal? 5. Does the question of contact made, and whether burning takes place or not, have any effect as regards the shock being fatal? 6. Can a person receive a fatal shock without giving the "cry," and also can he speak after receiving a fatal shock? 7. Is an alternating- or a direct-current shock more likely to prove fatal? 8 Cannot medical men give us some more certain method of saying whether a man is dead or not? 9. Cannot something more be done than at present to help those who receive a severe shock? I will now proceed to discuss these points separately.

1 *Is everyone equally susceptible to an electric shock?*—In considering this question I believe I am stating the opinion of the medical profession when I say that there is no absolutely reliable proof whether everyone is equally susceptible or not. Dr. T. Oliver[2] says "We have no positive proof that one individual is more susceptible to an electric shock than another. It is, as already stated, rather a question of the amount of current, and whether it wholly enters the body." My own opinion is, and I hope to prove it in this paper, that not only are different people differently affected, but the same person under different conditions does not feel the same. Of course, if one could obtain two people alike in every respect and subject both of them to exactly the same voltage and current, and also in every respect get the same conditions, no doubt they would both feel the same, although they might describe it differently; but when it is considered that moistness, callosity, and condition of skin, nervous temperament, the path which the current takes through the body, health or disease, drunkenness or sobriety, whether the sufferer is awake or asleep, area, the excellence and nature of contact, familiarity with shock, and no doubt other causes, as I shall point out later, all play most probably an important part in deciding what one feels, I think that my opinion will be accepted

2. *Is a person suffering from disease more likely to be fatally injured by an electric shock than a person in good health?*—As an electrical engineer this is a most difficult matter for me to discuss; but from cases which have come under my own observation, and which I have heard of from friends, in whose veracity I can place the most implicit confidence, I think I can prove that this question is of the utmost importance. Some years ago a number of friends were in the habit of measuring their resistance periodically, and it was found that one man was always the lowest, although they all varied. This man was also abnormally sensitive to an electric shock, as he could feel even so low a voltage as that from three Leclanché cells. It was afterwards found that he was suffering from kidney disease, and although I should very much like to measure the resistance of others similarly affected I am afraid to do so in case I might injure them. This seems to indicate that the resistance of the body may be altered by disease, and it is most probable that the skin, by fulfilling the functions which by rights belong to the kidneys, had a lower resistance due to the impurities thus removed from the body. (It is well known that in kidney disease medical men give medicine to make the skin help the kidneys) In a central station with which I was connected it was the habit of the men to give an electric shock from a magneto-machine to visitors, and although it was found that different people seemed to feel differently, yet one boy could stand more than anyone else. He was, however, unfortunately of weak intellect. Another case of which I heard was at a bazaar where money was placed in a bowl of water charged from a Rhumkorff coil. One woman took the money out every time and had to be paid to go away, as she nearly made them bankrupt. She also was of weak intellect. No doubt this insensibility was due to the brain being affected. It appears, therefore, fair to say that a diseased person may be either more or less susceptible according to what disease he may be suffering from.

3. *Does the physiological condition which a person is in at the time a shock is received make any difference?*—The first point which naturally occurs is, Does a person in a heavy perspiration stand a better chance than one who is in a normal condition? and to illustrate this I think I may quote the following case A man had been doing very heavy work which made him perspire freely; to rest himself he sat down on a transformer, which was earthed, and in leaning back his head touched an inner terminal; as the outer was earthed he received a 2000-volt shock. He was wearing a thick flannel shirt, which was wet with perspiration. The result was that he received a most severe shock, a hole being burnt in his trousers, and the back of his head and his buttocks were severely burnt. This man, I think, should have been killed, but he was not even insensible. Surely, this seems to show that the sweat shunted the current, thus saving his life; although the burning probably protected him, as I will show later.

Again, would a man, when drunk, be less liable to be fatally injured? and to illustrate this I give the following case. A man working in a transformer station as a labourer touched an inner terminal with one hand and an outer with the other, the potential difference being 2000 volts. It was found out afterwards that this man was a heavy drinker and was under the influence of drink when he received the shock, which did not even make him insensible. It is only fair, however, to state that his hands were exceptionally callous, due to the fact that he had been working as a gas stoker, and also that his hands were severely burnt. Personally, however, I think he received quite enough to kill him, and that his being drunk had something to do with his not being killed

Next, Are persons less liable to be killed when they are asleep? Some years ago I was carrying out a contract which necessitated all the work being done at night. One of the men employed was always going to sleep, so the other men as a practical joke gave him a shock whilst he was in this condition from a magneto-machine capable of ringing through 30.000 ohms, but although they tried all they could he did not awake. As they thought that this was peculiar the men called my attention to it, and I personally saw him receive a shock without taking any notice of it. I may also say that I arranged for my assistant to give me a shock when I was in bed asleep, and although two witnesses guaranteed that he had done so I felt nothing. Illustrating this, I should like to mention the following case A man was stationed to watch a cable under test charged to 5000 volts, and going to sleep he fell on to it. He was most severely burnt about the hands but was not killed.

Of course, with so few cases it is impossible for me to say that my deductions are absolutely correct, but I bring them forward as I think that they are of profound interest both to the electrical and to the medical professions.

4 *Does the path which the current takes through the body have any effect as regards the shock proving fatal?*—Although I have been present in three cases where a medical man was called in to attend to a man who had received a severe shock I have never been asked where the current entered and left the body, and this, to me, has always been a complete puzzle, as amongst all electrical engineers there

---

[2] Allbutt's System of Medicine, vol. v., p. 856.

The question, therefore, which I wish to ask the medical profession is, Should we adopt the same treatment as is used for collapse from chloroform, and when a man receives a shock should we, before applying artificial respiration, hold the body for a few seconds head downwards at an angle of 45°, thus flushing the brain and stimulating its action? I bring this theory forward with the greatest diffidence, but as I have actual cases to bear me out and also other evidence which points the same way, I think that, considering its vital importance to humanity, I am justified in doing so in the hope of its being investigated by the medical profession, but until this has been done no one realises better than myself that my evidence cannot be considered as conclusive.

In conclusion, I can only say that I am fully aware of the shortcomings of this paper, but it is a real attempt possibly to save a human life by thus endeavouring to get members to give information on this question which so immediately concerns us as electrical engineers.

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### LATENT VACCINIA.

By J. W. Washbourn, C.M.G., M.D. Lond.,

PHYSICIAN TO GUY'S HOSPITAL AND TO THE LONDON FEVER HOSPITAL, ETC.

THE patient, a girl, aged two and a half years, was vaccinated two years ago in four places, only one of which took, and that very slightly. She was seen by Mr. Percy Rose on Feb. 3rd, with the history that she had been ailing for three days. The tonsils were red and swollen, and the sub-maxillary glands on one side were enlarged; there was some stomatitis, and the temperature was 102° F. On the 4th Mr. Rose was informed that "marks" were coming out over the old vaccination sites. On the 5th he saw the patient and found the temperature to be 101·4° F. There were exudation on the left tonsil and a scarlatiniform eruption over the chest and the back. A younger child was also ill with an injected throat, vomiting, and a scarlatiniform eruption. The diagnosis of scarlet fever was made. On inquiry of the mother the following history of the vaccination spots was elicited. On Jan. 31st, the day on which the child was first taken ill, a dry sore was observed on the left arm at the site of the original vaccination; the mother was quite sure that no marks were previously visible. On Feb. 2nd three fresh red places with a scab over them were observed. On the 5th Mr. Rose found that there were four spots on the left arm at the usual site of vaccination; they were all of about the same size as a vaccination lesion, and each of them was surrounded by a small red areola with a thin dry scab in the centre. The appearance was exactly that of mild vaccination at about the seventh day.

I saw the patient on Feb. 7th with Mr. Rose and confirmed his observations. The mother was quite certain that the spots were at the site of the old vaccination, and she was sure that the child had not been recently vaccinated and that nothing had occurred before Jan. 31st On examining the child there was very slight impetigo of the scalp and the skin was clear elsewhere. The appearance of the marks on the arm and their arrangement were quite unlike anything in the way of secondary infection from impetigo. There was no doubt that the child was suffering from scarlet fever, and the only explanation that we could give was that the vaccination had remained latent during two years and had started afresh with the onset of scarlet fever.

Cavendish-place, W.

### NOTE ON THE DISCOVERY OF A NEW TRYPANOSOMA.[1]

By D. Bruce, M.B., C.M. Edin., F.R.S.,

LIEUTENANT COLONEL, ROYAL ARMY MEDICAL CORPS.

I HAVE received from South Africa specimens of blood taken from cattle which contain a new species of trypanosoma. This new species can be at once distinguished from the trypanosomas of surra, of tse-tse fly disease, or of the rat by its larger size, it being almost twice as large as any of the others. In general appearance it conforms closely to the others in possessing an oval protoplasmic body, a longitudinal fin-like membrane, and a single flagellum. This new trypanosoma was lately discovered by Dr. A. Theiler, who is in charge of the bacteriological laboratory of the medical officer of health, Pretoria, Transvaal. He states that at first he was under the impression that he had merely hit against the familiar trypanosoma of tse-tse fly disease. He, however, was struck by its larger size and he tried a few inoculation experiments. He found that the new trypanosoma only infected cattle. Horses, dogs, goats, rabbits, and guinea-pigs were all immune, neither showing symptoms nor the presence of the parasites in the blood. With the same blood he infected two calves, which showed distinct febrile reaction, and at the same time the parasites appeared in the blood. He found the parasite for the first time in the blood of a young ox which had just recovered from an attack of rinderpest, and since then he has successfully inoculated calves from two other cattle. He describes the disease as an acute pernicious anæmia with grave blood changes, a general anæmia without deformation of the elements of the blood, or, lastly, only a slight fever. He also believes that there exists a natural immunity in cattle against this trypanosoma. He is of opinion that this disease is the same as that attributed by Dr. Kolle—who studied rinderpest in South Africa with Koch during the last outbreak—to bovine malaria. Dr. Kolle overlooked the trypanosoma, saw that the disease was infectious, and thought that he observed endoglobular parasites and pigment in the red blood corpuscles.

As this discovery seems to me to be an interesting one, and as Dr. Theiler deserves great credit for the observation, I would propose that this trypanosoma be named after the discoverer *Trypanosoma Theileri*.

### A CASE OF REDUPLICATED CARDIAC IMPULSE AND SOUNDS.

By John McClymont, M.D. Edin.

THE following case illustrates the assistance which the Roentgen rays may afford us in connexion with certain cardiac abnormalities.

A gardener, aged 33 years, with no previous special history, consulted a medical man in regard to an attack of coryza On examination of the chest the cardiac rhythm and sounds presented such unusual features that the medical man formed the opinion that the heart was diseased. This fact coming to the knowledge of the patient's employer he lost his situation and was next at new work as a coalman in London. He did this laborious work with such obvious impunity and in perfect health that he resolved to have his heart re-examined with the prospect of returning to his former pleasanter occupation and in this way came under my notice. The man presented himself in perfect health and without any cardiac symptoms. There was a double cardiac impulse of regular occurrence in the normal position, the second slighter impulse immediately following on the heels of the first There was no increase of præcordial dulness There was a slight impurity of the first sound in the aortic area, and the sounds, like the impulse, were reduplicated. This was specially clear at the apex, the second group being like an echo of the first or louder sounds. There was, however, no reduplication of the pulse. The complete absence of any cardiac symptoms, the lack of either hypertrophy or dilatation of the heart, and the unfailing regularity of the second impulse did not suggest the missed beat of a played-out organ.

Through the kindness of Dr. Betrand Dawson and Mr. Harnack, the superintendent of the radiograph department at the London Hospital, I was able to see the working of this heart on the skiagraph screen. There was the first systole dilating the great blood-vessels and causing the pulse wave and first strong cardiac impulse. The apex remaining all the time in systole, there then occurred a second contraction of muscular fibres, principally or alone at the base of the ventricles. The great blood-vessels were not dilated by this contraction, but it doubtless gave rise to the second cardiac impulse and to the fainter, echo-like heart sounds This peculiar condition of secondary fibrillar contraction was no doubt due to some irregular innervation of the cardiac muscle and was not of the nature of the missed beat of a failing organ.

Leyton, Essex.

---

[1] A paper read before the Royal Society on Feb. 27th, 1902.

shock, would not a direct-current shock prove equally fatal provided the conditions in each case were exactly the same? Secondly, is there anything in the actual working conditions which makes one supply more dangerous than the other? Considering this from the first point of view, the question immediately occurs, Do both kinds of shock affect the body in the same manner from a medical standpoint? Of course, I am not in a position to judge, but as a direct-current causes electrolytic action, and an alternating-current does not, it seems that more must take place with direct-current than with alternating-current shock. It is also open to discussion whether, disregarding electrolytic action, the two act the same, as the alternating-current shock from its nature must have a spasmodic effect, whilst a direct-current shock seems to paralyse at once. From my own experience of shocks, I am certain that the after-effect of a direct-current shock is worse than that of an alternating current. When looking at the matter, however, from an electrician's point of view, I can see a great difference, as there is no doubt that if contact is made with metal of such a shape that it cannot be gripped, and the current passes from hand to hand, the direct-current shock seems to knock the victim down, whilst an alternating-current shock seems to draw him closer and to tie his body as far as possible into a knot. On the other hand, if he can grip the metal the direct-current shock seems to hold him tighter than does that of the alternating current. Of course, I am only judging from what I have seen and felt myself.

Another influence which I believe plays an important part is the different action which the two currents have in breaking down a fault. For instance, if the insulation is faulty when current once commences to pass, the direct current will break a fault down quicker than an alternating current. No doubt this has some effect when a shock is received, as most probably the direct-current shock would reach its maximum before the alternating-current shock, and, therefore, if a person were only in circuit for a short time, the direct-current shock would have the greatest effect. On the other hand, more burning will take place with direct-current shock than with that of the alternating current, and, as I have pointed out before, this is most probably a protection. My own opinion is that both currents will kill a man equally well, provided that the conditions are the same, and that death ensues from an electric shock.

Although not strictly included in this paper, I should like to draw attention to the fact that an arc is more easily started with direct than with alternating current, and that when once started it is more easily maintained. This is evident from the fact that a fuse which is quite safe on alternating- is utterly useless on direct-current circuits. From the above cause it is possible for a man to be severely burnt on a continuous current, and, therefore, all cases of exceptionally severe burning, if they occur on a low-tension supply, should be thoroughly investigated to prove whether death occurred from a shock due to burns or from an electric shock. The conclusion which I come to is that if death occurs from an electric shock, both are equally dangerous; but if death occurs from burns the continuous-current shock is more dangerous. To make myself thoroughly clear, I should also like to say that although burns are a protection against electric shocks, yet if carried to extremes they may themselves cause death due to shock.

In considering the second question, it must be remembered that although the majority of deaths from electric shocks occur with alternating currents, yet the potential usually worked at with an alternating current is higher than with a direct current, and therefore the conditions required to cause death have to be more favourable with direct current than with alternating current.

Taking the actual voltage required to cause death, independently of nature of supply, I should say that at below 600 volts the conditions must be abnormally favourable; at below 1000 volts they must be favourable; and at above 1000 volts the higher the pressure the more easy it is to get the conditions necessary to cause death. In comparing the relative dangers of the two sources of supply, it must be remembered that even with the same voltage and conditions it is quite possible to meet with an accident from quite different causes due to the kind of supply. For instance, with an alternating supply where the outer is earthed, nine times out of 10 a shock is received, not by getting into the circuit proper, but by touching some metal which has become charged owing to its not being properly earthed or to not realising that any earthed metal is practically the outer. I think, however, that accidents from this cause will be fewer in the future now that the precautions required are thoroughly understood, and, more important still, that we are able to obtain trained men. On the other hand, with direct current, most accidents occur due to an earth on circuit causing a man to receive a shock when he accidentally earths the circuit in another place through himself.

The conclusion which I come to is that there is nothing more dangerous in one system than in another. It is purely a question of voltage and of the conditions being favourable, and it must be remarked that as many conditions have to be favourable it is really so difficult to get killed, even with a high voltage, that practically, with our present knowledge, the chance of this occurring is no greater than in numerous other occupations where a person is likely to meet with an accident.

8. *Cannot medical men give us a more certain method of ascertaining whether a man is dead or not?*—In the *Electrical Review* Rules, which I consider most excellent and, indeed, invaluable, it is recommended to ascertain if the sphincter muscle is relaxed; but as this is for obvious reasons objectionable, and also to a non-medical man most difficult to judge, I ask medical men if they can tell us some better method. If they only knew what one feels when, after doing all one knows to restore a fellow-worker to consciousness, the question arises, Am I simply manipulating a dead body? I feel sure that they would do all they could to tell us how to arrive at a definite conclusion.

9. *Cannot something more be done to help those who receive a shock?*—In discussing this question the first thing which strikes me is how utterly we engineers are in the dark as to what really happens to a human body when death is caused by electricity. Of course, death is a stoppage of the functions of the body, and, looked at from an engineering point of view, I think the organs of the body can be best described as follows—namely, the lungs as the boiler, the heart as a pump, and the nervous system as the mains to transmit signals from the controlling power (the brain) to the various machinery operated, and the arteries and veins as feed-pipes. Now, to my mind, what we want to know is, what breaks down when a shock is received? Are the lungs so damaged that they are useless for further work? or is the pump, the heart, broken in any way that it cannot work—for instance, are the valves ruptured or the arteries (viz., the feed-pipes) broken? or is the blood (the feed water) so decomposed that it precipitates and chokes the pipes? or cannot signals be sent from the brain, owing to the nerves being paralysed? or what happens? Looked at from this point of view, the first thing which requires clearing up is, Are the conditions found inside the body different when death has been caused by electricity from those found when it occurs from shock from fright, excitement, burns, amputation of a limb, &c.? Of course, I, personally, cannot say, but from medical evidence which I have read it appears as if the only thing which is unusual is that the blood appears different post mortem; but I believe that this is open to discussion. I myself think, however, that when it is considered, as I have pointed out previously, that an idiot does not seem to feel a shock so severely as an ordinary person, and also that during sleep less is felt, the truth will probably be found to be that electricity acts like an anæsthetic, such as chloroform. My reasons for believing this are also due to the fact that in two cases of an electric shock where death would have been expected the men recovered, in my opinion, from the head being lowered, thus flushing the brain with blood, which is exactly what medical practitioners do when they want to revive a patient who has collapsed when under chloroform. The cases I give in this connexion are as follows. A man received a 2000-volt shock from hand to hand, but was not badly burnt. He was insensible; his heart could not be felt beating and his breath did not cloud a mirror; his eyes were turned so that the white of the eyes only could be seen, his jaw was dropped, and thus seeing the man I could have been certain that he was dead. This man gave the cry and an engine-driver who picked him up stood him on his head and thumped his chest, his reason being, as he put it, to start the blood flowing, and, as the heart is a pump, to free the valves if they were stuck. After 45 minutes' artificial respiration this man recovered. In another case a man received a 2000-volt shock from hand to hand. He was standing on a pair of steps. As no one was present I cannot say if he gave the cry, but at any rate he fell head first off the steps about four feet to the floor. He came round without assistance in about 25 minutes. It is fair to say that his hands were badly burnt.

The question, therefore, which I wish to ask the medical profession is, Should we adopt the same treatment as is used for collapse from chloroform, and when a man receives a shock should we, before applying artificial respiration, hold the body for a few seconds head downwards at an angle of 45°, thus flushing the brain and stimulating its action? I bring this theory forward with the greatest diffidence, but as I have actual cases to bear me out and also other evidence which points the same way, I think that, considering its vital importance to humanity, I am justified in doing so in the hope of its being investigated by the medical profession, but until this has been done no one realises better than myself that my evidence cannot be considered as conclusive.

In conclusion, I can only say that I am fully aware of the shortcomings of this paper, but it is a real attempt possibly to save a human life by thus endeavouring to get members to give information on this question which so immediately concerns us as electrical engineers.

## LATENT VACCINIA.

By J. W. WASHBOURN, C.M.G., M.D. LOND.,

PHYSICIAN TO GUY'S HOSPITAL AND TO THE LONDON FEVER HOSPITAL, ETC.

THE patient, a girl, aged two and a half years, was vaccinated two years ago in four places, only one of which took, and that very slightly. She was seen by Mr. Percy Rose on Feb. 3rd, with the history that she had been ailing for three days. The tonsils were red and swollen, and the sub-maxillary glands on one side were enlarged; there was some stomatitis, and the temperature was 102° F. On the 4th Mr. Rose was informed that "marks" were coming out over the old vaccination sites. On the 5th he saw the patient and found the temperature to be 101·4° F. There were exudation on the left tonsil and a scarlatiniform eruption over the chest and the back. A younger child was also ill with an injected throat, vomiting, and a scarlatiniform eruption. The diagnosis of scarlet fever was made. On inquiry of the mother the following history of the vaccination spots was elicited. On Jan. 31st, the day on which the child was first taken ill, a dry sore was observed on the left arm at the site of the original vaccination; the mother was quite sure that no marks were previously visible. On Feb. 2nd three fresh red places with a scab over them were observed. On the 5th Mr. Rose found that there were four spots on the left arm at the usual site of vaccination; they were all of about the same size as a vaccination lesion, and each of them was surrounded by a small red areola with a thin dry scab in the centre. The appearance was exactly that of mild vaccination at about the seventh day.

I saw the patient on Feb 7th with Mr. Rose and confirmed his observations. The mother was quite certain that the spots were at the site of the old vaccination, and she was sure that the child had not been recently vaccinated and that nothing had occurred before Jan. 31st. On examining the child there was very slight impetigo of the scalp and the skin was clear elsewhere. The appearance of the marks on the arm and their arrangement were quite unlike anything in the way of secondary infection from impetigo. There was no doubt that the child was suffering from scarlet fever, and the only explanation that we could give was that the vaccination had remained latent during two years and had started afresh with the onset of scarlet fever.

## NOTE ON THE DISCOVERY OF A NEW TRYPANOSOMA.[1]

By D. BRUCE, M.B, C.M. EDIN., F.R.S.,

LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

I HAVE received from South Africa specimens of blood taken from cattle which contain a new species of trypanosoma. This new species can be at once distinguished from the trypanosomas of surra, of tse-tse fly disease, or of the rat by its larger size, it being almost twice as large as any of the others. In general appearance it conforms closely to the others in possessing an oval protoplasmic body, a longitudinal fin-like membrane, and a single flagellum. This new trypanosoma was lately discovered by Dr. A. Theiler, who is in charge of the bacteriological laboratory of the medical officer of health, Pretoria, Transvaal. He states that at first he was under the impression that he had merely hit against the familiar trypanosoma of tse-tse fly disease. He, however, was struck by its larger size and he tried a few inoculation experiments. He found that the new trypanosoma only infected cattle. Horses, dogs, goats, rabbits, and guinea-pigs were all immune, neither showing symptoms nor the presence of the parasites in the blood. With the same blood he infected two calves, which showed distinct febrile reaction, and at the same time the parasites appeared in the blood. He found the parasite for the first time in the blood of a young ox which had just recovered from an attack of rinderpest, and since then he has successfully inoculated calves from two other cattle. He describes the disease as an acute pernicious anæmia with grave blood changes, a general anæmia without deformation of the elements of the blood, or, lastly, only a slight fever. He also believes that there exists a natural immunity in cattle against this trypanosoma. He is of opinion that this disease is the same as that attributed by Dr. Kolle—who studied rinderpest in South Africa with Koch during the last outbreak—to bovine malaria. Dr. Kolle overlooked the trypanosoma, saw that the disease was infectious, and thought that he observed endoglobular parasites and pigment in the red blood corpuscles.

As this discovery seems to me to be an interesting one, and as Dr. Theiler deserves great credit for the observation, I would propose that this trypanosoma be named after the discoverer *Trypanosoma Theileri.*

## A CASE OF REDUPLICATED CARDIAC IMPULSE AND SOUNDS.

By JOHN McCLYMONT, M.D. EDIN.

THE following case illustrates the assistance which the Roentgen rays may afford us in connexion with certain cardiac abnormalities.

A gardener, aged 33 years, with no previous special history, consulted a medical man in regard to an attack of coryza. On examination of the chest the cardiac rhythm and sounds presented such unusual features that the medical man formed the opinion that the heart was diseased. This fact coming to the knowledge of the patient's employer he lost his situation and was next at new work as a coalman in London. He did this laborious work with such obvious impunity and in perfect health that he resolved to have his heart re-examined with the prospect of returning to his former pleasanter occupation and in this way came under my notice. The man presented himself in perfect health and without any cardiac symptoms. There was a double cardiac impulse of regular occurrence in the normal position, the second slighter impulse immediately following on the heels of the first. There was no increase of præcordial dulness. There was a slight impurity of the first sound in the aortic area, and the sounds, like the impulse, were reduplicated. This was specially clear at the apex, the second group being like an echo of the first or louder sounds. There was, however, no reduplication of the pulse. The complete absence of any cardiac symptoms, the lack of either hypertrophy or dilatation of the heart, and the unfailing regularity of the second impulse did not suggest the missed beat of a played-out organ.

Through the kindness of Dr. Betrand Dawson and Mr. Harnack, the superintendent of the radiograph department at the London Hospital, I was able to see the working of this heart on the skiagraph screen. There was the first systole dilating the great blood-vessels and causing the pulse wave and first strong cardiac impulse. The apex remaining all the time in systole, there then occurred a second contraction of muscular fibres, principally or alone at the base of the ventricles The great blood-vessels were not dilated by this contraction, but it doubtless gave rise to the second cardiac impulse and to the fainter, echo-like heart sounds This peculiar condition of secondary fibrillar contraction was no doubt due to some irregular innervation of the cardiac muscle and was not of the nature of the missed beat of a failing organ.

## GERMAN HOSPITAL, DALSTON.

### SOME CASES OF ELEPHANTIASIS OF THE EXTERNAL GENITAL ORGANS FOLLOWING THE REMOVAL OF THE INGUINAL GLANDS.

(Under the care of Dr. J. P. ZUM BUSCH.)

ELEPHANTIASIS of the external genital organs not the result of the filaria sanguinis hominis is certainly rare. It is obvious that it may follow any extensive obstruction of the inguinal lymphatics; and that it does not more commonly follow removal of the inguinal glands is probably to be attributed to the fact that it is very rare for all the glands to be removed. The question of treatment is difficult. Some improvement follows removal of much of the hypertrophied tissue, but in many cases as the lymphatic obstruction continues there is a great tendency to a re-formation of the condition. In this connexion a case shown by Mr. R. J. Godlee at the last meeting of the Clinical Society of London is of interest. A man had obstruction of his thoracic duct with consequent dilatation of the inguinal lymphatics. Mr. Godlee, acting on a suggestion of Dr. P. Manson, effected an anastomosis between one of the dilated lymphatics and the saphenous vein, with the result that the dilated lymph-vessels subsided. A similar operation in some forms of elephantiasis of the scrotum and penis might lead to an equally successful result.

CASE 1.—A man, aged 21 years, was admitted into the German Hospital in April, 1893, suffering from soft sores and lymphadenitis in both groins. Whilst the bubo on the left side became smaller and painless, that on the right side showed signs of suppuration and had to be incised. The patient was discharged by the end of May, but was re-admitted shortly afterwards owing to the formation of a fistula on the right side; the glands of the left side had also become re-enlarged and painful. As incisions and scrapings which were undertaken several times did not effect a cure, the whole of the remaining glands (which were swollen and dotted with numerous small abscesses) with the surrounding tissues were removed by two operations in the middle of August. The operations proved lengthy and difficult, but the large vessels were not injured. Both wounds healed by granulation and the patient left the hospital in October apparently quite well. Three months later (January, 1894) he first noticed an occasional œdematous swelling of the prepuce which disappeared on applications of lead lotion. Gradually, however, the œdema recurred more frequently, extended over the penis and scrotum, and became persistent. When the patient presented himself again at the hospital in April, 1894, the scrotum was as big as two fists, the skin being hard and greatly thickened; the penis was about twice its normal size, the prepuce being especially enlarged, and the whole region was in a condition of chronic elephantiasis. In spite of different methods of treatment this condition had remained unchanged up to June, 1901, when Dr. zum Busch had an opportunity of examining the patient for the last time. Surgical interference of any kind was firmly refused.

CASE 2.—A young man, aged 20 years, was admitted into the German Hospital in March, 1896, suffering from double-sided bubo of long standing. The integument of both sides was inflamed and perforated by many fistulæ and the superficial and deep glands of the inguinal and crural regions were enlarged and fixed. Whilst the left bubo was successfully treated by numerous incisions and scrapings that on the right side showed no signs of improvement and was finally removed by an extensive operation as in Case 1. This patient remained well for about four months after his discharge from the hospital when the penis and the scrotum began to swell and gradually assumed a state of chronic elephantiasis. In this case, however, the enlargement was much more severe on the right side than on the left. When last seen, in November, 1898, the condition was rather worse than it had been two years previously.

CASE 3.—A sailor, aged 24 years, was admitted into the German Hospital in November, 1901. Dr. Lauenstein of Hamburg, under whose treatment the patient had been from August to November, 1899, has kindly informed me that the patient was operated on for double-sided bubo and that extensive operations were done on both sides, no large vessels being injured. Not very long after his discharge from the hospital the man noticed a gradually increasing œdema, first of the prepuce only, but later attacking the whole penis and the scrotum. On admission into the German Hospital the scrotum was nearly as large as a cocoanut, the penis was three or four times its normal size, whilst the prepuce hung down from the end of the penis like a balloon. In this case the lymph-stream was not entirely obstructed as by elevation in bed the size of the affected parts could be temporarily diminished; the swelling which remained was like elephantiasis in character and was exceedingly hard. As the patient was very anxious to have something done the prepuce was removed, together with a large piece of integument from the whole length of the penis. As the wound healed well and the patient was very satisfied with the result it was decided to operate in a similar way on the scrotum. Unfortunately, however, the patient developed typhoid fever and he had afterwards to be sent to a convalescent home. He is now on board ship again, but has asked for an operation to be performed on his scrotum after his return in spring.

CASE 4.—This case occurred in private practice and is illustrative of other cases. A married woman, aged 32 years, consulted Dr. zum Busch in May, 1901, and gave the following history. Three years previously she was infected by her husband and suffered from a sore in the vaginal orifice followed by suppuration of the inguinal glands. As far as one could judge from the resulting scars very extensive operations had been done in the United States. About three or four months later she developed erysipelas of the vulva which left a permanent enlargement of the labia majora. There was no fever during the erysipelatous state nor was there any marked increase of the temperature during four recurrent attacks in 1900. Each attack left the external genitals more swollen and harder. On examination in May, 1901, both labia and the clitoris were found to be very much increased in size and very hard; they, as well as the mons Veneris, were in a typical condition of elephantiasis. The patient was advised to have the labia removed by operation, but she refused.

*Remarks by* Dr. ZUM BUSCH.—This unforeseen and untoward result of the radical treatment of such cases has not been sufficiently recognised either in the text-books or in the special literature of this branch of surgery. Riedel[1] has published notes of two cases and advises surgeons to avoid too extensive operations in inflammatory conditions of the inguinal glands. Of my own numerous cases of clearing out the inguinal region in bubo and cancer I have so far only heard of two having become subject to chronic œdema and elephantiasis (Cases 1 and 2), but I should not be surprised if there were more such cases, as many of my patients probably left England after having been discharged from the hospital.

I may here add one other case in which the elephantiasis occurred in the upper extremity. The patient, a man, aged 24 years, was admitted into the German Hospital in November, 1900, suffering from chronic brawny œdema of the left upper extremity. The arm was enormously swollen and the skin was hard and in many places scaly; the condition was said to have followed an operation for suppurating axillary glands which was undertaken in France two years previously. There was a long scar in the axilla as well as a smaller one above the clavicle. Such an occurrence seems to be very rare, as I have never seen it following Halsted's operation except when the vein had to be tied or when recurrences implicated the vessels, yet it seems important to remember such cases and to be as conservative as possible in the treatment of extensive inflammatory disease of the glands. The recommendation of some surgeons to remove the whole affected area should never be followed except as a last resource in otherwise incurable cases of bubo in which a radical operation is all the more justifiable as the suppuration

As the patient was very anxious to have something done the prepuce was removed, together with a large piece of integument from the whole length of the penis. As the wound healed well and the patient was very satisfied with the result it was decided to operate in a similar way on the scrotum. Unfortunately, however, the patient developed typhoid fever and he had afterwards to be sent to a convalescent home. He is now on board ship again, but has asked for an operation to be performed on his scrotum after his return in spring.

CASE 4.—This case occurred in private practice and is illustrative of other cases. A married woman, aged 32 years, consulted Dr. zum Busch in May, 1901, and gave the following history. Three years previously she was infected by her husband and suffered from a sore in the vaginal orifice followed by suppuration of the inguinal glands. As far as one could judge from the resulting scars very extensive operations had been done in the United States. About three or four months later she developed erysipelas of the vulva which left a permanent enlargement of the labia majora. There was no fever during the erysipelatous state nor was there any marked increase of the temperature during four recurrent attacks in 1900. Each attack left the external genitals more swollen and harder. On examination in May, 1901, both labia and the clitoris were found to be very much increased in size and very hard; they, as well as the mons Veneris, were in a typical condition of elephantiasis. The patient was advised to have the labia removed by operation, but she refused.

*Remarks by* Dr. ZUM BUSCH.—This unforeseen and untoward result of the radical treatment of such cases has not been sufficiently recognised either in the text-books or in the special literature of this branch of surgery. Riedel[1] has published notes of two cases and advises surgeons to avoid too extensive operations in inflammatory conditions of the inguinal glands. Of my own numerous cases of clearing out the inguinal region in bubo and cancer I have so far only heard of two having become subject to chronic œdema and elephantiasis (Cases 1 and 2), but I should not be surprised if there were more such cases, as many of my patients probably left England after having been discharged from the hospital.

I may here add one other case in which the elephantiasis occurred in the upper extremity. The patient, a man, aged 24 years, was admitted into the German Hospital in November, 1900, suffering from chronic brawny œdema of the left upper extremity. The arm was enormously swollen and the skin was hard and in many places scaly; the condition was said to have followed an operation for suppurating axillary glands which was undertaken in France two years previously. There was a long scar in the axilla as well as a smaller one above the clavicle. Such an occurrence seems to be very rare, as I have never seen it following Halsted's operation except when the vein had to be tied or when recurrences implicated the vessels, yet it seems important to remember such cases and to be as conservative as possible in the treatment of extensive inflammatory disease of the glands. The recommendation of some surgeons to remove the whole affected area should never be followed except as a last resource in otherwise incurable cases of bubo in which a radical operation is all the more justifiable as the suppuration itself will probably destroy all the glands and block up the lymph-channels. In cases of cancer and tuberculosis the surgeon must of course remove the glands with the surrounding tissues as thoroughly as possible; the inconvenience of a chronic œdema weighs light against a possible recurrence.

# STATION FAMILY HOSPITAL, RAWAL PINDI.

## A CASE OF CARCINOMA OF THE RECTUM; OPERATION.

(Under the care of Captain T. H. GOODWIN, R.A.M.C.)

THE choice between the perineal operation of proctectomy and that introduced by Kraske must depend chiefly on the locality and extent of the malignant growth. If the upper limit of the tumour does not extend beyond three inches or so from the anus the perineal route is far preferable, for the operation is distinctly less severe; inasmuch as in such a case the peritoneal pouch does not need to be opened and the risk of peritonitis is greatly lessened. If, however, the growth involves a portion of the rectum covered by peritoneum Kraske's operation, or some modification of it, is needed for the complete removal of the tumour. In the following case the operation itself was a success, death occurring apparently from a secondary deposit in the brain.

A married woman, aged 59 years, was admitted to the Station Family Hospital, Rawal Pindi, on August 29th, 1901, complaining of continuous pain in the region of the rectum and anus which was much increased by defecation. The family history was unimportant. The patient had always enjoyed good health until three and a half months previously when she had an attack of dysentery accompanied by a good deal of tenesmus. Since that time she had experienced an almost constant desire to defecate, the resulting motions being small and blood-stained. She had suffered from constant very severe pain which was much increased by defecation. On examination per rectum a hard nodular mass could be felt within the anal margin; the growth extended completely around the rectal wall and was in the shape of a signet ring, extending for about two and a quarter inches upwards posteriorly and for about half that distance in front. The sacral glands were apparently not enlarged. The general health was fair. No secondary growths could be discovered. The tip of the forefinger could reach above the mass in every direction and the growth was freely movable. Excision of the growth was decided on, the patient herself being very anxious to undergo operation. On account of her age and condition Kraske's method of operation was rejected as being too severe and lengthy in performance. She was placed on a nourishing diet and the bowels were kept opened with mild laxatives.

On Sept. 9th, an enema having been previously administered, the patient was placed under chloroform and was put in the lithotomy position. Captain Goodwin then removed the lower three inches of the rectum by the perineal route, the tissues between the rectum and the coccyx being completely divided. The gut was drawn down and was united to the margins of the incision by a few sutures. The hæmorrhage during the operation was extremely free and many vessels required ligature. The vaginal wall was not invaded by the growth. An iodoform and gauze dressing was applied. On examination of the excised growth it appeared to have been completely removed, with a surrounding margin of healthy tissue. A stained section under the microscope proved the growth to be a squamous carcinoma. On the following day the wound was dressed and appeared to be healthy. From the date of operation to Sept. 30th the patient improved steadily; she was quite free from pain and gained in weight and strength considerably. The wound

healed well and rapidly rectal bougie and the gut

showed no tendency to ight after the opera-

tion she was able to the day.

On Oct. 5th she had over

the lower bowel, the

sciously. On the 9th

some hours, became d

reaction, dilated, and for

were

permitted by the relatives. Examination per rectum revealed no enlarged sacral glands, the wound had healed, and there was no sign of local recurrence.

*Remarks by* Captain GOODWIN.—The eventual termination of the case was extremely disappointing, as, from the absence of local recurrence, the rapid healing of the wour and the early control over the fæces, there appeared to every prospect of a successful result. The chief point interest in the case appears to me to be that, although n enlargement of the sacral glands could be felt per rectum yet the probability is that they were involved to a sligh degree. Had circumstances permitted of an operation by Kraske's method, with complete extirpation of the glands, I believe that the eventual result of the case would have been successful.

## PATHOLOGICAL SOCIETY OF LONDON

*Low Proteid Metabolism.—Proteolytic Enzymes in t Spleen.—Chylous and Chyliform Ascites.—New Urinar Pigments.*

A MEETING of the Chemical Section of this society was held on March 5th, Dr. W. D. HALLIBURTON, chairman of the section, being in the chair.

Dr. VAUGHAN HARLEY and Dr. FRANCIS GOODBODY made a communication on cases of Low Proteid Metabolism. It was popularly believed that when large eaters remained thin they did so because a large proportion of the food taken by them passed through the alimentary tract unaltered, and Dr Harley and Dr. Goodbody brought forward these cases to show that this was not always correct. As a matter of fact, certain individuals had a remarkably low metabolism, so that they actually needed less food than other people. Thi cases were described in which the patients were kept und similar conditions—namely, in bed and having only massag as exercise. The diet in all cases was carefully analysed and the urine and fæces were examined, the fæces being divided into different periods by means of charcoal. A woman, weighing 72 kilogrammes, was found to be able to live on a very small amount of food—in fact, on one pound of mutton per diem. During the seven days of observation she only lost two kilogrammes in weight and during the first six days only one kilogramme. During this time the quantity of nitrogen taken in the diet was 12·16 grammes per diem, while the average output of nitrogen in the urine was 13 51 grammes, so that she lost from the tissues in the body generally one gramme of nitrogen per diem. During this period of seven days she passed only five motions and the charcoal showed that there was a marked delay in the passage of the fæces along the alimentary canal because the charcoal did not reappear till from 60 to 70 hours after having been given. The quantity of nitrogen in the fæces was extremely small, being only 0·48 gramme, while the fat was 1·09 grammes—amounts corresponding, in fact, to those found in fasting individuals by other observers On comparing this woman with a man on a diet of one pound of meat per diem it was found that when he was taking 14 72 grammes of nitrogen per diem in his food he excreted in the urine no less than 22·71 grammes, so that whereas the woman lost only one gramme on an average per diem the man, on the other hand, lost no less than sev grammes of nitrogen. During the four days of observati the man lost two kilogrammes in weight; the nitrogen in th fæces was 0 66 gramme and the fat was 2·43 grammes pe diem. The woman was now put on a very small diet durin two periods of five days each. In the second period of five day she took 6 08 grammes of nitrogen, the diet containing only 4·16 calories per kilogramme. During this time she passed 7 32 grammes of nitrogen per diem in the urine, so that during the five days there was a loss of one gramme of nitrogen per diem from the tissues. During the two periods in which she took this remarkably small diet her average weight was, for the first period 66·8 kilogrammes, and for the

kilogrammes, so that the loss in weight was

## GERMAN HOSPITAL, DALSTON.

### SOME CASES OF ELEPHANTIASIS OF THE EXTERNAL GENITAL ORGANS FOLLOWING THE REMOVAL OF THE INGUINAL GLANDS.

(Under the care of Dr. J. P. ZUM BUSCH.)

ELEPHANTIASIS of the external genital organs not the result of the filaria sanguinis hominis is certainly rare. It is obvious that it may follow any extensive obstruction of the inguinal lymphatics; and that it does not more commonly follow removal of the inguinal glands is probably to be attributed to the fact that it is very rare for all the glands to be removed. The question of treatment is difficult. Some improvement follows removal of much of the hypertrophied tissue, but in many cases as the lymphatic obstruction continues there is a great tendency to a re-formation of the condition. In this connexion a case shown by Mr. R. J. Godlee at the last meeting of the Clinical Society of London is of interest. A man had obstruction of his thoracic duct with consequent dilatation of the inguinal lymphatics. Mr. Godlee, acting on a suggestion of Dr. P. Manson, effected an anastomosis between one of the dilated lymphatics and the saphenous vein, with the result that the dilated lymph-vessels subsided. A similar operation in some forms of elephantiasis of the scrotum and penis might lead to an equally successful result.

CASE 1.—A man, aged 21 years, was admitted into the German Hospital in April, 1893, suffering from soft sores and lymphadenitis in both groins. Whilst the bubo on the left side became smaller and painless, that on the right side showed signs of suppuration and had to be incised. The patient was discharged by the end of May, but was re-admitted shortly afterwards owing to the formation of a fistula on the right side; the glands of the left side had also become re-enlarged and painful. As incisions and scrapings which were undertaken several times did not effect a cure, the whole of the remaining glands (which were swollen and dotted with numerous small abscesses) with the surrounding tissues were removed by two operations in the middle of August. The operations proved lengthy and difficult, but the large vessels were not injured. Both wounds healed by granulation and the patient left the hospital in October apparently quite well. Three months later (January, 1894) he first noticed an occasional œdematous swelling of the prepuce which disappeared on applications of lead lotion. Gradually, however, the œdema recurred more frequently, extended over the penis and scrotum, and became persistent. When the patient presented himself again at the hospital in April, 1894, the scrotum was as big as two fists, the skin being hard and greatly thickened; the penis was about twice its normal size, the prepuce being especially enlarged, and the whole region was in a condition of chronic elephantiasis. In spite of different methods of treatment this condition had remained unchanged up to June, 1901, when Dr. zum Busch had an opportunity of examining the patient for the last time. Surgical interference of any kind was firmly refused.

CASE 2.—A young man, aged 20 years, was admitted into the German Hospital in March, 1896, suffering from double-sided bubo of long standing. The integument of both sides was inflamed and perforated by many fistulæ and the superficial and deep glands of the inguinal and crural regions were enlarged and fixed. Whilst the left bubo was successfully treated by numerous incisions and scrapings that on the right side showed no signs of improvement and was finally removed by an extensive operation as in Case 1. This patient remained well for about four months after his discharge from the hospital when the penis and the scrotum began to swell and gradually assumed a state of chronic elephantiasis. In this case, however, the enlargement was much more severe on the right side than on the left. When last seen, in November, 1898, the condition was rather worse than it had been two years previously.

CASE 3.—A sailor, aged 24 years, was admitted into the German Hospital in November, 1901. Dr. Lauenstein of Hamburg, under whose treatment the patient had been from August to November, 1899, has kindly informed me that the patient was operated on for double-sided bubo and that extensive operations were done on both sides, no large vessels being injured. Not very long after his discharge from the hospital the man noticed a gradually increasing œdema, first of the prepuce only, but later attacking the whole penis and the scrotum. On admission into the German Hospital the scrotum was nearly as large as a cocoanut, the penis was three or four times its normal size, whilst the prepuce hung down from the end of the penis like a balloon. In this case the lymph-stream was not entirely obstructed as by elevation in bed the size of the affected parts could be temporarily diminished; the swelling which remained was like elephantiasis in character and was exceedingly hard. As the patient was very anxious to have something done the prepuce was removed, together with a large piece of integument from the whole length of the penis. As the wound healed well and the patient was very satisfied with the result it was decided to operate in a similar way on the scrotum. Unfortunately, however, the patient developed typhoid fever and he had afterwards to be sent to a convalescent home. He is now on board ship again, but has asked for an operation to be performed on his scrotum after his return in spring.

CASE 4.—This case occurred in private practice and is illustrative of other cases. A married woman, aged 32 years, consulted Dr. zum Busch in May, 1901, and gave the following history. Three years previously she was infected by her husband and suffered from a sore in the vaginal orifice followed by suppuration of the inguinal glands. As far as one could judge from the resulting scars very extensive operations had been done in the United States. About three or four months later she developed erysipelas of the vulva which left a permanent enlargement of the labia majora. There was no fever during the erysipelatous state nor was there any marked increase of the temperature during four recurrent attacks in 1900. Each attack left the external genitals more swollen and harder. On examination in May, 1901, both labia and the clitoris were found to be very much increased in size and very hard; they, as well as the mons Veneris, were in a typical condition of elephantiasis. The patient was advised to have the labia removed by operation, but she refused.

*Remarks by* Dr. ZUM BUSCH.—This unforeseen and untoward result of the radical treatment of such cases has not been sufficiently recognised either in the text-books or in the special literature of this branch of surgery. Riedel[1] has published notes of two cases and advises surgeons to avoid too extensive operations in inflammatory conditions of the inguinal glands. Of my own numerous cases of clearing out the inguinal region in bubo and cancer I have so far only heard of two having become subject to chronic œdema and elephantiasis (Cases 1 and 2), but I should not be surprised if there were more such cases, as many of my patients probably left England after having been discharged from the hospital.

I may here add one other case in which the elephantiasis occurred in the upper extremity. The patient, a man, aged 24 years, was admitted into the German Hospital in November, 1900, suffering from chronic brawny œdema of the left upper extremity. The arm was enormously swollen and the skin was hard and in many places scaly; the condition was said to have followed an operation for suppurating axillary glands which was undertaken in France two years previously. There was a long scar in the axilla as well as a smaller one above the clavicle. Such an occurrence seems to be very rare, as I have never seen it following Halsted's operation except when the vein had to be tied or when recurrences implicated the vessels, yet it seems important to remember such cases and to be as conservative as possible in the treatment of extensive inflammatory disease of the glands. The recommendation of some surgeons to remove the whole affected area should never be followed except as a last resource in otherwise incurable cases of bubo in which a radical operation is all the more justifiable as the suppuration

---

[1] Archiv für Klinische Chirurgie, vol. xlvii.

Mr. G. R. Turner exhibited a man, aged 28 years, from whom he had removed a Sarcomatous Tumour from the Synovial Membrane of the Ankle-joint.—The President remarked that it had only recently been recognised that sarcoma arose in synovial membrane. This subject would form a topic of discussion on a future occasion.

Mr. W. G. Spencer showed a case of Appendicitis with Secondary Abscess occurring in a man, aged 38 years, in which there had been union by secondary suture of an ilio-lumbar incision after the evacuation of an abscess which had recurred for the fourth time.

Dr. J. Purves Stewart (introduced by Mr. W. G. Spencer) exhibited a case of Paralysis of the Cervical Sympathetic accompanied by photographs showing the distribution of the anidrosis. The patient, a soldier, aged about 26 years, had been wounded 14 months previously by a Mauser bullet which entered the left side of the neck one and a half inches below the mastoid process and came out in the seventh right intercostal space in the posterior axillary line, lodging in his bandolier. The bullet thus passed in front of the vertebral column. He had temporary total paralysis of the right arm which gradually cleared up. There were some hæmoptysis and slight dysphagia for a few days only. Ever since the injury the sight in the right eye had been less acute than in the left, and he had noticed that he did not sweat on the right side of the face, scalp, neck, or upper limb. As regarded the present condition, there were slight weakness of the small muscles of the right hand and an area of slight analgesia along the inner border of the upper arm, forearm, and hand, including one and a half fingers, with a small patch in the axilla. The lower limbs and the left upper extremity were normal. The right pupil was smaller than the left and did not dilate when shaded. Both pupils reacted briskly to light and on convergence The cilio-spinal reflex was absent on the right side. The right palpebral fissure was narrower than the left and the right eye was slightly sunken. He did not sweat on the right side of the face, scalp, neck, upper part of the thorax, or upper extremity. This area of anidrosis was bounded by the middle line and extended down as far as the third rib in front, and posteriorly as far as the middle of the scapula The lesion was apparently one of the first dorsal nerve-root on the right side, involving the cervical sympathetic.

Dr. H. D. Rolleston and Mr. Lawrence Jones exhibited a case of Splenic Anæmia with a Splenic Bruit, occurring in a man, aged 22 years, who had noticed a swelling in his abdomen for four years, increasing in size. There was no history of malaria or syphilis. Two years ago he had an attack of epistaxis, and since then he had repeated attacks of epistaxis, hæmatemesis, and melæna. He had considerable enlargement of the spleen. The blood showed anæmia of what is usually called the chlorotic type. There was apparently no change in the relative numbers of the varieties of leucocytes. There was a distinct blowing continuous murmur to be heard over the spleen, most distinct at the back in the ninth space, just outside the scapular line, and in front, in the ninth space, just posterior to the anterior axillary line —In the discussion which followed the general opinion was expressed that removal of the spleen constituted a rational treatment of cases of pure splenic anæmia (as distinct from leukæmia), since it resembled a chronic infective process dependent on the spleen.—Dr. Rolleston, in reply, referred to Warren's statistics, in which 20 out of 24 patients who were operated upon recovered.

Dr. S. Vere Pearson and Dr. Rolleston showed a case of Idiopathic Muscular Atrophy associated with Peculiar Pigmentation of the Legs. The patient was a man, aged 22 years, who eight years ago had scarlet fever, in the second week of which there were rheumatic pains and swellings in the knees. Weakness in the back was noticed a week later, followed by wasting of the thighs. Pigmentation of the legs had been noticed for one year. He had never taken medicine continuously for more than six weeks and he believed that he had never taken arsenic. There were now atrophy of both thighs and legs and slight foot-drop, talipes equinus, and pes cava. The muscles of the chest and spine were also wasted and there was lordosis. Although most of the muscles showed A.C.C. > K.C.C. there were no other reactions of degeneration. Sensation was normal. The skin of the legs was uniformly reddish-brown. In the discussion which followed it was suggested that the association of an amyotrophic paralysis with pigmentation having this distribution occurred in pellagra, and Dr. Ewart suggested the administration of suprarenal substance in cases of muscular atrophy.

Dr. J. A. Ormerod exhibited a woman, aged 39 years, presenting an Eruption of a Psoriasis Type but of somewhat uncertain nature.—In the discussion which followed several members expressed the view that it was of syphilitic origin, but Mr. Bowlby and others could not agree with this, and it was suggested that the case resembled mycosis fungoides in some respects; finally, this case was referred to a sub-committee for further investigation.

Dr. Ormerod also exhibited a case of Atrophic Paralysis of the Hands and Wrists supervening upon a recurrent generalised paralysis of obscure origin.

Dr. F. E. Batten exhibited five children belonging to the same family the subjects of Paralysis allied to the Myopathies and to Friedreich's Disease. The eldest was a girl, aged 15 years, who had always walked slowly and had been weak on her legs, though the calves were apparently hypertrophied. There were foot-drop and pes cavus. The knee-jerks and plantar reflexes were absent; reaction to strong faradic current was also absent. There were slight nystagmus and ataxy; the pupils reacted well. The other children presented many of the same symptoms.

Dr F. G. Penrose exhibited a case of Hydromyelia in a boy, aged six years, who presented generalised weakness and generalised loss of sensation to heat and cold.

Dr. C. H. Fennell (introduced by Dr. Archibald Garrod) exhibited a case of General Paralysis of the Insane in a girl, aged nine years. No definite history of congenital syphilis could be obtained. The child was mentally bright up to the onset of symptoms six months before.

Mr. Rickman J. Godlee and Dr. Patrick Manson exhibited two cases of Filariasis, one of which had been treated by a new operation. The younger of these, a man, aged 21 years, had not been operated upon and presented large fusiform lymphatic tumours in the groins and thighs due to filariæ. The other case was that of a man, aged 31 years, on whom Mr. Godlee had operated, producing an anastomosis between one of the dilated lymphatic vessels and a tributary of the internal saphenous vein. Subsequently another of the dilated lymphatics had been introduced into the spermatic vein. The result of these operations, which had been suggested by Dr. Manson, had been extremely successful.

## HARVEIAN SOCIETY OF LONDON.

### *Exhibition of Cases.*

A clinical evening of this society was held on Feb 20th, Mr. W. Watson Cheyne, the President, being in the chair.

Dr A. Whitfield showed a young woman the subject of Psoriasis and said that many such cases were to be seen at present in consequence of the epidemic of small-pox. The patient had suffered from psoriasis at intervals for a number of years, and the present attack came on 14 days after vaccination. The vaccination marks on the left arm were very severely affected, the right arm being more or less clear. The chest and back and knees and shins also showed the condition She was said to have had eczema since she was quite a child, and he presumed that what was thought to be eczema was really psoriasis. She was otherwise apparently in perfect health and did not complain of anything.—Mr. Campbell Williams asked whether Dr. Whitfield had tried salicin which was a favourite remedy for the condition, and he had had a good deal of success with it.—Dr. Whitfield, in reply, said that he was using creasote, which he had found to be especially useful in acute cases. He had never seen a patient benefit on salicin, though he had tried it in 50 or 60 cases. Arsenic was contra-indicated during the acute stage of the attack. He had no special theory to advance as to the connexion between the vaccination and the eruption On Feb. 18th he saw a woman, aged 35 years, with an attack of psoriasis which also came on 14 days after vaccination

Dr. A. Morison showed a boy, aged five years, who was the subject of Congenital Heart Disease. There was an abnormally placed heart, giving a considerable amount of dulness to the right side of the sternum. The second sound was felt by the hand very clearly over the præcordial region and to the right of the sternum. There was a systolic bruit, which gained in intensity towards the pulmonary area and was very loud over the front of the chest. It was also heard over the back, the flanks, and the neck. His belief was that there was pulmonary constriction.—Dr. H. A. Caley said that he thought there must be pulmonary stenosis in the case, because of the features of the bruit and of nitrogen was only about six or seven grammes without loss of weight. There could be no question as to the possibility of these men doing work, yet they only metabolised between four and seven grammes (taking the extreme limits) of nitrogen per diem. This ability to work on such an extremely low diet was apparently due to slow and thorough insalivation, which was one of the tenets of the "cult" into which they had formed themselves.—Dr. E. H. STARLING remarked that in using the expression "calories" it must be remembered that fat was included which did not play an active part in metabolism. In this sense fat simply played the part of ballast.—Dr. HALLIBURTON referred to the popular notion that Eastern nations existed on a very low nitrogenous diet; but recent analysis of Chinese dietaries showed a large aggregate of proteids in the fruits and grains. This was especially true of nuts.

Dr. S. G. HEDIN made a communication on the Proteolytic Enzymes in the Spleen of the Ox. Spleen juice pressed from the disintegrated cells of the spleen contained a proteolytic enzyme which acted very strongly in an acid medium, whilst in a neutral or alkaline medium it acted very weakly or not at all. The disintegrated and not pressed spleen-cells contained, in addition to this enzyme, another enzyme that acted upon proteids only in alkaline media. This enzyme seemed to be present in the cells in the form of a zymogen which was not soluble in water, but when exposed to the action of weak alkali or weak acid it yielded an active enzyme soluble in water. As to the purpose of the enzymes, it seemed probable that they had to carry out digestion inside the leucocytes. Intracellular digestion, according to researches mainly carried out in Metchnikoff's laboratory, appeared in most cases to be performed in an acid media, although in some instances it could be performed also in alkaline fluids.

Dr. ROBERT HUTCHISON read a paper on the conditions known respectively as Chylous Ascites and Chyliform Ascites. He stated that in the former of these conditions the opacity of the fluid was due to the presence of fat and the fluid became quite clear on agitation with potash and ether. A specimen of fluid from a case of true chylous ascites was exhibited which exactly resembled milk in appearance and contained 2·3 per cent. of fat. The patient, a man, aged 32 years, exhibited no other symptom and his blood contained no filariæ. The cause of the ascites in this case was obscure. In chyliform ascites, which had only been accurately investigated within recent years, the fluid was less opaque than in the chylous form and often had a greenish tinge. Different observers had ascribed the opalescence to (1) lecithin, (2) mucoid substances, and (3) in a smaller group to a casein-like body. The fluid exhibited was obtained from a man, aged 46 years, who suffered from chronic parenchymatous nephritis and chronic purulent peritonitis. It contained neither lecithin nor mucoid substances, but a proteid which yielded nuclein or paranuclein on digestion, and which was presumably derived from cellular disintegration. The methods of analysis employed were described in detail and a brief bibliography of the conditions was added.

Dr. H. A. SCHÖLBERG read a paper on a hitherto Undescribed Purple Pigment in Urine. This pigment was met with in a patient admitted to St. Bartholomew's Hospital suffering from Peripheral Neuritis under the care of Dr. J. A. Ormerod. The condition was probably congenital and was met with in the patient's father and in another member of the family. The pigment was not due to any drugs taken and it was differentiated from other purple pigments hitherto recognised. The means of its detection were described, and the conclusion arrived at was that it was a purple pigment allied to, though different from, the purple-coloured pigment that produced the deep colour in hæmatoporphyrinuria. When the urine was in large bulk the condition described might resemble alkaptonuria.

Dr. F. H. THIELE read a paper on a Brown Urinary Pigment. The pigment had been found in four patients admitted to University College Hospital. The first was a middle-aged woman suffering from pyorrhœa alveolaris; the second was a woman suffering from parotitis; the third was a child; and the fourth was a woman admitted for sloughing ulceration of the vagina. The pigment was precipitated from solution by ammonium sulphate, lead acetate, and alkaline baryta mixture. It was soluble in alcohol, amylic alcohol, and chloroform, and to a less extent in water. It yielded no spectroscopic band and in concentrated solutions it blotted out the spectrum from the red onwards. An alkaline solution of the pigment in caustic soda did not yield on the addition of calomel the rose-red colour obtained with urobilin. The pigment was very much like urobilin, but differed in several respects. In one case it was worth noting that the patient subsequently had a distinct urobilin band in the urine and besides having a yellowish pigmentation of the skin she had a raw surface on the abdomen the edges of which were green.

Dr. A. E GARROD remarked on the interest of both of these papers, which bore eloquent testimony to the value of the spectroscope in the recognition of biliary derivatives in the urine. Dr Scholberg's case appeared to be an individual variation in metabolism.—Dr. H. BATTY SHAW remarked on the interest attaching to the second of Dr. Thiele's cases in which the skin was certainly very yellow, but as there was no bile pigment in the urine possibly the case belonged to the condition which some writers had described as "urobilin jaundice."—Dr. HOPKINS and Dr. GARROD dissented to the use of the term "urobilin jaundice," the latter remarking that there was no evidence that the colouration of the skin was due to urobilin.—Dr. J. R. BRADFORD had seen cases at long and rare intervals in which there was yellowness of the skin, and the urine, though containing no bile pigments, contained large quantities of urobilin.—Dr. HALLIBURTON remarked on the difficulty of the spectroscopic recognition of urobilin.

## CLINICAL SOCIETY OF LONDON.

### *Exhibition of Cases.*

A MEETING of this society was held on Feb. 28th, Mr. HOWARD MARSH, the President, being in the chair.

The PRESIDENT showed a man who had sustained a Dislocation of the Semilunar Bone, the displaced bone hav been removed by operation. Skiagrams of the case w shown by Mr. Mackenzie Davidson.

Dr. GRAHAM BROWN (introduced by the PRESIDEN exhibited a new form of Æsthesiometer for estimating t degree of acuteness of tactile sense at different parts of t skin. The instrument consisted essentially of a smoot surface which could be made rough to any desired degree b means of adjustable projections from this surface. It wa specially suitable for clinical work in cases in which tactile sensation was impaired and was designed to measure the degree of loss in any given case.

Dr. WILLIAM EWART exhibited a case illustrating the Treatment of Bronchial Dilatation and Bronchial Catarrh by Posture and Respiratory Exercises. Dr. Ewart described the method, which consisted of keeping the foot of the bed raised, sometimes to a considerable height, whilst the shoulders were kept low, only the head resting on the pillow. The first case in which it occurred to him to carry out this indication had been published; others, including some cases of phthisis, had been under treatment. The method, however, had been previously thought of and described by Quincke. The patient exhibited was a man, aged 21 years, who was suffering from bronchiectasis.

Mr. JOHN R. LUNN exhibited cases of (1) Locomotor Ataxy with Disease of the Shoulder-joint in a man, aged about 65 years; (2) Polyarthritis in a man, aged 30 years; and (3) Osteitis Deformans in a man, aged 72 years (with skiagram).—In the discussion which followed reference was made to cases of osteitis deformans in which fracture had occurred, though this was thought to be unusual unless sarcoma was present.—Mr. ANTHONY A. BOWLBY, in discussing the case of polyarthritis, thought that this resembled some cases exhibited on a previous occasion by Dr. Percy Kidd in which bronchiectasis had existed. He (Mr. Bowlby) believed that there was a great deal to learn about polyarthritis, and he suggested that Mr. Lunn's case was due to some form of chronic septic infection by reason of the number of joints involved and the long duration.

Mr. CUTHBERT S. WALLACE exhibited a case of Excisi of the Lower End of the Ulna for an old Colles's Fractu The patient was a man, aged 55 years, who was admitted hospital in August, 1899, for loss of power in the hand i consequence of a Colles's fracture which he had receive some time previously. There was much abduction of th hand and flexion was extremely limited owing to the lowe end of the ulna overlapping the carpus. About three-quarters of an inch of the ulna was removed through an incision on the inner side of the wrist. Skiagrams showed the condition before and after operation. The patient could now follow his occupation.

muscular. He had seen a similar tumour mistaken for neurofibroma.

Dr. H. TILLEY showed a girl, aged 14 years, who had an Aural Exostosis with Extensive Mastoid Disease. He reflected a post-aural flap and gouged out the broad-based exostosis. The antrum was full of inspissated pus which was cleared out and the complete post-aural operation was done. The external wound was sewn up and the packing was done through the meatus. The membranous portion of the meatus was slit up and the flap was made in the usual way. The wound healed at the back by first intention. A fortnight later he reopened the wound and produced a clear surface by scraping away the granulations and putting in a large flap from the inside of the thigh, after the method introduced by Mr. Ballance. The skin graft had taken satisfactorily and the cavity was practically dry. The girl was now able to hear a whisper at a distance of four inches.

Dr. CALEY showed a case of Abdominal Aneurysm involving the aorta and the right common iliac artery. The patient was a man, aged 39 years, who had suffered from syphilis 16 years previously but who gave no history of injury or strain. With prolonged rest in bed, restricted diet, and 20 grains of iodide of potassium three times a day the pulsation much diminished in extent and in degree, the tumour became more solid, and the distension of the veins of the leg almost disappeared.—Mr. BARNARD said that a man at the London Hospital had a superior mesenteric aneurysm. The case had been twice described as an example of cure by different treatments. In the first place it was said to have been cured by gelatin treatment. Then it relapsed and was treated with anti-diphtheritic serum, and was cured under that. Now, three years afterwards, the man was in the London Hospital again, being treated with morphia, and it was suggested that the surgeon might like to resort to the ligature. But the risks of this were too great and the man would not allow a wire to be introduced into the sac.

---

# LIVERPOOL MEDICAL INSTITUTION.

*Long Duration of Pregnancy.—Gastric Ulcer.—Appendicitis running an Unusual Course.—Cerebro-spinal Rhinorrhœa.—The Relation of Mental Symptoms to Bodily Disease.*

A MEETING of this society was held on Feb. 27th, Mr. RUSHTON PARKER, the President, being in the chair.

Mr. C. THURSTAN HOLLAND read a note on the Duration of Pregnancy, based on a case—that of a young primipara—in which, counting from the last date of normal menstruation to the birth of the child the duration was 340 days, from the date of the last coitus to the birth 323 days, and from the date of the menstruation following the last coitus (an abnormal period only lasting two days) 316 days.—Dr. W. MACFIE CAMPBELL said that he had notes of 64 cases in which the date of impregnation was known, and the average came to 268 days, or rather less than is generally allowed. In one case of seduction 273 days elapsed after one coitus. Nine cases of no menstruation after marriage gave an average of 264 days, and in five cases in which the husbands (sea-faring men) were only at home for one night 277 days He never had a case similar to that of Mr. Holland, which was open to a little doubt; it was so difficult to be quite sure of the data in these matters. He had, however, notes of six cases ranging from 293 to 303 days, of three cases of 308 days, of one case of 310 days, and of one of 312 days. Mr. Holland's paper was of much interest from a professional and legal point of view, and it showed how important such a question might be.

Dr. R J. M. BUCHANAN and Mr. R. A. BICKERSTETH brought forward a case of Gastric Ulcer in which a successful operation had been performed for perforation. The patient was a female, aged 27 years, who gave a history of epigastric pain and occasional vomiting extending over a period of two years. 27 hours after the symptoms of perforation came on laparotomy was performed at the Liverpool Royal Infirmary. Much turbid fluid was found in the abdomen, collected in pockets formed by recent adhesions. A perforation near the cardiac end of the stomach was found with some difficulty, and eventually it was closed by passing a rectangular cleft palate needle deeply through the tissues on each side of it Dr. Buchanan said that on admission to the infirmary the patient did not exhibit any signs of collapse, but rather of reaction, the pulse was of good volume, 120, and steady, her temperature was 100° F., and the respirations were shallow and purely costal. Her face was pallid and somewhat pinched, the expression being indicative of pain and distress; the skin was moist. On examination of the abdomen it was seen to be much distended, the distension being localised to two areas. One, the upper, was bounded by Harrison's furrow above, and the second was a transverse furrow below, about one inch above the umbilicus. Over the epigastric distension the abdomen was tender on palpation and the wall felt somewhat boggy; it was tympanitic on percussion, and on auscultation the heart sounds were heard as if echoed in a gas-containing cavity. The liver dulness was diminished to one inch above the lower costal margin. The lower portion of the abdomen was distinctly stretched and tympanitic. The abdominal walls did not move on respiration. The patient complained of most severe pain in the left hypochondrium and extending towards the base of the left lung behind; it was intensified on deep inspiration, and auscultation revealed a soft friction-sound most marked below the diaphragm. It was not of the usual near and harsh pleuritic character and was considered to be of peritoneal origin and sub-diaphragmatic. It was impossible to locate the ulcer with accuracy, but the localised friction suggested that its position might be at the cardiac end. That such was the case was verified at the operation. Dr. Buchanan said that the points which influenced their decision for operation, even after the long period of 27 hours from perforation, were the symptoms of reaction, the steady pulse, and the rising temperature. The localised distension of the epigastrium pointed to adhesions acting as a safeguard from further leakage The operation was performed on August 6th, 1901, and the patient left the hospital on Oct. 20th, and had continued well up to the present time.

Dr. W. BLAIR BELL related a case of Appendicitis which had run an unusual course. At the operation he found an empty abscess cavity. The stump of the appendix was ligatured and was removed from the cæcum and the apex from the ileum to which it adhered and where there was a large perforation through which the abscess had discharged into the bowel. He closed the perforation and packed the abscess cavity with gauze soaked in iodoform emulsion. The patient, a girl, aged 16 years, made an uninterrupted recovery.

Mr. C. F. LARKIN read the notes of a case of Cerebro-spinal Rhinorrhœa. The fluid had escaped through a fracture of the basi-sphenoid. The patient lived for 27 days after the fracture and then died from septic meningitis.

The three last cases were discussed by Dr. C. J. MACALISTER, Dr. E T. DAVIES, Mr. F. T. PAUL, Mr. G. P. NEWBOLT, and the PRESIDENT.

Dr. NATHAN RAW read a paper on the Relation of Mental Symptoms to Bodily Disease. He first of all minutely described the symptoms present in various diseases of the viscera, with special reference to reflected visceral pains, and agreed in the main with the conclusions of Head that they were present in a fair proportion of cases of heart disease, phthisis, and diseases of the stomach and liver. He then described the various mental symptoms occurring in the course of kidney disease, gout, exophthalmic goitre, myxœdema, and chorea, mentioning several cases of temporary insanity which he had noticed. The mental symptoms occurring in the course of typhoid fever, pneumonia, and rheumatic fever he divided into two important groups, those of the initial stage of the fever due to the severity of the infection and characterised by mania and delirium and those supervening on convalesence, chiefly of a depressant and melancholic type. He had often observed post-typhoid insanity of the melancholic type with delusions, and was of the opinion that it was due to nervous exhaustion and insufficient food. In his experience post-typhoid insanity always passed off and the patient's mind was restored to the normal. He had never observed insanity to follow an attack of pneumonia. After a long observation of many thousands of cases Dr. Raw was of opinion that there was a form of temporary mental disorder which occurred as part and parcel of some bodily disease, and which rendered the patient insane for the time, but which rapidly passed away. He was strongly of opinion that these patients should not be certified as lunatics and sent to an asylum, but that they should be treated in a special hospital for mental diseases. He advocated the provision of a reception house or hospital for mental disorders in Liverpool, where patients suffering from delirium tremens and other forms of temporary mental disorder could be sent and specially treated and where the hypertrophy of the right ventricle. There was probably also an incomplete intra-ventricular septum.—Dr. E. CAUTLEY said that the case illustrated a difficult point in diagnosis. Dr. Morison had pointed out the presence of cyanosis and a murmur and had suggested the diagnosis of pulmonary stenosis. On the other hand, there was no thrill, and his own experience was that pulmonary stenosis was much more commonly diagnosed ante mortem than post mortem. The last case of the kind which he had seen was typical. The patient was a child who during life had practically no cyanosis, but had a systolic murmur which could be heard all over the cardiac area and was subsequently found to have atresia of the conus pulmonalis. The orifice was so narrowed that it would only admit a fine probe, and yet there was no cyanosis. There was, in addition, a patent septum ventriculorum. That led to the question as to the cause of cyanosis. In the child he referred to, who was four or five months old, there was extreme atresia of the conus pulmonalis; there was no obstruction in the artery, and none in the valves. It scarcely seemed probable that mixture of blood in the two ventricles could give rise to cyanosis. Therefore he asked why in the present case cyanosis was present. Was it to be ascribed to extreme pulmonary stenosis? If so, why in other cases was there no cyanosis? He, however, was not prepared to suggest any other diagnosis.—Dr MORISON, in reply, said that he thought the intermixture theory of cyanosis had been largely abandoned, obstructive conditions as the chief cause of the cyanosis holding the ground.

Mr. H. L. BARNARD showed a young woman who was the subject of Bazin's Disease and who had had the ulcers on her legs for the last five years. They appeared first as nodules under the skin and felt somewhat like erythema induratum. Those burst and broke down and formed little round ulcers each of about the size of a shilling, punched out, and extraordinarily like specific ulcers, for which they were often mistaken. They were supposed to be tuberculous, and he regarded the present patient as being tuberculous. She had had tuberculous disease of the spine and of the left ankle, the latter having got well after being put into a plaster-of-Paris case. The ulcers left a pigmented scar which looked extremely like that left by a specific ulcer. Mr. Hutchinson had pointed out that such subjects were singularly predisposed to chilblains. The present patient never had chilblains or enlarged glands in the neck. In a case similar to the present one he endeavoured to find the tubercle bacillus but failed, nor did injection of the substance into guinea-pigs and rabbits produce tuberculosis.—Mr. CAMPBELL WILLIAMS thought that there was no doubt about the diagnosis, but one point about the case was abnormal—namely, its symmetry. In his original description of the disease Bazin said that he had never seen it extend above the knee. That was obviously wrong, because it was not only seen there but might be limited to that region. Recently he saw a woman who had a patch on either knee, on the vastus internus, the lower part of the limb being free. It might occur on the hands. The present case was typical because it had ulcerated. Occasionally resolution occurred without ulceration, leaving a fawn-coloured depression. The lesions were often mistaken for tubercle, but more frequently for syphilis. Tonics, cod-liver oil, and warmth, with antiseptic dressings to keep the part clean, did much good. If the patients could go to a warmer climate they got rapidly well.—Dr. A. EDDOWES said that most of such patients had a good deal of standing, and a fair number of them were washerwomen. Another peculiarity was that the condition was worst in the winter; indeed, it occurred in some cases only in the winter.—Mr. BARNARD, in reply, said that he put the girl upon a good course of iodides and mercury, but the original ulcers got well under treatment by strapping with Scott's dressing. The last crop of lesions had got well under boric acid ointment with bandaging, combined with a tonic.

Mr. BARNARD also showed a girl with an Anomalous Condition of the Hand. She consulted him three or four months ago for what was regarded as an erysipelatous rash. Vesicles came up at night, then burst and left linear marks. The marks were upon the left hand and in a direction from right to left. The case was no doubt of artificial origin. The girl was left-handed.—Mr. CAMPBELL WILLIAMS said that the case was one of dermatitis factitia. No vesicular disease took a linear form. If the patient's hands were tied behind her back for 48 hours the rash would entirely disappear.

Dr. JAMES TAYLOR showed a woman, aged 23 years, who was the subject of Syringomyelia. Five years ago, after bathing, she had what was called a poisoned hand. Apparently there was a gathering at the base of the index finger of the left hand and that was opened. What attracted attention at that time was that although a considerable incision was made she did not seem to find it painful and was complimented by the surgeon on her pluck and composure. The wound did not readily heal. As a matter of fact there was no pluck because she did not feel the incision. Afterwards the hand was contracted and in the few years which elapsed there had been a gradual development of symptoms in the shape of weakness of the left arm, with claw hand and the vaso-motor disturbance, of which evidence could be seen. Frequently bullous sores appeared on the fingers and hand, not, so far as the patient knew, caused by any external application, but probably from hot and irritating things which she could not feel, such as burning. There was wasting of the hand and shoulder, but she said that she could walk fairly well. The knee-jerks were both of them exaggerated; ankle clonus could be elicited on both sides, as well as the extensor plantar response in the left foot. She had very marked anæsthesia to all forms of stimulation over the hand and lower part of the forearm. Higher up in the arm she had a certain degree of thermal anæsthesia and analgesia. Over the trunk there was a similar condition. On the left side of the face she had distinct thermal anæsthesia and marked analgesia on the left side of the forehead. There were marked nystagmus, which was not uncommon in such cases, and lateral curvature of the spine. Apparently until five years ago she was quite well, and Dr. Taylor thought that the condition probably depended upon some inherited peculiarity of the spinal cord which after the age of puberty took on some modification which had resulted in a spread or greater dilatation of the canal and consequent encroachment upon the anterior horn of the left side in the cervical region, and the pressure probably also resulting in some degree of sclerosis in both lateral columns.—Dr. MORISON, the PRESIDENT, Mr. BARNARD, Dr. CAUTLEY, and Dr. D. DALLAWAY took part in the discussion.—Dr. TAYLOR, in reply, said that as the patient had been under his care for only a month he did not know the rate of progression of the disease. It seemed to be extremely slow, as was usually the case. In cases of syringomyelia there were two conditions; first, a cord with a congenital abnormality which took on some slowly progressive change, probably under some condition of stress; and another kind in which it was conceivable that the whole process was one of new growth starting in the way in which new growths did, of which very little was known. He thought that Charcot's disease in such cases was rare. He had seen only one case—namely, in the elbow, which Dr. J. Hughlings Jackson and Dr. James Galloway published in THE LANCET ten years ago.[1] With regard to flushing, no doubt girls subject to the condition had the pretty pink and white complexion shown by the present patient, and he would be inclined to associate that with some vaso-motor disturbance analogous to what was present in the hands of his patient. That was all the more likely in a case in which there was definite evidence of involvement of the fifth nerve.

Dr. EDDOWES showed a man, aged 23 years, who had for nine months found a tendency for his nails to separate, but there was no other indication of disease about him. Slight influenza two years ago was the only illness that he had had for 15 years. There was no indication of psoriasis. The nails had been carefully examined for a fungus or other parasitic cause, but with a negative result.—Dr. PHILLIP said that he had never seen an exactly similar case, but a somewhat analogous condition had existed in his own person in the great toe-nails of both feet. For many years the inner three fourths died, and he had to cut that portion away. Underneath was a horny pulpy matter which he also cut away. He suffered from bad circulation, and he attributed it to that, combined with a neurotic origin. Both his hair and his nails were of very slow growth.

Dr. EDDOWES also showed a nurse who presented a Swelling in the Right Forearm which had now existed for three years and appeared to have been aggravated by sewing. Sometimes she complained of a good deal of pain and tenderness.—Dr. BOYD B. JOLL suggested that the condition might be neuroma or neuro-fibroma.—Dr. C. J. N. LONGRIDGE suggested the possibility that it was phantom tumour of the muscle.—The PRESIDENT thought that the tumour was cirrhosis of the liver in children might be explained as the result of an acute enteritis.—Dr. Taylor alluded to a case in a girl, aged 15 years, who suffered from choreiform movements associated with cirrhosis of the liver.—Dr. Weber and Dr. Sansom also discussed the specimen.—Dr. George Carpenter showed a case of Paroxysmal Hæmoglobinuria in a boy, aged three years. There was no evidence of syphilis. Application of ice-cold water to the extremities induced an immediate destructive action on the red corpuscles to the extent of 20 per cent., but failed to produce hæmoglobinuria.—Dr. Weber urged the importance of a warm climate in the management of such cases —Dr. Hawthorne, Dr. Sutherland, and Dr. Taylor discussed the case, and Dr. Carpenter replied.—Dr. Carpenter also showed a case of extreme Ichthyosis in a male infant, aged five months, which developed a few days after birth. The infant had craniotabes and chronic snuffles as well.—Dr. Carpenter also showed a boy, aged eight and a half years, with a large head, probably hydrocephalic, a supposed sequel of basic meningitis during infancy. There were rigidity of the lower extremities and a feeble gait. The enlarged head was not characteristic of hydrocephalus and was somewhat suggestive of hypertrophy of the brain.—Dr. Gwynne described the case of a boy, aged six and a half years, who was admitted to hospital suffering from obstinate constipation and great emaciation. His abdomen was enormously enlarged. As no action of the bowels could be obtained, either by medicine or by injections, left iliac colotomy was performed. The condition was diagnosed as a Congenital Dilatation of the Sigmoid Flexure of the Colon. The result of the operation was satisfactory.—Dr. J. Porter Parkinson read a paper on the Local Treatment of Adenoids. This consisted in the direct application to the naso-pharynx of an astringent compound of equal parts of solution of perchloride of iron and glycerine, applied by means of a curved brush passed behind the soft palate. Dr. Parkinson advised this treatment for soft and gelatinous adenoids which caused temporary recurrent obstruction of the nasal passages and other symptoms, such as cough, headache, aural discharges, and deafness The method was applicable to patients of any age and could be carried out with a minimum of discomfort.—Dr. Sutherland having spoken, Dr. Parkinson replied.

---

[1] THE LANCET, Feb. 20th, 189[illegible], p. [illegible].

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—An ordinary meeting of this society was held at Liverpool on Feb. 21st, Dr. S. Buckley, the President, being in the chair.—Dr. T. Arthur Helme (Manchester) showed the following specimens. 1. A Carcinoma of the Cervix Uteri with Double Pyosalpinx removed per vaginam from a nullipara, aged 23 years. The patient had been married 12 months. The husband had gonorrhœa a few months before marriage. The symptoms of menorrhagia and discharge had existed for about six months The points of interest in the case were the early age for cervical cancer, its occurrence in a nullipara, and the association with gonorrhœal pyosalpinx. The growth consisted of columnar carcinoma. 2 A Polypoid Carcinoma of the Corpus Uteri removed by vaginal hysterectomy from a virgin, aged 41 years. The operation was rendered difficult by the smallness of the vagina, and incision of the perineum was required and also median incision of the anterior uterine wall. The ligaments were clamped. The growth was adeno-carcinoma It originated in the right side of the body of the uterus, forming a large polypoid mass protruding into the vagina 3 A Solid Ovarian Tumour and Primary (?) Tuberculous Peritonitis with Ascites. Wasting, ill-health, and abdominal enlargement had been noticed for some months previously. There was an evening rise of temperature which was subnormal in the morning. The signs were those of a considerable amount of free fluid in the peritoneal cavity, together with the presence of a solid ovoid tumour in the right ovarian region. The uterus was not enlarged. The history, general condition, and physical signs suggested tuberculous peritonitis rather than simple ascites associated with the tumour. The abdomen was opened and the tumour was removed. It was a fibroma of the right ovary. There was no evidence of malignancy. The whole of the posterior surface of the right broad ligament and uterus was covered with a thick caseous tuberculous-looking material and the pelvic peritoneum generally showed the usual evidences of tuberculous peritonitis. Both Fallopian tubes appeared to be healthy. The ascitic fluid was removed and the abdomen was closed. The patient had completely recovered health at the present date, nine months after operation.—The specimens were discussed by Dr. E T. Davies and others.—Dr. Lloyd Roberts (Manchester) showed a large Uterine Polypus removed from a married woman, aged 52 years. There was commencing necrosis with offensive discharge and bleeding. The pedicle, which was of about twice the thickness of a thumb, sprang from the posterior uterine wall above the internal os. In addition to the polypus the posterior cervical lip and adjoining vaginal fornix showed superficial ulceration. The appearance of the polypus suggested the possibility of malignancy, but examination failed to reveal such a condition. A further investigation would be made —Dr. W. Walter (Manchester) showed a Solid Tumour of the Right Ovary removed by abdominal section from a multipara, aged 39 years, whose periods suddenly ceased five years previously. The other ovary was small and atrophied and no ascites was present. At the outer end of the tumour, which was of the size of a small cocoanut, the capsule was very thin and friable, and over a small area the contents were pink and of the consistence of putty. The remainder of the tumour was firm and cut like a pear. Some parts looked like a fibroma, but microscopically the ovarian stroma was found to be extensively infiltrated with round-celled sarcoma —Dr. H. Briggs (Liverpool), Dr. A. Donald (Manchester), and the President discussed the difficulty of distinguishing benign from malignant connective-tissue tumours of the ovary, and Dr Walter replied.—Dr. Donald and Dr. W. K. Walls related a case of Spontaneous Rupture of a Uterus Bicornis Unicellis during Pregnancy. The first four confinements had been tedious or instrumental. The fifth occurred in St. Mary's Hospital, Manchester, and was described by Dr. Walls in the society's *Transactions* for 1899. The present labour commenced with pain and hæmorrhage and the placental edge was felt just within the cervix. The cervix was plugged, but as bleeding returned and pains ceased a leg was brought down under chloroform. The skin of the fœtus was peeling. No progress taking place multiple incisions of the cervix were made and the base of the skull was perforated. The cervix tore, the laceration involving the broad ligament through the peritoneum. On passing the hand to remove the placenta the two horns were found to have separated, the thin intervening tissue having given way. The abdomen was opened and pan-hysterectomy was done. The patient made a good recovery.—Dr. Briggs exhibited: (1) three examples of Solid Ovarian Carcinomata; (2) Necrobiosis of Fibroma of the Ovary; (3) Double Ovarian Cystoma and Pregnancy; and (4) Vaginal Nodules in a case of Adeno-Carcinoma of the Cervix —Remarks were made by Dr. Donald, Dr. Lloyd Roberts, Dr. Walter, Dr. N. Raw, and Dr. Helme, and Dr. Briggs replied.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 28th, Dr. A. G. Barrs, the President, being in the chair.—Mr. T. Pridgin Teale read a note on the Relief of a Distended Joint by the Establishment of Subcutaneous Leakage. The first case on which this practice was based was one of acute distension of the knee-joint attended by intense pain which he had punctured with a narrow knife expecting to find pus. As the fluid which escaped along the knife-blade was but slightly turbid synovial fluid, instead of opening and draining the joint externally he made three or four punctures with the narrow knife, taking care that the openings into the synovial cavity should be about half an inch in extent. The result was that the fluid escaped from the joint into the tissues outside the joint and was there harmlessly absorbed. There was at once relief to pain and the joint rapidly recovered. Mr. Teale had adopted the same method on several occasions. Mr. J. Hardie of Manchester had written to Mr. Teale that he had adopted this plan several times with relief in early disease of the hip-joint, but had not continued to use it as he became convinced that most of the cases to which it was applicable needed early excision, inasmuch as the disease in the majority of cases began in the subchondral layer of bone and then affected the synovial membrane.—Mr. H. Littlewood and the President took part in the discussion.—Dr. A. L Whitehead read a paper on the Influence of Nasal and Naso-pharyngeal Obstruction upon the Development of the Teeth and Palate. The conditions giving rise to such obstruction were enumerated and the changes brought about in the shape of the palate and the position of the facilities could be given to students for studying this important group of mental disorders; and he was of opinion that such patients should not be subject to the stigma of having been certified as lunatics when a few weeks of special care would restore the mental equilibrium.—Dr. W. B. WARRINGTON mentioned the important observations of Sherrington who found that the emotional life of dogs seemed to be unimpaired after a complete section of the spinal cord below the origin of the phrenic nerves, and also in addition section of one vagus nerve. He also alluded to the innumerable poisons which could be demonstrated in the nerve-cells, and expressed the opinion that these changes had no distinguishing features from one another. He considered that the characteristics of mental disorder in visceral lesions depended rather upon the psychical life of the individual.—Dr. T. R GLYNN, Dr. W. CARTER, Dr. F. A. GILL, Mr. C. T. STREET, and Dr. J. BARR spoke, and Dr. RAW replied.

---

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### SECTION OF PATHOLOGY.

*Fractures of the Radius and Femur.—Cultivation of the Tubercle Bacillus.—Exhibition of Specimens.*

A MEETING of this section was held on Feb. 21st, Professor E. J. McWEENEY, the President, being in the chair.

Professor E. H. BENNETT presented a cast and a skiagram of a Fracture of the Lower End of the Radius with Displacement of the Lower Fragment Forwards (reversed Colles's fracture, Smith's fracture), and described the details of the injury which had occurred six months before its examination by him; he also discussed the treatment. He then recorded the history of a case of impacted intra-capsular fracture of the neck of the thigh-bone, and presented to the Academy a skiagram which showed very fully the details of the bone lesion—a fracture in which the lower fragment was driven into the upper, and so by the impaction the pieces were fixed in apposition. All surgeons, he said, were now agreed that the non-union of non-impacted intra-capsular fractures was due to want of contact of the fragments and want of rest of the part. In all the specimens which he had seen the lower fragment was impacted in the upper.—Dr. J. KNOTT discussed the case.

The PRESIDENT (the chair being temporarily occupied by Professor BENNETT) demonstrated a case of Tuberculous Pleuro-pericarditis in which the bacilli were unusually numerous, so that cultures made direct on Löffler's serum gave abundant growths of the tubercle bacillus. He exhibited these primary cultures, showing the lichenoid appearance of the colonies and their characteristic tendency to grow on to the glass. Secondary cultures on glycerinated potato were also shown. They were most luxuriant, of a light reddish hue, nd the bacilli formed a scum on the dilute glycerine. He lso exhibited tertiary cultures on glycerine agar which were cceeding well. On this medium the colonies were whitish e patient was a man, 55 years of age, who suffered from erculous pleurisy on the left side. In the right lung there were nodules of tuberculous broncho-pneumonia, but the pleura was free. The superior pericardial glands were tuberculous, and the parietal layer of the pericardium was much thickened and infiltrated with caseous matter. The spleen was enlarged so as to form a tumour readily palpable during life. It was studded with yellowish necrotic masses larger than miliary tubercles and containing tubercle bacilli in large numbers. In the affected parts of the pericardium the bacilli formed masses large enough to be seen with the low power in the stained preparation.

The SECRETARY read (for Dr. D. F. RAMBAUT) a description of a Case of Congenital Hydronephrosis. The patient was a male who died from pulmonary phthisis. He had shown no symptoms or signs of kidney disease and his urine was free from albumin. The right kidney, which showed the hydronephrotic change, appeared a little larger than the left and weighed five and a half ounces, or half an ounce more than the left. Its capsule was non-adherent, and its cortex appeared normal. Much absorption of the pyramids had taken place. The ureter was not dilated The left kidney, the bladder, the prostate, and the urethra appeared normal.—The PRESIDENT said that he considered the specimen to be a case of dilatation of the pelvis and calyces of the kidney rather than one of hydronephrosis.

Dr. W. J. THOMPSON read a paper on a Large Abdominal Cyst. The patient was a mechanical engineer, 36 years of age, and was admitted into Jervis-street Hospital on Oct. 9th, 1901. On admission he was thin and emaciated, weighing 10 stones. The upper part of the abdomen was greatly distended. In May, 1900, he first noticed a swelling in the region of the liver and this gradually increased until it attained its present size. He lost flesh rapidly, and shortly before his death, which took place on Dec. 13th, he only weighed eight stones and four pounds. He was frequently urged to allow an operation, but would never consent. The diagnosis arrived at was that it was a huge cyst, and that it was either in connexion with the pancreas or the omentum, or that it was situated in the lesser sac of the peritoneum. At the necropsy a great number of adhesions were found but there was no ascitic fluid. The cyst was very moveable and had the stomach stretched over and adherent to the anterior surface. The pancreas and descending aorta were embedded in its walls. Its circumference measured 32 inches. All the other abdominal organs seemed healthy and there were no enlarged glands.—The PRESIDENT said that the specimen was a good illustration of the rapid growth to an enormous size that pancreatic tumours, or tumours connected with the pancreas, might attain to.

---

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—An ordinary meeting of this society was held on Feb. 21st, Dr. James Taylor being in the chair.—Mr. J. Jackson Clarke showed a girl, aged nine years, who sustained a Fracture of the Outer Condyle of the Humerus in August, 1901. When seen two weeks after the injury the elbow was rigidly extended, the ulna was dislocated backwards, and the bones of the forearm were dislocated outwards. Under chloroform the elbow-joint was fixed at a right angle. There was now perfect power of pronation and supination, as well as an increasing degree of flexion and extension.—The case was discussed by Mr. Alfred H. Tubby.—Dr. C. O. Hawthorne showed a case of Congenital Spastic Paraplegia in a boy, aged two and three-quarter years. There were crossed-leg progression and heightened tendon phenomena, but no positive evidences of a cerebral lesion. There was no specific disease or family neurosis.—Mr. H. L. Carre-Smith inquired as to the results of ophthalmoscopical examination —Mr. Tubby was of opinion that the subjects of this affection were never mentally complete.—Dr. G. A. Sutherland regarded the slight strabismus present in the case as confirmatory of a cerebral origin.—Dr. Robert Hutchison was inclined to regard the case as one of Little's disease.—Dr. Taylor thought that syphilis undoubtedly played a part in the causation of the disease, for he had seen some patients with syphilitic choroiditis —Dr. Hawthorne, in reply, said that the fundus showed no changes and that the family history was not suggestive of syphilis.—Dr. Hawthorne also showed a case of Hypertrophy affecting the right lower limb of a boy. The condition seemed to affect the bones as well as the soft tissues. The tibial arteries were probably enlarged. Hæmorrhagic spots and patches were present on the leg and on the dorsum of the foot. There was no other deformity except a moderate degree of hypospadias.—Dr. A. L. Sansom believed that this was an instance of genuine hypertrophy.—Dr F Parkes Weber thought that the spots and patches were distinctly nævoid. The veins and arteries of the limb were much dilated.—Dr. Hawthorne replied.—Mr. Sydney Stephenson showed a girl, aged 11 years, with a Congenital Paralysis of the Oculo-motor Nerve on the Right Side. After discussing the theories of causation he concluded that the condition was due to an absence of, or to functional inactivity of, the nuclei of origin of the nerve.—Dr. Taylor, after mentioning the rarity of such cases, said that he did not know whether any definite lesion had yet been found in the nerve nucleus.—Mr. Carre-Smith asked if there was any evidence of congenital syphilis.—Mr. Stephenson, in reply, stated that there was neither family nor personal evidence of syphilis.—Mr. E. W. Goble exhibited a specimen showing Perforation of a Tuberculous Ulcer of the Small Intestine in a boy, aged six years. The child died from general tuberculosis —Dr. C. N. Gwynne (Sheffield) remarked that tuberculous nodules in the intestines sometimes existed without causing any symptoms. He had met with such nodules when operating for the radical cure of hernia in children.—Dr. W. C. Chaffey (Brighton) exhibited a specimen of Cirrhosis of the Liver from a girl, aged 10 years. —Dr. W. T. Lister thought that some obscure cases of and diagnosis by Dr. F. W. Eurich, and its treatment and complications by Dr. H. J. Campbell.—Dr. Evans said that in Bradford during the years 1897 to 1900 cases arose in 934 houses; of these houses 737 were furnished with midden closets and the remainder with water-closets or "tipplers." He exhibited a Pettenkofer's chart for the town of Munich in which the height of the subsoil water and the prevalence of typhoid fever were represented. He expressed the opinion that Pettenkofer's theory was not proved, but that the diminution of typhoid fever in Munich was due to the general improvement in the sanitary conditions of the place.—Dr. Eurich dealt with the bacteriological diagnosis of typhoid fever. After describing the characters of the bacillus typhosus, cultural and morphological, he concluded that the direct bacteriological test was impracticable for diagnostic purposes. He alluded to the direct examination of the splenic blood obtained by aspiration and condemned it as dangerous and uncertain. Widal's test was described, but it was pointed out that trustworthy results could be obtained only if a proper proportion of serum to bouillon culture were present. This proportion was stated to be about 1 to 40.—Dr. Campbell, speaking of treatment, said that up to the present no very satisfactory result had been obtained from treatment by antitoxic sera. In regard to the treatment by drugs, they were to be divided into three classes: (1) intestinal antiseptics; (2) cardiac and respiratory stimulants; and (3) antipyretics. He condemned the use of antipyretics except on very rare occasions. The second class of drugs must be used in general indications. He considered that strychnine should be used only in large doses and for a short time in cases of collapse. Digitalis might be useful in small doses, both for its diuretic effect and also for its action on the heart muscle. He thought that alcohol would be required in most cases, but should not be given as a routine practice. Cases treated systematically by baths showed a lower percentage mortality than others, but the bath treatment could only be carried out satisfactorily in hospitals, or at any rate where plenty of assistants were available. In regard to diet a decided opinion was expressed in favour of milk as the staple diet for typhoid fever patients.—Dr. Dunn related some of his experiences with the troops in South Africa. He said that in 30 per cent. of the cases there was no eruption of the skin. Milk was not usually available, except sweetened condensed milk which the men disliked. They had pulped bread, thin bread-and-butter, and beef-tea In 10 days or less from the time that the temperature was normal the men often had to shift pretty much for themselves and were fed on ordinary diet of bread or biscuit, jam, and corned beef. He said that relapses were infrequent and deaths from perforation were uncommon.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 19th, Dr. E. C. Kingdon, the President, being in the chair.—Dr. C. B Taylor showed two cases of Recent Extraction for Double Cataract.—Dr. H. Poole Berry read a paper on the Importance of the Attempt at the Diagnosis of Common Functional Disorders—The President, Dr. W. B Ransom, Mr. T. Geraty, Dr. F. H. Jacob, and Miss S. Gray discussed the subject, and Dr. Berry replied.—Dr. Jacob read a short paper on the Diagnosis and Treatment of Empyema. Bronchiectasis at the base of the lung, subphrenic abscess, and pyopericardium might be mistaken for empyema, and withdrawal of pus by means of a needle of large calibre was necessary for diagnosis; examination of pus was valuable—thick creamy pus showing pneumococci, thin pus streptococci, and putrid pus the possibility of subphrenic abscess. As regards *treatment*, aspiration alone was not trustworthy, though it was sufficient in some cases; removal of a piece of the ninth rib just outside the angle of the scapula and free drainage he had found most successful. Tuberculous cases never did well if opened and drained, as they became infected by other organisms and death was thereby hastened. The value of treatment by means of irrigation and baths of a weak solution of boric acid were instanced; also Estlander's operation in chronic cases—The subject was discussed by the President, Dr. Ransom, Dr. W. E Tresidder, and Mr. R. G. Hogarth, and Dr. Jacob replied.

HEALTH OF BUDLEIGH SALTERTON.—Mr. C. Beesley, the medical officer of health of Budleigh Salterton, states that during 1901, on an estimated population of 1883. the death-rate was equal to 18 per 1000, but more than half of these deaths occurred in persons over 65 years of age. The birth-rate was extremely low, being 12 2 per 1000.

# Reviews and Notices of Books.

*Lessons on Diseases of the Nervous System, 1898–99.* By Professor F. RAYMOND of the Salpêtrière Hospital, Paris. Fifth Series. Paris: Octave Doin. 678 pages. Price 16 francs.

THIS volume, which is accompanied by some coloured plates illustrative of various degrees of changes of sensibility with regard to heat, cold, and touch, shows the same degree of analytical subtlety in diagnosis and of general acquaintance with the views of authorities on the various subjects that we noted in a review of the fourth series of lectures [1]

There are 32 discourses, of which eight are devoted to the question of epilepsy in its sensory and psychical relations, and there are some chapters describing modifications of insular sclerosis, hysterical deafness for words, cases of scleroderma, troubles of sensibility in syringomyelia and insular sclerosis, and two examples of amyotrophic lateral sclerosis. In Chapter VI. there is an interesting and comprehensive *résumé* of our knowledge concerning the topography of the cortical centres for general sensibility, from which it seems that whilst the doctrine of motor localisations in the area of the Rolandic zone appears to be impregnable, the same cannot be said of the centres for general sensibility. Discussing the method of Flechsig the author says that the Rolandic zone is the first territory of grey matter which enters into centripetal connexion with the periphery. Towards the end of intra-uterine life a second system of sensory fibres connects the optic thalamus with the convolution of the corpus callosum. After birth a third system of sensory fibres spreads out in the three frontal convolutions and in that of the corpus callosum, but especially in the foot of the third frontal convolution. The tactile sphere of Flechsig must not be confounded with that of general sensibility which occupies an area greater than the Rolandic but the precise limits of which we do not yet know.

One of the most interesting chapters is on three cases of scleroderma. Professor Raymond says that though at first sight this affection would appear to belong exclusively to dermatology, yet when viewed fundamentally it betrays its neuropathic origin, resembling the tropho-neuroses. The proof of this position is furnished by the nature of the pre-sclerodermic manifestations and by the order of distribution of the foci of thickening which are often symmetrical, or placed along the course of a nerve, or segmentary as if from a lesion of the radicles of a spinal nerve Again, scleroderma is generally found in people whose personal or family antecedents show a predisposition to nervous affections, and it is also associated with other affections of a neuropathic character—e g., hemiatrophy of the face, a complaint which often results from a central trophic neurosis. It may also be associated with exophthalmic goitre, or with tabes or infantile paralysis. There is, however, one capital objection to make against this view of the origin of scleroderma—viz., that up to the present time not any constant material alterations have been found in the nervous system, and nothing has been detected in the seat of the cutaneous alterations, in the great sympathetic, in the spinal ganglia, or in the roots of the nerves. The conclusion arrived at is that although it is a disease of the nervous system, yet its true nature and seat are not settled. Quite recently Leredde and Thomas have maintained that the lesions of the skin in the slow and extensive form of scleroderma are due to a toxic agency, but this is merely a theory, and Professor Raymond prefers to believe that a trophic neurosis is more acceptable

Chapter XXXII. is devoted to a very complete and teeth were described in detail.—Dr. A. Bronner, Mr. W. E. Margetson, Dr. J. E. Eddison, Mr. Teale, and the President took part in the discussion.—Dr. J. Gordon Sharp read a paper on Some Points in the Action of Digitalis and Strophanthus. He said that of the preparations of digitalis the tincture was the best because it contained a portion of all the active principles. The infusion was not so useful because it contained practically only one active glucoside. The old belief that the tincture did not keep was fallacious, for Dr Sharp obtained a tincture in the ordinary way of trade and found it physiologically active at the end of 14 months The active principles, such as digitoxin, digitalin, and digitalein, were not so trustworthy as the tincture or dried leaf in pill form. One advantage of the tincture or dried leaf over an isolated active principle was the combination of active principles whereby overaction was obviated, one active agent neutralising another to a large extent. The slowing of the pulse-rate in the patient taking digitalis was discussed, and it was ascribed to the heart being able to do more work in a given time; hence there was not the need for the heart to beat so fast, and what was lost in number was more than made up in increased contraction force. Within certain limits the nitrites and similar bodies were antidotal to digitalis, and the reverse held good, but it had to be remembered that there was a "difference in time" action, as, for example, sweet spirits of nitre in attaining its maximum action was 96 times more active than digitalis. In ordinary doses he believed that the drug was mainly excreted by the kidneys, and by treating large volumes of the urine of a patient taking digitalis with alcoholised chloroform he was able to obtain an extract which reacted similarly to extract of digitalis, and the same extract when perfused through the blood-vessels of a frog produced contraction and this contraction could be undone by subsequent perfusion of sodium nitrite. Coming to strophanthus, he said that the drug was not so poisonous as was supposed when given by the mouth because it was perhaps rapidly excreted by the kidneys. A woman had been known to take one fluid ounce of the tincture in 24 hours without being any the worse. In its action the drug was not like digitalis Any action which it had on the heart was that of a heart poison pure and simple, and any diuretic action it had was that of an irritant to the kidneys. Dr. Sharp believed that strophanthus would in time disappear from the present list of cardiac tonics.—Dr. C. M. Chadwick, Dr. Eddison, Dr D Sanderson Long, and Dr. Liddell joined in the discussion.—Dr. Bronner showed Picsbergen's Massage Vibration for the Treatment of Some Diseases of the Eyeball. —Dr Maule Smith showed a specimen of Tuberculosis of the Kidney of a Cow.—Other specimens were shown by Dr E Ward, Dr. J. Allan, Mr. W. Thompson, Mr. H. R. Beale, Mr. S. Walker, Mr Whitehead, Mr. W. H. Brown, Dr. T. W. Griffith, Mr. A W. Mayo Robson, Dr. J. B. Hellier, Mr. B. G. A. Moynihan, and Mr. L. Knaggs.

---

[1] THE LANCET, Feb. 22nd, 1902, p 525.

**WINDSOR AND DISTRICT MEDICAL SOCIETY.**—The fifth meeting of the session of this society was held on Feb. 26th, Mr. W. B Holderness, the President, being in the chair.—Dr. H. Sinigar of Leavesden Asylum showed microscopical preparations of Typhoid Bacilli, Diphtheritic Membrane, Pneumococci, Leprosy and Plague Bacilli, Staphylococci, and the Bacilli of Anthrax.—Dr. E B. Hulbert showed, by permission of Mr. J. R. Lunn, specimens of Desquamated Skin from cases of Epidemic Eczema (Savill's disease).—Mr. T. H. E Meggs showed photographs of a case of Small-pox which had been recently under his care. The patient was 14½ years of age and had been vaccinated unsuccessfully when a baby She was again vaccinated five years ago when only one place took.—Dr. G. E. Hale showed a case of Retinitis Pigmentosa. Though not a deaf mute the patient had been very deaf for years. There was considerable limitation of the field of vision, but in spite of this the patient was a good shot.—Dr. C. R. Elgood showed a case of Successful Vaccination in a woman who had had Small-pox.—Dr Sinigar read a paper, entitled, "Results of the Vaccination of 1050 Adults." These results showed the number of vesicles that ensued in the case of primary vaccinations in the case of those once vaccinated, of those twice or three times vaccinated, and in the case of those who had had small-pox. The percentage of successes was recorded and all failures and doubtful results were duly noted. At the outset stress was laid on the want of uniformity in the potency of the different strains of lymph on the market. The paper then dealt more particularly with the clinical aspect of revaccination. Most of the cases presented very little constitutional disturbance and the vesicles ran a perfectly normal course, but in a certain proportion of cases the following were noted: papules from dressing irritation in 24 cases, pustules spreading beyond the vaccinated area in six cases, boils in 21 cases, carbuncle in one case, abscesses in four cases, reappearance of old skin trouble in one case, eczema in three cases, herpes in one case, erythemas in 23 cases, auto-inoculation in five cases, and generalised vaccinia in one case. The high percentage of successes among patients who had previously had sma pox was noted and conclusions were drawn. After describin a staphylococcus which had been grown from the lymp used, the paper concluded with an expression of the hope that the specific agent of vaccinia might soon be discovered, so that a standardised lymph and one free from extraneous organisms might then be used.—Dr. E. S. Norris (Eton) read a paper entitled, "1000 Cases of Vaccination and Revaccination" The paper commenced with an account of the small-pox epidemic of 1876-77, as witnessed by Dr. Norris at the Homerton Fever Hospital. The conclusions arrived at as to the effects of vaccination and revaccination were in the main that neither operation prevented an attack of small-pox in every case, though each did so in very many cases. Tables were next given showing the incidence of small-pox in the vaccinated and unvaccinated respectively, the general agreement of the experience of Dr Norris with that of other observers being especially shown in the heavy mortality among unvaccinated infants The value of good marks as distinguished from bad ones was next dealt with, this value being much more manifest after puberty, for in very early life it would appear that almost any kind of vaccination might suffice to obviate the worst effects of small-pox. The question whether vaccinia and variola could run their course together was gone into, several cases of interest being quoted. The paper ended with an allusion to the very high protective influence exerted by revaccination—a fact admitted by all observers.—Mr. J Brickwell, Mr. J. H. Tomlinson, Mr. T. H. E. Meggs, Dr. Hale, Dr W. A. Ellison, Mr. E. W. Adams, and the President spoke on the subject matter of the papers, and the discussion, on the motion of Dr. Ellison, was adjourned to the next meeting.

**DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.**—A meeting of this society was held on Feb. 26th, Dr A. J. Harrison, the President, being in the chair.—The President announced that Dr. Unna of Hamburg had most kindly accepted the invitation of the council to give the oration at the annual meeting on May 22nd.—Dr. J. H. Stowers then showed (1) a case of Lichen Planus; (2) a boy with extensive Alopecia and severe Vesicating Erythema of the Hands; and (3) a girl suffering from Favus. The last patient was born, and had lived all her life, in London. The origin of the condition could not be traced. Microscopical preparations of the fungus were exhibited.—Mr. George Pernet showed a case of Trophic Disorder of the Nails. He sought for an explanation of the disorder in some toxæmic state induced by carious teeth.—Dr. Alfred Eddowes showed a case of Calcification of Follicular Plugs found in Acne-like Papules on the Legs. The man, a painter, aged 70 years, had tophi on both ears and this led the members present to consider the salt found to be urate of soda. Microscopical sections of a papule were shown.—Dr. E. G. Graham Little showed the following cases: 1. Keratoderma Symmetrica of six months' duration in a woman. Dr. Little would not definitely exclude syphilis, but he believed the case not to be syphilitic. He suggested the possibility of arsenic, taken in beer, as a cause. He drew attention to the fact that the disease was preceded by tingling of the legs. 2. Lupus Vulgaris in a little girl, one of whose eyes had been completely destroyed by old phlyctenular ulceration. 3. Lichen Scrofulosorum in a boy.—Mr. Arthur Shillitoe showed (1) a case of Extensive Gummatous Infiltration of the Thoracic Wall in a man who contracted syphilis 30 years ago and had never since been free from som manifestation of the disease; and (2) a case of Genera Scaling Papular Syphilide.—Dr. Wilfrid B Warde showed (1) a case of Lupus Erythematosus; and (2) a case of Erythema Induratum

**BRADFORD MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on Feb. 10th, Dr. H. Honeyburne being in the chair.—A general discussion was held on Typhoid Fever, the public health aspect of the disease being introduced by Dr. Arnold Evans, its pathology sterilised milk giving absolutely no evidence to the taste of having undergone a sterilising process.

### LECITHINE PREPARATIONS (CLIN) AND THE CACODYLATES (CLIN).

(F. COMAR AND SON, 64, HOLBORN-VIADUCT, LONDON, E.C.)

It is well known that lecithine is a phosphorised organic constituent found in nervous tissues, in egg yelk, and in the soft roe of fishes, while it is undoubtedly one of the phosphorised principles of the brain. It is a glycero-phosphoric acid in which two stearyl groups replace two hydroxyls, and distearyl-glycero-phosphoric acid combined with choline is lecithine, a yellowish-white, waxy solid, yielding on decomposition glycero-phosphoric acid, stearic acid, and choline. Lecithine has a very favourable influence on metabolism. It is a natural glycero-phosphate and is stated to increase the appetite and to effect a notable augmentation of weight in patients suffering from tuberculosis or anæmia. M. Lancereaux regards it as an excellent food, rendering great service in cases of rapid denutrition. In the preparations before us, consisting of pills of pure lecithine, granulated lecithine, and solution of lecithine, the lecithine was extracted from eggs by a carefully conducted process. The pills contain each 0·05 gramme of lecithine. The same quantity is contained in a teaspoonful of the granular preparation and the same quantity again in the hypodermic solution. The use of lecithine would appear to be a distinct advance therapeutically on the administration of chemically prepared glycero-phosphates. From the same firm we have received specimens of cacodylate preparations (Clin). The preparation of iron called "marsyle Clin" is worthy of notice in particular. It is a true compound of ferrous iron with cacodylic acid. It is reported to have given excellent results in those pathological conditions, such as anæmia or chlorosis, for which the use of iron or arsenic, or both, is indicated. The globules of marsyle are so made as to pass through the stomach without being dissolved, so that the garlic odour and taste occurring in eructations are said to be avoided. This interesting compound of arsenic and of iron, the former an adjunct to the latter, may also be had in the form of "drops" or in solution for injection. These Clin preparations are of distinct therapeutic merit.

### SCOTCH WHISKY, THE ALL MALT BRAND (A.M.B). No. 1 AND No. 2.

(P. MACKENZIE AND CO., LIMITED, 69, SOUTH JOHN-STREET, LIVERPOOL.)

On analysis the two samples of whisky submitted to us, each representing a separate vat, presented similar characteristics, as the following figures show. Whisky from vat No. 1: alcohol, by weight 43·14 per cent., by volume 50·72 per cent., equal to proof spirit 88·88 per cent.; extractives, 0·15 per cent.; acidity, recorded as acetic acid, 0·03 per cent. Whisky from vat No. 2: alcohol, by weight 43·71 per cent., by volume 51·32 per cent., equal to proof spirit 89·59 per cent.; extractives, 0·13 per cent.; acidity, recorded as acetic acid, 0·03 per cent. Each whisky possessed a pale colour which is consistent with the low amount of extractives shown in the above analysis. The degree of acidity was so slight as to be negligible. It is stated that this whisky is a pure malt whisky, and there is nothing in these analyses to show the contrary. Moreover, both whiskies possessed a delicate flavour which was decidedly malty, while they are soft rather than harsh to the palate, from which it may be deduced that both also have been duly matured.

### SPARKLING MOSELLE NATURAL BRUT.

(M. EISENHARDT AND CO., 20, CLIFFORD-STREET, BOND-STREET, LONDON, W.)

This wine is for all practical purposes sugar-free. Though it shows a reducing action on alkaline copper solution this is comparatively trifling and not entirely due to sugar. safely be stated that the sugar is decidedly less than one-fifth per cent. That there are just traces of sugar present is evident from the fact that we obtained characteristic crystals of glucosazone on treating the wine with phenyl-hydrazine in the usual way. Further results of analysis were as follows: alcohol, by weight 10·92 per cent.; by volume 13·52 per cent., equal to proof spirit, 20·30 per cent.; extractives, 1·78 per cent.; mineral matter, 0·15 per cent.; volatile acid recorded as acetic acid, 0·01 per cent.; non-volatile acid recorded as tartaric acid, 0·36 per cent. The wine possesses a delicate flavour and it is attractive and agreeably sparkling. We have very seldom examined a sparkling wine so free from sugar as this is, and it may therefore be recommended to those who are forbidden sugar-containing wines.

### WAND'S PILLS, PERLES, CAPSULES, AND TABLETS.

(MR. S. WAND, HAYMARKET, LEICESTER.)

We have received types of the products of this firm illustrating the improvements which the latest machinery effects in regard to the making of pills, capsules, perles, &c. We have put some of these to the test and find that the contents are as described, while each particular form of medicament yields readily to the dissolving action of water or dilute acids or alkalies. The gelatin-coated pills and granules, oval in shape, are perhaps worthy of special remark. They keep well, are soft, and are readily swallowed; they are said to be free from pinholes—a statement certainly true of the specimens sent to us. The specimens included phenacetin tablets, compound sulphur tablets, capsules, oval gelatin-coated pills, and pearl-coated pills containing the Blaud iron mass, and varnished aperient pills and santal perles.

### (1) ALGINOID OF IRON; AND (2) THYROGLANDIN.

(EVANS, LESCHER, AND WEBB, 60, BARTHOLOMEW-CLOSE, LONDON, E.C.)

Alginoid of iron is a compound of alginic acid and iron, the former being derived from the gelatinous substance prepared from algæ. Alginic acid appears to form definite metallic salts; that of iron is known as ferric alginate and contains 10·97 per cent. of iron. It is said to be unaffected by the gastric digestion and to pass the stomach unchanged and to be without astringent effect on the bowels, and is laxative rather than constipating. This curious iron compound may be obtained in the form of pills, pellets, or powder and has been administered, it is said, with good results in anæmia and chlorosis. Thyroglandin occurs in the form of powder, which is said to contain all the active principles of the thyroid gland of the sheep and to be four times the strength of the fresh gland. It is prepared under a patented process and is said to be of uniform strength and quality.

### HOVIS FOOD FOR INFANTS AND INVALIDS (No. 1 AND No. 2).

(HOVIS BREAD FLOUR CO., LIMITED, MACCLESFIELD.)

The advantages of these foods are that they are almost entirely soluble and that by the addition of them to diluted cow's milk a milk is obtained presenting the same composition as human milk. The method of their preparation necessarily involves their sterilisation. The composition of Food No. 1, according to our analysis, was as follows: moisture, 3·25 per cent.; mineral matter, 1·60 per cent.; proteids, 6·80 per cent.; malt, sugar, and dextrin, 88·35 per cent. The composition of No. 2 Food (for infants and invalids) was as follows: moisture, 2·45 per cent.; mineral matter, 1·55 per cent.; proteid, 5·67 per cent.; malt, sugar, dextrin, and starch, 90·33 per cent. Food No. 1 is almost entirely soluble in water, while Food No. 2 is not quite as soluble, containing a small proportion of wheat flour, and is intended for infants aged eight months and upwards. The proportion of proteids in both foods is comparatively small which, however, is amply compensated for by the fac interesting example of hysterical word-deafness in a young girl who could hear all the noises going on around her but *could not understand the meaning of words* which were addressed to her. The lecturer impresses this fundamental notion—that there is no more one aphasia than there is one language, but that there are as many varieties of it as there are different modes of communicating ideas, and he points out that there are aphasias of transmission, or the mode by which we communicate our ideas to others, and aphasias of perception, or the mode in which we receive ideas of communication from others. Aphemia and agraphia belong to the first order and word-deafness is included in the second order. It is pointed out that aphasia is sometimes a consequence of uræmia, and it is shown how emotion may produce both deafness and blindness. In his concluding remarks we note that these hysterical aphasias habitually reflect that tendency to dissociation which is seen in other manifestations of like character, notably hysterical anæsthesias. As a rule hysterical aphasia assumes the clothing of hysterical mutism which is a pure motor aphasia, but it may take on the form of pure word-deafness or be associated with agraphia, and the duration of the disorder varies in one case or another, being long or short.

The other essays are equally characterised by minute analysis and learning, with due acknowledgment of the work done by others, and though the subjects are scientifically handled they are expressed in a very easy and readable form.

---

*Syphilis and other Venereal Diseases.* By H. de Méric, M.R.C.S. Eng., Surgeon to the French Hospital, London. London: Baillière, Tindall, and Cox. 1901. Pp. 132. Price 5*s*.

This little volume may be considered a brief practical account of the diagnosis and treatment of syphilis and the other diseases which are allied to it etiologically. It is not, and does not claim to be, an exhaustive treatise on the subject, but its very brevity will commend it to many practitioners who would be disinclined to peruse a larger work. We have spoken of the volume as practical, and its practical character is that for which we would chiefly commend it. We may not in all cases agree with the views set forth by the author, but they are evidently founded on a large experience of these diseases.

In the chapter on the Diagnosis of the Primary Syphilitic Sore from a "Simple Venereal Sore" Mr. de Méric rightly points out that it is less dangerous to mistake a syphilitic for a soft chancre than a soft for a syphilitic sore. In the former case the anti-syphilitic treatment will be merely postponed, while in the latter many months of needless mercurial treatment will have been carried out. The author in his account of the treatment of gonorrhœa prefers the local treatment by injections to the administration of drugs by the mouth, though if the local treatment does not produce a very marked improvement in a week or 10 days he commences internal treatment.

A chapter is devoted to the Prophylaxis of Syphilis and an interesting account is given of attempts at prophylactic and curative "syphilisation"

---

*Nursing; General, Medical, and Surgical, with an Appendix on Sick-room Cookery.* By Wilfred J. Hadley, M.D. Durh., F.R.C.P. Lond., F.R.C.S. Eng., Physician and Pathologist to the London Hospital; Lecturer to Nurses at the London Hospital Nursing School; Assistant Physician to the Chest Hospital, Victoria Park. London: J. and A. Churchill. 1902. Pp. 326. Price 3*s* 6*d*.

The modern English nurse has certainly very great advantages over her predecessors of some years ago. The training which she has to undergo is thorough and practical. There is a danger, however, of her becoming a mere machine, and to guard against such a possibility at most of the training schools for nurses lectures are given by medical *men, not only on elementary physiology* and anatomy, but also on such points in medicine and surgery as a nurse should know in order to take an intelligent interest in her work and to render her reports to the practitioner of substantial value. A "doctor" nurse is, of course, an objectionable being, and the lecturer has consequently to use great care and discrimination in dealing with his subject so as to say sufficient to guide the nurses without imbuing them with the idea that they can act for the practitioner in his absence. In the book now before us Dr. Hadley has been successful in steering the desired middle course, and nurses will find much that will be of great use to them in their daily duties. Occasionally, however, we consider that he has erred. For instance, his remarks on the Weir Mitchell treatment are quite inadequate, whilst we doubt whether a nurse should be entrusted with the difficult task of giving medicines through the nose by means of a catheter passed into the œsophagus. On the whole, however, we can recommend Dr. Hadley's book to those nurses who are desirous of maintaining, or adding to, their knowledge in the various branches of the nursing art.

### STERILISED MILK (SNIP BRAND).

("Vacca, Ltd.," Holland; London Agency, C. Dreyer and Co., Thames Chambers, Beer lane, E.C.)

An admitted drawback to milk sterilised by heat is the flavour of having been scalded which invariably results. Whatever method of sterilisation has been adopted for "vacca" milk it is certainly quite free from this "boiled" flavour. Its taste can hardly be distinguished from good, fresh raw milk. Yet, as our experiments have shown, the milk is quite sterile and keeps indefinitely in bottle. All attempts to produce decomposition or undesirable changes on exposing the milk for several days to the temperature of incubation failed. Further, the milk kept sweet for several days after the stopper of the bottle had been removed—a fact which might suggest the employment of an added antiseptic. But Dr. Klein has shown that when specimens of this milk were inoculated with bacillus coli it yielded "copious growth and typical changes." Cultivations made with the milk on agar plates and other nutrient media were found to be free from any growth after several days' incubation. In regard to the quality of the milk the following analysis of a sample submitted to us shows that it is well above the minimum limitations now prescribed by English law: total solids, 11·86 per cent.; fat, 3·20 per cent.; non-fatty solids, 8·66 per cent.; and mineral matter, 0·69 per cent. The following analysis made of a sample taken by ourselves independently from a stock just landed from Holland shows that the excellent quality of the milk is uniform: total solids, 12·38 per cent.; fat, 3·49 per cent.; non-fatty solids, 8·89 per cent.; and mineral matter, 0·68 per cent. As will be seen, it is a full-cream milk. The sterilising process is conducted in Holland under scientific supervision. Certain of the samples which we examined were quite a month old and the condition of them all was satisfactory, the most remarkable feature being the entire absence of "boiled" flavour. We could find no preservatives. The milk is retailed at 4*d*. per litre (that is, nearly an English quart). It is the first time that we have met with

THE LANCET.

*LONDON: SATURDAY, MARCH 8, 1902.*

## The Subjugation of Small-pox.

IT may be useful to review briefly the chief measures which are being taken in the metropolis to keep the prevailing epidemic of small-pox within bounds. It is now seven months since the disease was introduced, and what at first seemed likely to be a localised outbreak has spread over the whole of London, whence the disease has been imported into many outlying districts in the provinces. As regards London, at the present time, except in certain parts of the East-end, cases are but thinly distributed, but their existence demands unceasing vigilance lest any one of the invaded areas should become the centre of widespread contagion. The measures adopted to control this spread are based on principles which, with one important exception, are applicable to all infectious diseases, and in none do we meet with better illustration of the difficulties that have to be overcome to ensure success.

There is, in the first place, the difficulty arising from imperfect diagnosis. It is the "unrecognised" case which so often acts as the first spark in a wide conflagration; and in the case of small-pox the mild and greatly modified attacks common amongst the vaccinated may, and often do, pass unnoticed until the occurrence of secondary and more typical cases reveals their true nature. Secondly, there is the difficulty of securing the prompt removal of the sick from the neighbourhood of the healthy, followed by the thorough disinfection of the dwelling and its contents. That the contagium is given off very early in an attack is proved by scores of instances, and no doubt the degree of infectivity varies in different types of the disease. Indeed, infection may be transmitted from a patient prior to the definite appearance of the characteristic rash, and thus it not seldom happens that in spite of the removal of the patient at the earliest possible moment after notification some who have been in his company may already have become infected. This brings us to a third difficulty, one which is entailed in the adequate supervision of all who have been dwelling under the infected roof. It is not enough to have removed the patient, to have disinfected rooms and clothing, but all "contacts" must be carefully watched for a period of 14 days from the date of removal. It is impracticable and unnecessary for this to be done by quarantining these persons within the house or in a special building assigned for the purpose. That is an irksome and a costly measure quite unsuitable in large communities and only to be resorted to in exceptional circumstances. It is, too, a plan which has often broken down in practice, as, indeed, it did in the very town which claims the credit of having introduced this "system" of control. The futility of such quarantine has been shown in other diseases, but its replacement by the intelligent and continuous supervision of all who have been exposed to the chance of infection is both necessary and possible. The subject has been succinctly treated in a recent circular issued by the Local Government Board. After stating that quarantine is not needed "in districts in which sanitary matters are properly administered and vaccination and revaccination are efficiently carried out," it goes on to say that there is no material advantage to be gained by keeping the other inmates in the house after the removal of the patient. "They are not likely to infect other people, unless they themselves develop small-pox; and all that is required is to keep such persons under medical observation for a fortnight, and particularly to examine them carefully day by day towards the end of the second week from their exposure to infection, in order to ascertain whether any of them are developing small-pox. If none of them do so by the beginning of the third week from exposure, the revaccination (or vaccination) to which they were at once submitted on the occurrence of the first case in the invaded house should secure them from attack by the disease" At the same time the Board recognises that in some circumstances it may be wise to keep such persons confined to their houses under observation. We think, too, that it would be well if in every district there were places to which a "contact" who shows signs of febrile illness within the specified fortnight might be removed forthwith, until it be determined whether he is suffering from small-pox or not. There is also another difficulty which arises from the presence in our midst of the vast contingent of vagrants who fill the casual wards by night and roam through the streets by day. They may not only infect the workhouse, shelter, or common lodging-house, but may scatter germs abroad in their peregrinations. In times of epidemic every applicant for lodging in such places should be subjected to medical inspection. And there is, lastly, the difficulty of providing sufficient and safe accommodation for patients; so that every case may be isolated, whilst at the same time no risk may be run of the hospital becoming itself a focus for the dissemination of disease. On the latter point we would refer to the remarkable facts adduced in THE LANCET of Feb. 22nd (p 496) by Dr. J. C. THRESH and our comments thereon at p. 534, whilst from an article in our issue of March 1st (p. 612) it will be seen that in the matter of securing sufficient accommodation the Metropolitan Asylums Board is acting with praiseworthy foresight.

All these difficulties are being grappled with by vigorous efforts on the part of health authorities. Chicken-pox is made notifiable, in order that cases of doubtful nature may not pass unnoticed. The ambulance service has been extended and perfected to insure the removal of patients with the least possible delay. The plan of supervising "contacts" is being sedulously carried out, and those in charge of public shelters and lodging-houses are on the alert to detect suspicious applicants. It is a testing time for the health administration of London, and we believe that it is owing largely to the manner in which this organisation is framed and conducted that the present outbreak has so far been kept within comparatively small dimensions. We trust that by such continued vigilance the disease will be kept within manageable limits, but it would be too much to expect its early and entire cessation. The foci are too that they are to be used as adjuncts to diluted cow's milk. The foods consist largely of digested and transformed carbohydrate which is a valuable constituent so far as the needs of infant feeding are concerned. It is very correctly claimed that these foods are not complete in themselves, but that their addition to milk affords a diet lacking no physiological requirement.

### KETO METAL POLISH.

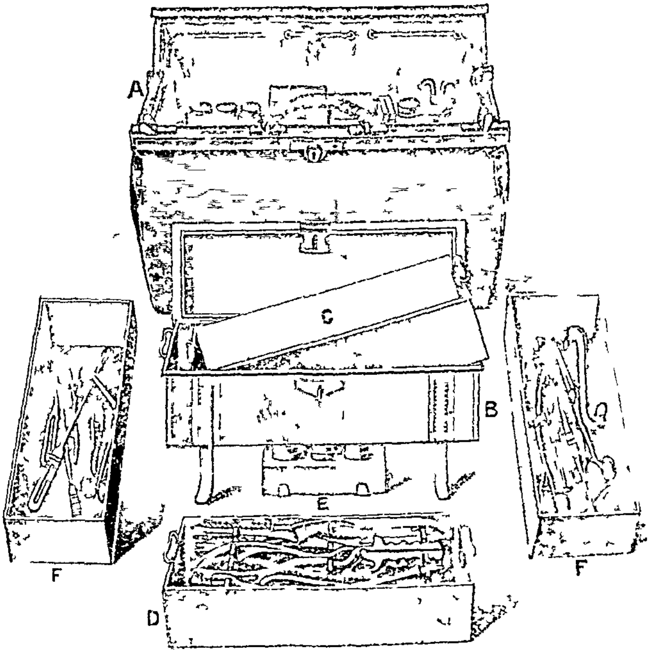
(THE KETO MANUFACTURING COMPANY, SMITHFIELD-STREET, LIVERPOOL.)

While, as we found, this preparation is an excellent metal polish it possesses no striking novelty in regard to composition. Moistened tobacco ash is one of the best metal polishes that we know. Keto somewhat resembles it in containing finely powdered chalk and an alkaline carbonate. It is a pink turbid fluid.

## New Inventions.

### A COMPLETE OBSTETRIC AND GYNÆCOLOGICAL OUTFIT.

I HAD long been impressed with the necessity of a complete outfit adequate to meet the needs of any obstetric or gynæcological emergency, but nothing in instrument makers' catalogues seemed to at all meet the requirements. The obstetric outfits usually described made no provision for those cases requiring abdominal section, whilst the provision for simpler cases appeared to be very inadequate. Yet the necessity of an adequate outfit is obvious. For instance, I was summoned to an obstetric case in which abdominal section was urgently indicated, but the telegram which I received gave me no indication of such a possibility and but for the fact that I brought with me the outfit to be described the patient would probably have died. In designing this my object was to be possessed of such an arrangement that, given any obstetric or gynæcological complication, I should at once be in a position to deal with it. The outfit has had a practical test extending over nearly 12 months and has stood the test very well. With the contents of this bag and without anything else I have performed various abdominal sections besides operations of a minor character. I append a description of the bag with illustration.



The outfit consists of a surgeon's kit-shape bag, strongly made in durable cow hide, opening square at the top, and fitted with removeable aseptic lining with a convenient series of pockets and adjustable loops for bottles, dilators, scalpel cases, chloroform apparatus, &c. (A). At the bottom of the bag are fitted a pair of aseptic metal trays (F, F), one fitting over the other and forming a box. Both of these trays when open become useful carbolising trays for instruments, &c., and when closed up are used for carrying instruments, dressings, &c. On the top of these trays is placed a specially designed portable combined steriliser and instrument case (B, C, D). B, the steriliser, is fitted with hinged lid and moveable legs. C is a deep inner tray fitting closely inside the steriliser B and used for carbolising the larger obstetric instruments after sterilising. D is the instrument frame with metal rack into which is conveniently fitted a complete set of obstetric instruments. This in turn fits closely inside the carbolising tray C. E is an improved double wick Schimmelbusch's safety spirit lamp. The bag as fitted is of course adapted to special needs, but the scheme is easily adaptable to individual requirements and I therefore describe it as I think it will be useful to others. Credit is due to Messrs. Allen and Hanburys for the way in which they have carried out the design.

RALPH VINCENT, M.D., B.S. Durh., M.R.C.P. Lond.,
Late Senior Resident Medical Officer, Queen Charlotte's
Lying-in Hospital, London.

Harley-street, W.

dead as a result of electric shock. The question of the mode of death by electric shock is not yet fully settled, but there is much to support the view that the heart is the most susceptible of the vital organs and that death from electric shock is very often death from arrest of the heart's beat. We are not yet in a position to say that this is the invariable rule in the fatal cases. In the non-fatal cases, where victims have been resuscitated after being apparently dead for half an hour or more, it is difficult to guess at all closely as to their actual condition. It is quite improbable that the human heart should be able to re-commence to beat if it has once been completely arrested for even 30 seconds, and if the condition were one of arrest of respiration it should be possible to feel the beating of the heart during the critical period which immediately follows the receipt of the shock. In one of the cases recorded by D'ARSONVAL and used as a basis for the rules laid down by him for treating a victim of electric shock in the same way as one apparently drowned the report states that the artificial respiration was not commenced until nearly half an hour had elapsed; and in that case it is difficult to believe that respiration had really been at a standstill for so long a time. Again, Mr. ASPINALL instances a patient who received a shock and was insensible but came round without assistance in 25 minutes. In another, who recovered after 45 minutes of artificial respiration, he tells us that the heart could not be felt and the breath did not cloud a mirror. Probably it is true that of those who receive shocks of great severity there are some in whom arrest of the heart is produced once and for all and that in these no known method of treatment is of any avail, while there are others who are not killed outright in this way but are left in a state of suspended vitality with heart and respiration almost arrested. From this state in time they may recover either without any assistance or with the assistance of artificial respiration. Artificial respiration should therefore always be made use of even if it be quite doubtful whether the condition of the patient is one at all resembling asphyxia.

◆

# Forsythe v. Law.

IT has seldom been our duty to comment on a more painful case than the one which lately formed the subject of investigation in the King's Bench Division of the High Court. The plaintiff, Miss FORSYTHE, a professional nurse, sued Dr. W. T. LAW for damages for alleged negligent and improper treatment, whereby her health had suffered and her ability to earn a livelihood had for a long period been at least seriously damaged. From the evidence it appeared that Miss FORSYTHE had been treated by Dr. LAW on and off since 1894. Unfortunately, the lady was the subject of many disquieting symptoms. Her heart was affected, she experienced febrile attacks with arthritic symptoms, and had a tendency to bronchial spasm which subsequently developed into a very acute form of asthma. Handicapped with this physical debility her constitution evidently was ill-suited to bear the strain incidental to the exacting duties of conducting a nursing home. Failing to relieve the spasmodic asthma by simpler remedies Dr. LAW resorted to the use of hypodermic injections of morphia. As time went on the patient unfortunately acquired the morphia habit. Discontinuance of the drug led to insomnia, which was met by the administration of chloral and other cerebral sedatives. The alleged malpraxis consisted partly of using the drugs in inordinate doses over a protracted period and partly in procuring them for Miss FORSYTHE and negligently placing them within her reach without let or hindrance.

So matters went on until through the interposition of third parties the patient passed into the professional care of other medical men, of whom Dr. J. KIRKLAND was one. This gentleman took a very decided view of Dr. LAW's treatment and a very active interest in Miss FORSYTHE'S welfare. He was perfectly justified in ordering the abrupt withdrawal of the morphia if he thought it proper to do so; although opinions are very much divided as to the best course to be adopted in such cases. As a matter of fact the reaction in the case of the plaintiff was dangerously severe, and Dr. KIRKLAND admitted in cross-examination that the patient came very near to death, collapse following the stopping of the morphia We think that the balance of evidence would hardly support his belief that it was not necessary to relieve insomnia. Professional judgment would scarcely subscribe to his unqualified impeachment of Dr. LAW whom he thought responsible for the lady's taking overdoses of chloral "because he must have known it." From the admissions in the witness-box it is certain that no one could imagine that Dr. KIRKLAND had not served Miss FORSYTHE zealously, though possibly indiscreetly, in so far as his professional brother, Dr. LAW, was concerned. We publish a letter in our columns this week from Dr. KIRKLAND, in which he pleads his proper professional regard for Dr. LAW; and while we are bound to believe his words we must also point out that we do not quite follow his reasoning. It was pleaded with unsurpassable force and eloquence by Sir EDWARD CLARKE, who must regret considerably having accepted the brief, that Dr. LAW had been guilty of gross misfeasance. There was something more in the indictment than a charge of mere negligence, since Dr. LAW was accused of having arranged "a mock consultation." His ability, attainments, and methods of action might have been called into question without a foul imputation being cast upon his honour. We endorse the statement by the jury that the action ought never to have been brought, and still more forcibly the stricture passed by Mr. Justice GRANTHAM on the unfairness of the way in which the plaintiff's case was conducted.

Miss FORSYTHE'S case differed in many respects from that of an ordinary patient. She was conversant with the action of the drugs that were prescribed for her and she must have known that taken in excess their influence would be extremely baneful. Dr. LAW acted somewhat unwisely, knowing the highly susceptible nature of Miss FORSYTHE, in procuring the medicines for her. In his own interest he should have fortified himself against the cruel fate which ultimately befel him. Nevertheless, it must be conceded that he was guilty of no dereliction of duty, for had he simply issued prescriptions for every dose in the most widely dispersed to be easily stamped out, and any day a wide extension might arise that would tax all London's sanitary resources.

Yet there is one measure applicable to small-pox, alone amongst common contagious diseases, which, if it could only be thoroughly enforced, would do more than anything else to check the progress of the scourge. By singular perverseness the legislature has placed the control of this measure in other hands than those responsible for the health of the community. In the absence of this powerful adjuvant the efforts of the sanitary service can only be partially successful. The risks of contagion may doubtless be diminished by sanitary improvements involving the better housing of the poor, the diminution of overcrowding, the enforcement of cleanliness, the freer supply of light, air, and water, and the right disposal of refuse, but none of these things, good as they are, go to the root of the matter. Every individual human being carries within himself the soil in which the germs of disease may be implanted. The soil must be made unfit for such noxious growth, and this, in essence, is what vaccination does. It is needful that vaccination should be efficiently performed, and repeated at intervals, and if this be done it is practically certain to avert the disease What more convincing evidence can be required of the truth of this assertion than that given by the facts recently published of the immunity of those persons employed at the hospitals of the Metropolitan Asylums Board, or, on a smaller scale, the experience of the nurses of the Stepney Infirmary. Yet there must be thousands of persons in London at this present time who have not availed themselves of this priceless prophylactic. Every person has it in his power to render himself safe from attack by small-pox. His neglect to take this step contributes to the persistence of the disease in the community. Therefore, to all the other difficulties in the way of those who are fighting the epidemic must be added this—perhaps the worst—because it is based on individual ignorance and negligence, and against stupidity even the gods strive in vain. The epidemic wave will pass in time, but very much can be done to check its career and to diminish its intensity by the general adoption of a practice of which the efficacy has been proved by the experience of all civilised nations during the century that has elapsed since its introduction.

◆

## Electric Shock.

Three papers of very considerable interest have just been read before the Institution of Electrical Engineers. They deal with the subject of electric shocks, and both the papers themselves and the discussion of them, which is to follow on March 13th, are likely to advance our knowledge of a somewhat difficult subject. Mr. Trotter's paper on Electric Shocks at 500 Volts is intended to correct the popular belief that accidental contacts with conductors at such a pressure are inevitably fatal. He showed by actual experiment during the meeting that he could endure the sensations produced by a brief contact with conductors at that pressure, and a millampère-meter arranged in the circuit gave readings ranging up to 30 milliampères as the current which traversed his body. The sensations, he said, were rather like those produced by touching a heated iron.

It is important to distinguish between the effects of brief accidental contacts with live conductors and those which might follow if the subject were so entangled as to be unable to escape from the position of serving as a conductor for a current at that pressure. 500 volts is a common voltage on circuits used for electric traction. On the Central London Railway the difference of potential between the middle line and the running rails is 500 volts, and the same difference of potential is maintained between the overhead wire and the rails of an electric tramway. In either of these systems, therefore, a passenger might accidentally come into contact with conductors having a difference of pressure of 500 volts, and would receive a shock which might feel very disagreeable, but the probabilities are that he would easily be able to extricate himself from the situation without suffering any material damage. A person falling off the platform at one of the "Tube" stations, for example, is not necessarily grilled alive, even if he should come into contact with the rails. A passenger on the outside of an electric tram-car would be better advised to sit still than to jump off headlong in the event of the overhead wire breaking and falling upon the car.

Mr. Trotter's paper and demonstration also emphasised the value of ordinary dry clothing as a protection against such pressures as 500 volts. Using a model section of the tract of the Central London Railway he not only stood upon the rails, but actually sat upon them and lay down upon them in sight of the assembled audience and the galvanometer indicated only a very few milliampères. The conclusions we may draw from his paper are, that it is a risky thing to take a deliberate hold of conductors having a potential difference of 500 volts, but that accidental contacts with them are only likely to give a nasty shock, and that ordinary users of electric railways or tram-lines are in no imminent danger of death from the electric currents

Mr. F. B Aspinall's paper, which we publish in this issue and which was read at the same meeting, raised many points of medical interest. He submitted to the medical and engineering professions nine very pertinent questions and then proceeded to elucidate them so far as he could from the facts which had come under his own notice. As the Institution of Electrical Engineers has very sensibly invited the attendance at the meeting of several medical men who are known to be interested in electrical matters it is quite likely that they may be able to add their counsels at the adjourned discussion. Mr. Aspinall suggests that the physiological condition at the time of the shock may be an important factor, and created some amusement by hazarding the suggestion that a man under the influence of alcohol was somewhat protected from fatal effects by his condition He also asked for information as to the importance of the path taken by the current through the body and for instructions how to resuscitate those apparently killed by electricity, and inquired for a simple and certain test by which to know whether a victim was dead or only in a state of suspended animation He mentioned several observations which led him to suspect that a person does not feel electric shocks when he is asleep, and he attached great value to D'Arsonval's method of treating by artificial respiration those who were apparently

These dealings accounted for three of the charges to which he pleaded guilty—namely, obtaining by false pretences the signing of the contract to sell the house and the obtaining of the horse and vehicle and of the £75. The two other matters which he also admitted at Liverpool were the theft of certain postal orders that fell into his hands when acting as locum-tenent, and bigamy, for incidentally in the course of his varied career he had been married once and had twice subsequently gone through the ceremony of marriage, his first wife being still alive. Before he was sentenced there were, moreover, other possible charges deposed to by London detectives, including the larceny of a horse and trap, the property also of a medical man, larceny of a silver flute and of electrical fittings, and an ingenious fraud, apparently the first of the whole series, perpetrated on certain financial agents and electrical experts. These he had deceived by an ingenious mechanical device into believing that a machine, which he claimed to have invented, was a new form of electrical generating apparatus, and they had accordingly formed a syndicate to develop the novelty and had paid him a salary as manager. Two other charges—the one of obtaining £50 by means of a worthless cheque, the other, larceny of a watch—were also mentioned. In connexion with the electrical fraud he had represented himself as formerly assistant house surgeon at St. Bartholomew's Hospital, and it was even stated that on one occasion he obtained, and for some months filled, the post of house surgeon at the Hope Hospital, Salford. It is not surprising that the cumulative sentences imposed upon him involve a fairly lengthy term of incarceration. The nature of the frauds, however, and the qualifications which enabled this remarkable scoundrel to perpetrate them may serve as a useful warning to members of the medical profession, and, so far as the circumstances are applicable, to other professional men as well. We presume that Burrows had testimonials of some kind that he could exhibit, and, as we have said, he could point to his assumed name in the Medical Register. To some extent, no doubt, he could also refer to persons for whom he had done work and whom he had in their turn deceived as to his qualifications. His career, however, would have been checked at many points had his victims taken the precaution properly to verify such references as would necessarily have involved his identity and his qualifications. We note, for example, that at one period he spoke of having a brother practising as a solicitor, but there does not seem to be a solicitor of the name mentioned in the Law List as in practice at the town he named. Again, a man seeking either the post of a locum-tenent or to purchase a practice cannot complain if he is asked to give references to medical practitioners or to the officials of the hospital at which he was trained. These, if followed up would, at all events, betray a flagrant impostor, even though testimonials and references may not always reveal the precise merits and demerits of the person who seeks to obtain a coveted position. It is, in any case, highly imprudent to reckon a total stranger to be honest merely because he is plausible, and to enter into business relations with him on the strength of his familiar use of the honoured names of persons of undoubted probity. The persons who, a man boasts, will be most happy to corroborate his own accounts of himself may, when properly approached, tell a very different tale from that predicted, and he who proffers them for the purpose cannot complain if he is taken at his word and application is made to them.

## THE DISTRIBUTION OF PLAGUE.

As regards The Mauritius a telegram from the Governor, received at the Colonial Office on Feb. 28th, states that for the week ending Feb. 27th there were 7 cases of bubonic plague, of which 3 proved fatal. As regards Egypt, during the week ending Feb. 23rd 8 cases and 5 deaths from plague have been reported from all Egypt. 5 cases and 4 deaths were reported from Tantah, 2 cases from Kom-el-Noor, a village near Mit-Gamr, and 1 case and 1 death from Alexandria. All these cases and deaths occurred among the native population. 3 of the deaths at Tantah occurred out of hospital.

## THE MIDWIVES BILL.

THE Midwives Bill which is now referred to the Grand Committee on Law has such important medical bearings that we need not apologise for constant recurrence to it. We wish to call attention to some of the points which were made by the various speakers in the debate on the second reading, whose speeches will be found fully reported in our present issue (see page 688). A careful perusal of these speeches must lead all medical men to the conclusion that the latest edition of the Midwives Bill has exactly the faults which its promoters at different times and in different ways declared that it has not. It tends to set up an inferior order of general practitioners and it is no great exaggeration to call it an infringement of the Medical Act. Lord Cecil Manners and Mr. de Tatton Egerton, respectively the proposer and seconder of the second reading, did not disguise this fact. The former spoke of the Bill as "putting the profession of midwifery on a par with the profession of medicine," and the latter approved of the absence of any regulation obliging midwives to take out an annual licence on the ground that "doctors did not have to take one out." Mr. Heywood Johnstone, speaking in a similar strain, considered that certified midwives would find it a humiliation to take out a yearly licence. Clearly all three speakers demand for the midwifery nurse the dignity of a professional status. They hold that because medical men, a highly educated body with a strict professional code and a recognised social position, are under no local control, the midwifery nurse should be equally exempt. Sir John Batty Tuke moved the rejection of the Bill in a sound speech. While he agreed with Lord Cecil Manners that the opposition to previous Midwives Bills had been due to difference of opinion on the precise legislation required rather than to disapproval of the general principles of the measures, he found that the present Bill did not go far enough to be practical. A Bill which does not penalise the work of the uncertified midwives seems to us to leave the parturient poor at the mercy of exactly those Gamps whose calling it was supposed to be the object of the Bill to suppress. Sir John Tuke's criticism of the Bill for the omission of the penal clause, which was contained in the 1900 version of the measure, elicited from Mr. Heywood Johnstone the somewhat remarkable statement that he had been informed in high quarters that it would be hopeless to attempt to carry the measure if it were encumbered with such a cause. The words are remarkable, not because there is anything unlikely in the statement that they contain—on the contrary, they have all the stamp of accuracy—but because they were uttered by Mr. Heywood Johnstone. For Mr. Heywood Johnstone is the gentleman who quoted this penal clause to us as a satisfactory reply to certain of our criticisms of the previous measure. Dr. Farquharson spoke in favour of the Bill in terms which proved it to be a long time since he took his medical degree. He seems to be unfamiliar with the needs of the present curriculum of medical education and with existing professional feeling. This is fatal to the value of any views he may hold, for, as Sir Walter Foster pointed out later, the subject of the Midwives Bill is one that has been growing steadily in complexity for the last 40 years. We hope that the Grand Committee on Law will perceive that Dr. Farquharson's opinion cannot be taken as representing medical feeling. In orthodox manner there was nothing whatever to prevent the patient—a professional nurse—from obtaining an unlimited supply of the drugs. Moreover, it was shown that during a considerable portion of the time that Miss FORSYTHE was under his care she was being tended by a sister nurse who would naturally be expected to exert a restraining influence. Had Dr. LAW rendered his services over a term of years for gain and profit—which is not customary when the patient is a nurse—there might have been more room for criticism, but what are the facts? He gave freely of his time, his skill, and his kind-heartedness for no other reward than the satisfaction of feeling that he was discharging a charitable office with the hope of alleviating human suffering. He acted the good Samaritan—not wisely, perhaps, but too well—and what was his reward? Scorn and contumely were heaped upon him by some who were and are to be pitied and by others who deserve severest blame. He will have the consolation which his merits deserve, given unstintedly by his professional brethren and by a generous and just public opinion. His legal and moral acquittal was complete.

## Annotations.

"Ne quid nimis."

### THE LONDON WATER BILL.

THE debate on the London Water Bill did not reach a very high level, and not one of the speakers apparently realised the importance of the matter from the point of view of the interests of the people of London. Mr. Long contented himself with formally moving the second reading of the Bill. In this he was wise. Mr. Buxton accused the Government of trying to get away as far as possible from the principle of direct representation in the election of the Water Board and lauded the County Council; but Sir John Dorington, one of the members of the Llandaff Commission, pointed out that the London County Council was out of court because it did not govern the district which was to be supplied with water, but only a part of it; that, moreover, the outside authorities strongly objected to be placed under the administration of the London County Council; and, finally, that severance of the supply in bulk (as proposed by the latter authority as an alternative scheme) had been clearly shown to be impracticable. These matters are familiar to our readers, but they appeared to be new to the House of Commons. Sir John Dorington criticised the Government proposal to create a Board of such an enormous size. He very rightly emphasised the point that in the case of purchase it would be much better if the administration of the Water Board could begin its work piece by piece. This is a most important point. If the Board were elected truly to represent the water consumers, and had the option of purchasing the businesses instead of being compelled to do so, the chief objections of fair-minded people to the present Bill would disappear. Mr. Boulnois and Colonel Lockwood, both water-company directors, made speeches calculated to enhance the value of the undertakings. They could do no less. Mr. Mellor, who was a member of the Llandaff Commission, criticised the unwieldiness of the proposed Water Board and appeared to think that if a purchase of the undertakings were made under the provisions of the Lands Clauses Act all would go well and that everyone would be satisfied—the London County Council, the representatives of the water companies, and even "the London ratepayer whose interests ought to be considered in so important a matter as this." The London ratepayers should be grateful to Mr. Mellor for his kind thought. At any rate, he does not, as everyone else in this difficult question seems to do, ignore the fact that the people who have to pay the bill and drink the water deserve consideration. But if the ratepayers knew all the facts we cannot believe that they would agree with Mr. Mellor. On the contrary, they would see that they can hardly do otherwise than lose heavily in a financial way should they be bluffed or cajoled into allowing the Government Bill to pass, especially with the improvements of Mr. Mellor and the water company directors incorporated. Sir John Maple criticised the Bill from a financial standpoint, and evidently did not consider that the Water Board as constituted under the Bill would include proper persons to fix the price to be paid for the companies' undertakings. Mr. Asquith declared for the London County Council as *par excellence* the proper water authority for London. Therefore he condemned the Bill entirely. His speech, coming from an eminent jurist and an ex-Home Secretary, cannot fail to be damaging to the Bill, even though it does not convert many members of the House of Commons to his estimate of the London County Council's claims. Mr. Walter Long with refreshing complacency decided that the Government must have struck the fair middle path because the measure was so opposed at either extreme. On the one hand the Government was told that the measure would be a grievous burden to the ratepayers, and on the other hand the water companies were protesting their forlorn condition under its provisions. The Bill was then read a second time, and after further debate was referred to a Joint Committee of both Houses.

### A SUCCESSFUL IMPOSTOR.

CHARLES WILLIAM BURROWS, who was sentenced by Mr. Justice Bucknill to seven years' penal servitude at the Liverpool assizes, seems to have had a surprisingly prosperous career during the last few years, and as he was able to make members of the medical profession his especial victims the history of his crimes is worth recounting in our columns. He was at one time apprentice to a chemist in Tottenham Court-road, and as such he is stated to have had charge of branch establishments. Making friends with medical students he attended lectures, apparently posing as a medical student himself, and in this character he acquired some knowledge of surgery. For a period after this he lived by his wits and otherwise, now playing in a theatrical orchestra, now travelling with a theatrical company, and now introducing to Brighton audiences a bullet-proof coat. In 1898 he seems first to have thought of turning his medical and surgical experience to advantage by purchasing a practice, and his subsequent actions were ascribed by his counsel at his trial to his failure to gratify this ambition, when a medical man who had promised to advance the necessary money declined to complete the transaction on discovering that the prospective borrower was not qualified to practise. In spite, however, of the drawback of impecuniosity he nearly won success by ingenuity. He assumed the name of Mr. James Joseph O'Donnell which appears in the Medical Register and had, it seems, no difficulty in obtaining temporary employment as a locum-tenent at Wigan. While there he learnt that a medical practitioner at Hindley wanted to sell his practice, and no doubt the fact of his being at the moment locum-tenent to a medical man strengthened his hand for his next move. The gentleman to whom he introduced himself at Hindley agreed to sell him his house for £1600 and his practice for £750, and he obtained from a third person on the strength of this transaction £75 in cash, to be expended on the purchase of furniture, as well as a horse and carriage from the vendor of the practice.

during growth by injudicious education, and was subjected during later life to hard stresses and struggles. It especially seemed certain that when the strangest and most inexplicable symptom of melancholia arose and persisted—viz., the tendency or impulse to suicide—that "such reversal of the love of life was the sure seal of nature that the death of the individual so affected was the right thing for the race." Even in the milder forms of melancholia the cerebral depression was followed by changes in bodily nutrition and metabolism. The gastric juice became defective in digestive power; the temperature, the pulse, and the arterial pressure were changed; the peristaltic action of the bowels was enfeebled; constipation set in; and secondary changes in the contents of the alimentary canal were brought about which led to toxæmia. The urinary and skin secretions were also changed, and after a time the patient began to waste and to lose weight. Such secondary toxæmic conditions completed the vicious circle of pathological processes, but the primary and immanent condition was "a hereditary brain weakness and instability without which toxæmia would not cause melancholia or adolescent insanity with its typical dementia—these together being by far the most numerous and the most characteristic of the psychoses." Dr. F. W. Mott's theory that the brain substance formed by its dissolution poisons which further destroyed it, seemed to need far more proof than he had given. Antitoxins were being investigated and used in the treatment of certain toxæmic insanities. Such methods were commendable, but they should be guided above all things by the fact that in very many cases it was the primary cortical disturbance which had caused the digestive troubles, the constipation, the urinary disturbances, and the excess of toxins and bacteria in the bowel as indicated both by the presence of leucocytosis and by the chemical study of the urine. So that while feeding and the administration of strychnine, iron and quinine, paraldehyde and alcohol, together with rest from work and worry, were the primary therapeutic necessities, the administration of calomel and salol as laxatives and intestinal disinfectants, and of diuretics and diaphoretics to promote secretion, was also indicated. On the other hand, there could be little doubt that toxæmic conditions played the chief part in general paralysis, puerperal insanity, and alcoholic insanity, and probably also in some forms of epileptic insanity. Most of the cases of climacteric insanity and the less acute cases of senile insanity did not exhibit during life or after death any proveable toxæmic symptoms, and finally there were examples of a common sort in which a solitary-living old maid or bachelor became melancholic and morbidly suspicious, and sometimes developed auditory hallucinations; all these mental symptoms resulted apparently from mere want of social stimulus to the brain cortex, just as a child became dumb through getting deaf, without any suggestion of toxic poisoning. Mental disease was, in short, too complex to fit any one theory.

## THE DEBATE ON THE ARMY ESTIMATES.

The House of Commons went into Committee on the Army Estimates on Tuesday last. Mr. Brodrick, in a speech which occupied two hours in its delivery, made his annual statement in reference to the army, and subsequently a debate took place on the concentration camps. Mr. Brodrick had an extremely difficult and complicated subject to deal with, but it cannot be denied that he handled it with marked ability, arranging and expounding his details with great clearness. Whatever may be the results of his proposals generally they are, at any rate, conceived on large and bold lines. As regards the changes which Mr. Brodrick seeks to introduce, his proposals for increasing the pay of the soldier, for doing away with the present vexatious and irritating system of stoppages, and for the establishment of more elastic and suitable terms of service with the colours and in the reserve, will, we think, commend themselves to the common sense of the community. Mr. Brodrick, while frankly admitting mistakes and shortcomings to have taken place, had, of course, a good deal that was very effective to say in vindication of his own department in the conduct of the present war. But it is to his remarks on the reforms intended to be introduced into the Medical Services and to the increased establishment of an Army Nursing Service that our readers will naturally turn with most interest. It will be seen, however, that the War Minister has not added much to our knowledge in these respects. While most people will cordially concur in the objects which he has in view and will be ready to accept his assurance that "everything that the wide experience of civil practitioners can bring to bear on the new system has not been lost sight of in drawing up the scheme," we should have been glad if he had at the same time told us that he had also availed himself of "the wide experience" of some army medical officers, surely useful advisers in the case of drawing up a scheme expressly designed for an army medical service Mr. Brodrick evidently believes that the new scheme will prove satisfactory, and so far as he describes it we may share his belief, but his description does not go very far. We obviously want to know a good deal more than he has told us in his speech in order to form a definite opinion in regard to it and we must be content to await the appearance of the promised warrant before pronouncing one. We know, for example, nothing as yet of the intentions of the Indian Government in regard to the War Office scheme and it has to be borne in mind that a large number of medical officers are always serving in that country.

## SENTIMENTALITY'S CASUALTY LIST.

There is no surer test of a man's culture or of his degradation than his manner of evincing sentiment and the causes which move him to it. Every human creature is sentimental to a greater or less degree, but in proportion as he is high in the scale of self-control and of intellect so is a man not the slower, indeed, to be moved, but the more reluctant to show to others the depth of feeling aroused within himself. When joy is the emotion that sways him he may perhaps wish his fellows to participate in the good fortune, but when he is the prey of grief the refined man closes his lips and hugs his sorrow. It is the savage races whose funeral rites are the most elaborate and among ourselves it is with the uneducated that sorrow makes the greatest show. Undertakers have their greatest importance in poor quarters and "plumes" wag more largely in the Jago than they do in Mayfair. It is not that sorrow is more acutely felt in the one instance than in the other, but rather that one class of persons is accustomed to control, another to expose, its emotions. Moreover, the educated have learned to consider always the effect of their actions upon others, whereas the poor man who is stricken feels only that he is not doing justice to the cause of his sorrow unless he makes a demonstration of his emotion. Such practices are sufficiently to be regretted when they lead only to ill-afforded expense and to a reaction of drunken hilarity. When the unbridled display of ignorant sentiment has dangerous and actually fatal issues it is a blow indeed to our vaunted education. In Essex lately a child died from diphtheria. The little girl's schoolfellows were allowed to kiss the body as it lay in the coffin. Other deaths among the children soon followed. No more cruel sacrifice to unthinking sentimentality could possibly be imagined. We place by the side of this another all the circumstances of the promotion of this Bill we do not hold out much hope to our readers of obtaining the modifications in it that are, in our opinion, necessary. The medical profession have not been united upon the subject, and the more temperate and influential critics of the different measures that have been before Parliament have been hampered by the violent language of those who are opposed to all legislation. As a result medical opinion and the opinion of the General Medical Council have not weighed with the legislature as they should have done.

## THE ARMY MEDICAL DEPARTMENT.

As will be seen by our Parliamentary Intelligence Mr. Brodrick, in answer to a question put by Sir John Tuke on Friday, Feb. 28th, said that the warrant bearing on the re-construction of the Army Medical Department would be issued before the vote for that department was taken. In introducing the Army Estimates on March 4th Mr. Brodrick implied that a hostile motion bearing on the new scheme had been put down.

## DURATION OF LIFE IN EPILEPTICS.

In a recent *Thèse de Paris* (1902) by Dr. J. Carton an attempt is made to obtain definite conclusions regarding the duration of life in epileptics, a subject on which much vagueness of idea has prevailed hitherto. The chief causes tending to shorten the life of the epileptic are gastro-intestinal disorders, pulmonary tuberculosis and septic pneumonia following inhalation of food particles during a fit, and injuries sustained in fits. Dr. Carton collected information regarding the ages and causes of death of 419 epileptics at the following asylums—viz, Clermont, Maréville, and Bicêtre, the patients being idiots, imbeciles, or feeble-minded. The following table gives the percentages of deaths at different age-periods in the epileptics referred to:—

| Age period. | Percentage of deaths. | Age-period. | Percentage of deaths |
|---|---|---|---|
| 5 to 10 years | 11 9 | 25 to 30 years | 8 6 |
| 10 ,, 15 ,, | 14 3 | 30 ,, 35 ,, | 6 2 |
| 15 ,, 20 ,, | 22 4 | 35 ,, 40 ,, | 4 5 |
| 20 ,, 25 ,, | 9 6 | 40 ,, 45 ,, | 6 2 |

Above and below these ages there were but few deaths—in all 15 8 per cent. of the total. The average age at death was 25 years and two months as deduced from the above table. Taking, however, different asylums it appeared that while the average age at death was 35 years and nine months among the patients at Clermont it was 39 years and four months at Maréville, 37 years and eight months in the department of the Bicêtre Asylum under Dr. Chaslin, and 20 years and four months in the department of the same institution under Dr. Bourneville. The last section included the largest number of patients of the general total, and the average age at death when all patients were included was, as already stated, 25 years and two months. A comparison of this with the age at death of other patients in the same institutions showed that the average age at death amongst the latter was 50 years, so that the shortness of life of the epileptic seemed to be clearly established. Among the chief causes of death the following were ascertained, as well as the proportions of deaths attributable to each cause: asphyxia, 1·2 per cent.; fracture of the skull by falling in a fit, 0·9 per cent.; pulmonary congestion, 7· per cent.; bodily malnutrition. 10 7 per cent.; pneumonia and broncho-pneumonia, 11·9 per cent . pulmonary tuberculosis 16 7 per cent.; and severe and prolonged fits, 31·5 per cent. The remaining deaths were due to other causes. It thus appears that while nearly one-third of the epileptic patients died from severe or prolonged convulsions, 35·6 per cent., or slightly more than one-third, died from pulmonary troubles, such as tuberculosis or pneumonia, while only a small proportion of deaths (2·1 per cent.) was due to asphyxia or to injuries sustained in a fit.

## SMALL-POX IN LONDON.

The returns of small-pox for the past week are as follows: on Saturday and Sunday, March 1st and 2nd, 63 fresh cases were notified and removed; on Monday, March 3rd, there were 90 fresh cases; on Tuesday, the 4th, there were 70 fresh cases; and on Wednesday, the 5th, there were 56 fresh cases.

## "DR. BELL" AND THE POST-OFFICE.

The issue of our contemporary *Truth* for Feb. 27th contains a statement to the effect that the editor of that journal has been indirectly responsible for the conviction of a blackguard named William Reid who was sentenced at the Lewes Assizes to six months' hard labour for sending filthy little books and other goods to a schoolboy. The master of the boy sent the contents of Reid's packet to the editor of *Truth* who forwarded them to the police authorities at Scotland Yard, with the result which we have recorded above. Now, if the police can act in this manner in the case of William Reid—the offence was apparently that of sending filthy literature through the post and the fact that such wares were sent to a minor had nothing to do with the case—why can they not do the same in the case of the scoundrel who calls himself Dr. Bell, who also sends dirty pamphlets through the post? On Jan. 28th, 1896, Dr. Bell, whose name was said to be Henry Walters, was fined at Marlborough-street Police-court in the sum of £20 and six guineas costs for using the titles "M.D." and "Doctor" without being a duly qualified medical man[1] Bell still continues to call himself "Dr." and to send out his abominable trash, or, at any rate, he was doing so last month. Will the police authorities take the matter up or will they not? If not, will Lord Londonderry think about it? We shall be happy to send his lordship half a dozen copies or so of Bell's pamphlet, together with sundry letters which have reached us from indignant correspondents.

## AUTO-INTOXICATION AS A FACTOR IN THE PRODUCTION OF CEREBRAL AND MENTAL DISORDER.

The toxæmic theory of disease has lately assumed a considerable degree of prominence in regard to insanity and cerebral disorders generally. In a contribution to the *Scottish Medical and Surgical Journal* for February Dr. T. S Clouston of Edinburgh deals with melancholia and the toxæmic theory of insanity. "The more one sees of mental disease in its typical varieties," says Dr. Clouston, "the stronger becomes our conviction that hereditary brain weakness is the prime factor in its causation" The argument as developed by Dr. Clouston was that by the application of the knowledge which we possessed many morbid brain conditions might, if treated early, be prevented from developing into actual insanity. Such measures to counteract mental disease ought to begin from birth Diet, environment, education, attention to infantile nervous ailments, choice of occupations, special training in habits of self-control, avoidance of alcoholic excess and sexual errors, and suitable choice of mates, were among the measures recommended as capable of being adopted in order to avert threatened mental breakdown in a predisposed subject. Emotional over-sensitiveness predisposed to melancholia, especially if such a condition was inherited from parents, was fostered indeed, may anti vaccinationists think with shame on those exquisite lines :—

---

[1] The Lancet, Feb. 1st, 1896, p 310.

> "Continuo auditæ voces, vagitus et ingens
> Infantumque animæ flentes ......
> Quos dulcis vitæ exsortes, et ab ubere raptos,
> Abstulit atra dies, et funere mersit acerbo."

The leaflet goes on to give hard facts and figures which should convince anybody who is not in the bond of invincible ignorance. We congratulate Mr. Wilson on his efforts to spread knowledge on the subject of small-pox and how to avoid it.

## THE VENTILATION OF THE HOUSES OF PARLIAMENT AND INFLUENZA.

THE bad ventilation of the Houses of Parliament is notorious, not because the system adopted is necessarily wrong in principle, but because, however perfect the means of changing the air may be, it is difficult to draw upon a fresh and healthy supply. The environment of the building is a grave obstacle to all attempts to provide the legislative chambers with healthy air. The conditions outside the Houses are such as probably to favour the multiplication of organisms whenever they abound. The river Thames is practically in contact with the south walls of the Houses of Parliament, acting as a cold-water jacket upon the air within, whatever steps may be taken to purify it. The air is thus constantly undergoing changes which render it unhealthy and take out that healthy property characteristic of a fresh breeze. There is something in the vitalising influence of fresh air which neither physiology nor chemistry can satisfactorily explain. It is, at any rate, pretty certain that, if perfectly pure air, obtained by mixing pure chemically derived oxygen and nitrogen in the proportion contained in the atmosphere, could be prepared on the large scale, it would not meet the needs of healthy physiological requirement in the same way as fresh natural air does. Artificially heated air is frequently described as "stuffy" and the French physiologists describe such air as "*devitalisé*"—a not inappropriate word. Foul air or unfresh air saps the power of the body to resist disease and hence the prevalence of disease, and especially respiratory disease, such as influenza, amongst those who habitually attend more or less crowded places or places where the air lacks its natural freshening effects. Thus senators in Parliament, judges in the courts, and the clerks in banks and insurance offices show a large percentage of epidemic influenza. In reply to questions this week in the House of Commons on the prevalence of influenza in the assembly no hope was held out that the condition of ventilation could be improved.

## MEDICAL OFFICER OF HEALTH AND PUBLIC ANALYST.

WE expressed before now the opinion very definitely that municipal bodies are not well advised in combining the appointments of medical officer of health and public analyst. Such a combination for obvious reasons cannot be for the public advantage. Nowadays the science and practice of public hygiene are quite sufficient in themselves to occupy all the time of a medical officer who discharges his duties efficiently, in which case he is prevented from giving that systematic attention to laboratory work which is essential to the performance of the duties of the public analyst. The duties of a medical officer of health are quite exacting enough in regard to sanitation without the additional burden of having to undertake the analysis of some hundreds of samples of foods and drugs per annum. This has already proved to be the case in some of the municipal boroughs where one man formerly occupied the two posts, and where now the medical officer and the public analyst are two independent men, acting in coöperation. The same situation has just been arrived at by the Health Committee of the Birmingham City Council, which has reported that the duties attached to the office of medical officer of health require Dr. Alfred Hill's undivided attention. Dr. Hill himself pointed out to the committee that the work of the joint appointments of medical officer of health and public analyst is too much for one man and asked to be relieved from the duties of the latter office. The committee was sensible enough to concur in this opinion and it decided to appoint a public analyst at a salary of £350 per annum, the medical officer's salary, considering that he devotes the whole of his time to the service of the corporation, being permitted to remain as it was when he held both posts. Other municipal bodies will find that they will be compelled to adopt a similar course.

## STREET LETTERING AND LOCAL AUTHORITIES.

THE new broom is understood to sweep clean and certainly there are reasons why it should be able to do so. Yet it not infrequently fails to justify its thorough-going character. Even the especial broom which has been placed in the hands of borough councils might be better employed for the removal of sundry public inconveniences than it has been. For the present we will mention only one such. The wayfarer on our streets is usually in search of some particular house. By day he should succeed, even if a stranger, in finding a labeled corner which will serve him as a guide. The surer help of local informants is also available. After a time he arrives at his destination. The door is probably numbered, but above it as often as not is a sheet of plate-glass, either plain or fancifully uninstructive. He does not notice all this at the time But how does he fare if he has to make the same journey for the first time after dark? The streets are deserted, the scarce policeman is not near, and the lettered angle, clearly enough read in sunlight, is little better than a Coptic text in the mellowed light of a street lamp several yards distant. On that lamp there is no inscription. It is only with the joint assistance of patience, ingenuity, and fortune that he reaches the street he is making for, and happy is he then if he quickly finds his number on doorways glazed with blank nothing or with romantic names or floral devices. This is the ordinary lot. The medical practitioner who wanders forth at the call of duty in the small hours of the morning has even less light upon his quest unless he have a messenger to lead him, which he has not always Surely the public and he may reasonably ask local authorities to help them in this matter. We admit that these have done something, but much remains to be done, and the work is not such that any great outlay should be required to complete it. We would have every street and corner labeled with bold and bright enamelled lettering (as not a few fortunately are), every corner lamp similarly inscribed upon the glass (as a limited number are), and the glass plate over every house-door plainly numbered. If this plan were carried out, and by order, what comparative convenience and facility would result and what needless waste of time would be prevented.

## LIVERPOOL UNIVERSITY: A MUNIFICENT GIFT FOR MEDICAL RESEARCH.

THE sum of £25,000 has been given by Mr. William Johnston, shipowner, of Liverpool, for furthering the university movement in that city. The money will be devoted, in accordance with the wishes of the donor, to promote research in pathology and physiology. The £25,000 are divided as follows: £10,000 are allocated to found a chair of chemical biology; £6000 at 5 per cent. interest are allocated permanently to endow three Research Fellowships of £100 a year each. Of these Fellowships one is to be held by a medical graduate of a colonial university, a second by a graduate of medicine of the United States, instance where sentiment certainly cannot be blamed, but where ignorance is the factor in common with the above example. This case is *à propos* inasmuch as it illustrates well one of the dangers arising from the uninstructed midwife. A young married woman died one week after her confinement. She had been attended "as casual nurse by a Mrs. Greenroyd who in addition to this duty performed work as a charwoman at a house where there was scarlet fever. The fever was in this way communicated to the lying-in woman who died two days after from a very malignant form of scarlet fever." The coroner, it is satisfactory to read, allowed the body to be viewed through a window, the coffin containing it having been unscrewed and placed on chairs for the purpose. The action of the mothers of the children who died from diphtheria, and the action of the coroner, afford a striking contrast between the cruelty of ignorance and the kindness of science. The coroner protects his jury, a body of men with a bare business relationship to himself; the sentimental mothers bid to an infectious death children for whose safety probably they would have been willing to make any sacrifice. From the poor girl who jumps into the river because she is unloved to the small-pox victim who will not have "matter from an animal put into him" misguided sentiment in one way and another claims a long list of victims.

## SCOTTISH POOR-LAW MEDICAL OFFICERS.

WE have on many previous occasions commented upon the grievances to which the Scottish Poor-law medical officer is exposed. But we have rarely come across an exhibition of more spiteful malignity than the proceedings of the Parish Council of Clyne at a meeting held at Brora on Feb. 11th and reported in the *Northern Times* of Feb. 13th. After the opening of the meeting had been much disturbed by sundry rowdy malcontents and the venue had been changed from the council chamber to the Temperance Hall, a letter was read from Peter Sutherland lodging complaints against Dr. G. Nicoll, medical officer of the parish of Clyne. Mr. Sutherland having remarked that he was not a pauper, the chairman stated that the council had no right to interfere with a practitioner's private practice. At this obvious truism there were "booing and groans, and shouts of 'whose duty is it if not the Council's?'" Mr. Sutherland's letter was then read and the charge was as follows. On Dec. 21st, 1901, his child was ill. Dr. Nicoll was called and he examined the child. He also came on Dec. 27th and 28th. By the evening of Saturday, the 28th, the child was seriously ill and Dr. Nicoll was sent for but could not be found. He eventually came on Sunday evening. In the meantime another practitioner, Dr. Simpson, had been telegraphed for, but did not arrive until just as Dr. Nicoll was leaving. The child had diphtheria. Mr. Sutherland wound up his plaint by saying: "I am a poor man. My child is dead and I will have to pay for Dr. Nicoll, and I will have to pay Dr. Simpson about £1 besides. As you are responsible for Dr. Nicoll and I could not find him and therefore had to call Dr. Simpson I hold you responsible for Dr. Simpson's account." Mr. Melville said that it was very hard that the people of Clyne had to send to other parishes for a doctor when they required one. Mr. Hamilton followed in the same strain. The chairman having advised Dr. Nicoll to resign the matter *dropped*. A public meeting then followed at which Mr Hamilton spoke. He is reported as speaking thus: "The doctor must resign. It is too bad for us to have doctors coming from other parishes. ...... It is the ratepayers that pay his salary and not the parish council, and I consider that it is the council's duty to see that the people get justice." Finally, the meeting decided that the parish council should within 14 days ask Dr. Nicoll to resign at once or within three days of his receiving notice. We take this opportunity of remarking that a "parish doctor," or, to give him his right title, a "medical officer to a parish under the Poor-law," is not, like the parish pump or the parish church or the parish stocks, able to be made use of by anyone simply because he or she happens to be a parishioner. A parish medical officer is a duly-qualified gentleman elected by a board of guardians to look after at a certain salary the sick paupers within the limits of the parish. The Melvilles and Hamiltons of Clyne seem to think that the parish medical officer is bound to go to anyone in the parish who may send for him, presumably with no further fee than his salary for looking after paupers. We are glad to see that Mr. Sutherland acknowledged his indebtedness to Dr. Nicoll; but he had no right to intrude his private dispute with his medical man upon the parish council, neither had the parish council any business to consider the matter, and why the Hamiltons and Melvilles should poke their noses in we fail to see. If Mr. Sutherland feels neglected, his course is to bring an action for malpraxis.

## THE ANNUAL DEBATE AT THE CHELSEA CLINICAL SOCIETY.

TWO special meetings of this society will be held in the Jenner Institute of Preventive Medicine, Chelsea-gardens, Grosvenor-road, S.W., on Tuesday, March 11th, and Tuesday, March 18th, 1902, at 8.30 P.M. The subject for debate is Cancer, its Nature, Origin, and General Principles of Treatment, and the following gentlemen are announced as intending to take part in the discussion. On March 11th Dr. J. F. Payne (who will open the debate) will be followed by Dr. John F. W. Tatham, Professor R. T. Hewlett, Dr. G. T. Beatson, and Dr. J. Galloway, while a paper will be read by Dr. H. R. Gaylord (New York) on Cancer in Swine, with lantern slides. On March 18th Sir William Mitchell Banks will open the debate and will be followed by Mr. H. G. Plimmer, Mr. A. Pearce Gould, Mr. A. W. Mayo Robson, and Mr. A. Marmaduke Sheild. A communication from Professor Adami of Montreal will be read and Dr. A. Barry Blacker will demonstrate the present position of treatment by means of x rays and ultra-violet rays and show the apparatus. Any member of the medical profession will be welcome to the debates on presentation of his card.

## THE RELATION OF THE CHURCH TO SANITARY REFORM.

SOME time ago we adjured the clergy to preach vaccination and revaccination and we are glad to know that our advice fell on heeding ears. The Rev. Harry Wilson, who is well known as an earnest and energetic parish priest in a very poor part of London, tells us that he preached on the subjects we mentioned and he adds: "I only wish I could get as much obvious result from my ordinary sermons as came from this one, as I am glad to say that the great majority of our people have been revaccinated." Mr. Wilson has had the *substance of his sermon reprinted as a* four-page leaflet, a copy of which he has sent us. Over 8000 copies of it have been sold and the matter is excellent. Perhaps the commencement might be called sensational, but nowadays sensationalism, if the facts stated are true, is necessary to catch the understanding of the average man or woman. *Here* are the words: "In the town of Gloucester there is a beautiful cemetery and in one corner of the cemetery there are the graves of no less than 280 little children, all under 10 years of age, all of whom died seven years ago when a terrible attack of small pox visited that town. Of these 280 children who died of small-pox 279 were unvaccinated and only one was vaccinated." Well, depend on the form of the stone as on the general irritability of the patient, and especially on irritability of the bladder. Thus you will sometimes in performing the operation find a stone excessively pointed, where the patient complains of but trifling symptoms; and on the other hand, when the stone is perfectly smooth, the patient suffers extreme pain. The pain, therefore, depends more on the irritability of the bladder and the constitution of the patient, than on the form or surface of the stone; *cæteris paribus*, however, rough stones will give the greatest degree of pain.

There are four different kinds of calculi, when chemically examined. A very nice examination may lead to further discoveries on this subject; but at present we are only acquainted with four species. The first is the uric acid, which is a common, but not the most common form of calculus. The second is the triple phosphate, or ammoniaco magnesian phosphate; the third species is the mulberry, or oxalate of lime, an excellent specimen of which occurred the other day in the boy at the other hospital. The other species was lately discovered by Dr. Wollaston, a most admirable chemist, and one of the first philosophers of the age, who developes every subject to which he applies his active and powerful mind, with an extraordinary degree of minuteness and accuracy. In examining the different calculi he discovered the species which I am now mentioning, to which he gave the name of the cystic oxide. With respect to the uric acid, it is distinguished by concentric lamellæ, and when cut has the colour and appearance of wood. (The learned Professor exhibited a specimen to the class.) It is soluble in alkalis, and alkaline medicines are therefore commonly recommended for this kind of stone.

# THE DEBATE ON THE MIDWIVES BILL.

## A FULL REPORT OF THE SPEECHES.

In The Lancet of March 1st we gave a brief outline of the debate on the Midwives Bill which took place in the House of Commons on Feb. 26th. We give now a detailed report of the speeches as the matter is of paramount importance to the medical profession, and have commented elsewhere upon the different views expressed.

Lord Cecil Manners moved the second reading of the Bill. He explained that the fortune of the ballot had made him responsible this session for the introduction of the measure, and while he believed thoroughly in the merits and general principles of the Bill he did not claim to have made an exhaustive study of the questions involved. This was a subject which had frequently come before the attention of Parliament. In 1878 a Bill was introduced and since then almost every year there had been a Bill. In 1892 a Select Committee reported to the effect that no woman should be allowed to call herself a midwife or to practise as a midwife except under suitable regulation, and again in 1893 it reported to the same effect. In 1900 a Bill drafted on the lines of these reports passed the second reading by a majority of 90 votes, and was successfully carried through the Grand Committee, but unfortunately it was too late in the session when it reached the report stage. The hon. Member then quoted resolutions of the General Medical Council and the Royal College of Physicians of London with a view to showing that there was a consensus of opinion among medical men in favour of legislation with regard to midwives. He ventured to say that the opposition which the Bill had hitherto met was more owing to the fact that experts differed as to the precise legislative action that should be taken than to any feeling that legislation was unnecessary. The hon. Member then proceeded to describe the existing state of things, the incompetence of many midwives, and the dangers to which women and their offspring were exposed in consequence of that incompetence. This country, he said, was the only civilised country, certainly the only country in Europe, where there was not some sort of registration and regulation of midwives. There were about 450,000 cases of childbirth in England each year which were attended by midwives alone, and most of these women were absolutely untrained and incompetent. The first object of the Bill was to secure proper training and the method by which it was proposed to secure it was the appointment of a central board of seven members, of whom four would be registered medical practitioners. This board would frame regulations for the training of midwives and their admission to registration, and for restricting their practice within proper limits. Certificates would be granted which would enable persons seeking the services of midwives to discriminate between trained and untrained women. In this respect the Bill followed closely the Medical Act of 1858 which laid it down that it was expedient that persons requiring medical aid should be enabled to distinguish the qualified from the unqualified medical practitioner. This Bill, in fact, put the profession of midwifery on a par with the professions of medicine and dentistry and veterinary surgery. He thought it would be unfair not to put the profession of midwifery on a par with these professions. The local supervision would be entrusted to the county council with power of delegation to the district councils, and would be secured by a system of notification similar to that under the Infant Life Protection Act, which he thought would be sufficient to ensure the identity of the woman and to trace her qualifications and character. He assured the House that when the Bill reached the committee stage its promoters would gladly welcome any suggestions for its modification or improvement, and what he asked the House to do now was to affirm the principle that those who desired the assistance of these women should be enabled to distinguish between those who were competent to give it and those who were incompetent.

Mr. De Tatton Egerton seconded the motion. The efforts for legislation on this subject began, he said, not in 1878, but as far back as 1813, when the Society of Apothecaries of London endeavoured to get a Bill. In 1878 the General Medical Council considered the matter so important that in that year they promoted a section which had reference to the organisation of midwives. In order to carry their Bill the Council found it necessary to drop this section because it was feared that it might make some confusion between medical men and midwives. Since that time the subject had been very well threshed out in the country. Several Bills had been before Parliament in order to try to remedy what he could only call a disgrace to this country—that there was no restriction whatever upon either the use of the title "midwife" or the employment of unqualified women. In Austria this legislation dated back to 1810, in Belgium to 1818, in France to 1803, in the Netherlands to 1865, and in Norway and Sweden to 1810. He had not been able to get the dates for Russia or Prussia, but in both these countries the regulations with regard to midwives were very stringent indeed. The General Medical Council, which had been one of the principal opponents of this Bill when it had been brought forward during the last three or four years, had a Bill prepared of its own, but it had never thought fit to bring it forward for discussion in that House. It had taken up the position, he would hardly say of the dog in the manger, but while it had not brought in its own Bill it had done all it could on every occasion to wreck the Bill of those whom he had the honour to represent. The General Medical Council in its last attack, said that the midwife should be required to take out a fresh licence. The Bill proposed that she should be certified and that the sanitary authority of the district should see annually that she was residing in the district and was doing good work. The legislature did not ask that a medical man who went to reside in a district should take out a licence annually, and why, he asked, should this condition be imposed upon a midwife? The Council also objected to the proposed constitution of the Central Board; it wished to have the whole matter in its own hands; it seemed to forget that there were other interests in the country besides its own. According to the Bill, there would be on the Board a majority of medical practitioners registered under the General Medical Council, and this, he thought, was as much authority as the Council required and ought to have. The promoters of the Bill had during the past three or four years had various deputations to the Privy Council. They had been assisted by the Privy Council with advice, and the Bill now before the House was the result of a meeting that had been held in conjunction, not only with the Privy Council, but also with the Home Office and the Local Government Board. At the meetings of the Privy Council they had received the most generous support, not only from the obstetric medical men, but from the Women's National Liberal Association, the Incorporated Midwives Institute, the Women's Industrial Council, the Women's Liberal Federation, and representatives of the body of and a third by a research student in gynæcology. The remaining £9000 are to be spent in building a laboratory adjoining the Thompson-Yates Laboratories, to accommodate the Tropical School, the professors of chemical biology, experimental medicine, comparative pathology, and the serum research department.

## LEICESTER AND VACCINATION.

ON March 5th the Lord Chief Justice, Mr. Justice Darling, and Mr. Justice Channell gave judgment in the case of Moore *v.* Keyte. The case was an appeal from a conviction by the Leicester magistrates under the Vaccination Acts, the appellant having been prosecuted by the vaccination officer against the orders of the guardians. The most important question before the court was whether the vaccination officer had powers to prosecute without the consent, or against the wishes, of the guardians, and the *court unanimously held that he had such powers.*

SIR FRANCIS JEUNE, President of the Probate, Divorce, and Admiralty Division, and Mr. Justice Barnes have ordered the following notice to be put up in their courts: "If any person to whom an oath is administered desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland, he or she is permitted to do so. The following form of oath may be used—'I swear by *Almighty God that* I *will speak the truth, the* whole truth, and nothing but the truth.'" We trust that this excellent example will be followed by the other judges.

A MEETING will be held in the Governors' Hall of St. Thomas's Hospital on Tuesday, March 11th, at 4.30 P.M., Mr. J. G. Wainwright, J.P., the Treasurer of the hospital, in the chair, to consider the steps to be taken to raise a memorial to the late Sir William Mac Cormac, Bart., K.C.B., K.C.V.O., *and to commemorate* his *connexion* with *the* hospital and the medical school.

THE medical profession is asked to note that the permanent address of the *Odontological* Society of Great Britain is now 20, Hanover-square, London, W.

# Pharmacological Notes.

### DETERIORATION OF ALCOHOLIC SOLUTIONS OF PEPSIN.

EUG. THIBAULT[1] has studied the effect of alcohol on the activity of pepsin, varying the strength of the alcohol and the duration of the experiments. He finds that, provided the alcoholic strength is *below* 12.5 per cent., the solution shows no immediate loss of strength, but above this strength *the solution immediately undergoes deterioration.* The peptonising power of the solution is almost destroyed at the end of four months, whether the alcoholic strength be above or below 12.5 per cent. Hence it appears that pepsin should not be prescribed in the form of pepsin wine, as the ferment is destroyed to a greater or less extent according to the age of the liquid. It is pointed out that sugar and certain other substances present *in the wine have a* partial preservative effect.

### THE ACTION OF PEPSIN, TRYPSIN, AND PAPAIN.

G. R. Baldwin and P. A. Levene,[2] after studying the action of proteolytic ferments on toxins, find that the diphtheria and tetanus toxins are digested, and not simply neutralised, by pepsin, trypsin, and papain. *They* are thereby rendered inert. Tuberculin, a nucleo-proteid, is weakened in its *action by these digestive ferments; prolonged digestion with* trypsin, but not with pepsin, destroys its activity.

### VALUE OF UROTROPIN.

According to W. F. Lœbisch,[3] urotropin or hexamethylene tetramine is a good antiseptic, causes no bad symptoms, and lessens intestinal putrefaction. The ethereal sulphates of the urine are diminished.

### LECITHIN IN TUBERCULOSIS.

H. Claude and Aly Zaky[4] recommend lecithin as an adjuvant to other means of treating tuberculosis from its specific action on the elimination of phosphates in the urine and its beneficial action on nitrogenous metabolism.

### ACTION OF SUPRARENAL EXTRACT.

*John N Langley*[5] *finds that suprarenal extract* causes a brief but active secretion of the salivary and lacrymal glands. *This is not affected by degeneration of the post-*ganglionic fibres of the superior cervical ganglion or by small doses of atropine, but the secretion *is stopped by* large doses of atropine. The extract has no certain effect on the secretion of sweat, but increases the secretion of bile. It acts differently on different involuntary muscular organs, causing, for instance, inhibition of the bladder, stomach, and gall-bladder, and contraction of the anal sphincters, uterus, and blood-vessels. The theory that the extract acts on sympathetic nerve-endings breaks down in various instances.

### PHARMACOLOGICAL ACTION OF PURINE DERIVATIVES.

An *important investigation* has been *made* by Oswald Schmiedeberg[6] on the comparative pharmacological actions of some purine derivatives. Experiments were made with frogs and rabbits. The action of caffeine and theobromine is already known to be twofold—viz., nervous and muscular. The nervous action depends on the presence of nitrogen in the molecule, for it is exhibited also by ammonia and by ammonium salts. The muscular action is characteristic of the purine nucleus. Purine itself exhibits both actions, which are affected in degree by introduction of oxygen or alkyl groups. A large number of substances have been experimented with and their effects have been described.

FROM

## THE LANCET, *SUNDAY, MARCH* 7, 1824.

### LECTURE 39[1]

*Wednesday Evening, March 3d.*

A *few minutes after* 8 o'clock the Learned Professor entered the Theatre. Several pieces of orange peel lay strewed upon the table on which the preparations are placed. This, said the learned professor smiling, as he *took* up one of them, is, I presume, *one of the missiles!* We trust that this good natured rebuke will have more weight with the class than any formal argument, to show the folly of the puerile practice which prevails during the half hour preceding the Lecturer's entrance.

In the last evening's Lecture, gentlemen, I began to describe to you the subject of the formation of calculi, the different species of calculi, and the symptoms which attend them. I shall now proceed with this subject. The pain which a patient experiences from stone in the bladder is by no means in proportion to its bulk. It is not exactly in the inverse ratio to its *magnitude,* but *still it approaches that* inverse ratio. When a stone becomes excessively large, the patient generally loses the power of retaining his urine, and the distillation of urine from the bladder, prevents that contraction of it which *occasions so much pain to the patient* in discharging the last drops of it. Doctor FRANKLIN, the celebrated American philosopher, who died of this disease, suffered excessively for a number of years from it, but at last, when the stone acquired considerable magnitude, he experienced but little pain. The pain does not so much they all deplored. He did not think, however, that his hon. friend had quite fairly quoted the provisions of Clause 3, the effect of which was that any midwife who was now in practice must bring evidence satisfactory to the Board showing that she was not only a woman of good character but in *bonâ-fide* practice. His hon. friend omitted the *bonâ-fide* practice point, which was important.

[1] Excerpt from report of this lecture delivered by Sir Astley Cooper in the Theatre of St. Thomas's Hospital.

Sir **John Tuke**: It was merely an accident on my part.

Dr. **Farquharson**, resuming, said that he took his stand on the broad general principle that it was high time something was done to remedy the present condition of affairs. Public opinion had been aroused and there had been evidence before two select committees that a great evil existed and ought to be remedied as soon as possible. They could not end the midwife, but it was reasonable that they should attempt to mend her. Every year 450,000 cases of female labour were attended by midwives. Many women preferred midwives. If he were a woman he would naturally prefer to be attended by a woman at a time when the softness and sympathy of a woman were so useful. It was perfectly well known, of course, that many midwives were ignorant and dirty, but he thought that, like medical students, they had suffered a little at the hand of comic writers, and if they were, in many instances, dirty, ignorant, and incompetent, then they must be educated and made less injurious and dangerous. He ventured to say that parturition was a purely mechanical process. In 99 cases out of 100 it was perfectly easy and natural and could be carried out without any difficulty whatever. He hoped that he would not offend the prejudices of any by saying that the reason why Edinburgh was always considered such a good school for midwifery was that the large size of the Scotch skull made the process of parturition more difficult than in England. Two or three months' training or 10 or 20 lessons would be quite enough to let a woman know how to deliver another woman in childbirth, and he was bound to say that with that training a midwife would know quite as much as did many medical men. When he took his degree in Edinburgh attendance at six labours was sufficient to qualify for midwifery, and if that was enough to give a man a knowledge of this particular branch of his practice, would not a woman who had probably attended 200 or 300 cases know as much as a man? He admitted that the Bill was not quite perfect, but it was a serious and an honest attempt to remove the evil. There would be a sufficiently good curriculum established by the Board, which was not at all a bad Board. It was not constituted by the General Medical Council, which had got quite enough to do with other things, but by the Privy Council, and it had to be accepted and supervised afterwards by the General Medical Council. It had been objected that the penal clauses were not introduced. That was a hopeless utopian dream. No House of Commons under the sun would ever pass provisions of that kind, and all that they could do was to give some kind of hall-mark which would enable the public to see who were qualified and who were not. He was glad that the honourable Member who moved the rejection of the Bill did not take the objection that the Bill would do harm to the medical profession. That was a line of argument which he repelled with indignation on the part of his profession. But it had been said that 95 per cent. of the medical practitioners were against it. Why? He hoped not on account of their own interests. What was the reason?

Sir **John Tuke**: The absence of the penal clauses.

Dr. **Farquharson** said that he was very glad to hear that, but, as he had already indicated, he did not think that any body of reasonable men would ever pass clauses which would do more than protect the public against the unauthorised practitioner. There was an argument put forward by Professor Horsley—namely, that the Bill would go far towards repealing the Medical Act by making midwives equal to those who were qualified by that Act—but he contended that anyone who used that argument could hardly have looked at the Bill, as the text made it quite clear that such a result could not take place.

Mr. **Griffith-Boscawen** supported the view that there should be a penal clause to prevent women who were not certified from practising.

Mr. **Eugene Wason** said that the promoters of the Bill would have liked to take the General Medical Council along with them, but as they had had to take their choice between the Government and the Council he thought that they had done well to secure the allegiance of the former.

Sir **Francis Powell** supported the second reading in the hope that the Bill would be strengthened in committee.

Mr. R. **Ambrose** said that he opposed the Bill because it created a distinct and inferior class of practitioners in midwifery over whom the General Medical Council could exercise no control, and because it contained no provision for qualified medical assistance in cases of difficulty.

Mr. W. **Lawrence** supported the Bill as a step in the right direction, and Mr. **Emmott** spoke in the same sense.

Colonel **Sadler** took the view that all that was wanted was trained nursing under medical supervision.

Mr. L. **White** gave general support to the Bill, while admitting that it must be considerably altered in committee.

Sir **Walter Foster** said that the subject was one that required deliberation on the part of men specially qualified to consider it, and it was a problem which even then would be very difficult of solution. He was, however, glad that the only thing which they differed about was the question of method, and in his opinion this Bill was not as good a Bill as those which had preceded it. It must be remembered that they were dealing with a subject which had been steadily growing in complexity during the past 40 years. No man was allowed to practise midwifery unless he had had five years' training and had obtained a diploma, so that if he (Sir Walter Foster) happened to be a general practitioner and wanted assistance in midwifery cases he could not get assistance from a pupil who had been five years in the medical schools and was perfectly qualified in every way except in having still to pass the final examination. He could not employ such a man to attend the simplest cases of labour. That was a very strong position for the law to take up, but it was the law as laid down in 1886. It was so strong that the General Medical Council had actually accused medical men of infamous conduct for employing men who were undoubtedly good at midwifery cases because these assistants were not qualified to go on the Medical Register. That attitude was taken, not in the interests of the medical profession, but entirely to save the public from the terrible diseases and suffering that they had experienced in the past at the hands of illegal and unqualified practitioners. The medical profession had been exceedingly zealous in maintaining a high standard of medical aid for the poorer classes; but if this Bill were passed in its present form all the structure that had been built up with great care in order to protect the public from the unqualified practitioner would fall to the ground. The Bill would not touch the worst cases—the cases of people in country districts and manufacturing towns who did not put out any brass sign but who had their own little connexions amongst people. The only people the Bill would touch were the certificated midwives who did at present undergo a certain amount of training, and the Bill would create practically a new class of practitioners. Although he was entirely in favour of something being done he could not vote for this Bill because it fell short of previous attempts. There would be no adequate supervision—it would be an enormous advantage to obtain licences from a local authority; they had not local control; there was no sensible medical control, for the General Medical Council was practically struck out of the Bill. Nor did he like the central authority. One of the representatives was to be from a body which was not known in his profession—namely, the Incorporated Midwives Institute. It was not strong enough for controlling tens of thousands of women all over the country. But he believed that the right course would be to refer the Bill to a select committee, because it was not a measure that could be discussed adequately in a full committee of the House or by a grand committee. The problem was too big to be in the hands of a private Member, it ought to be taken up by the Government; and in this connexion he suggested that the Home Secretary should consider a Bill for the registration of all nurses.

Mr. **Heywood Johnstone** said that the honourable gentleman who had just spoken had never done anything himself to help to solve the problem. It had been argued by some speakers that the Bill was defective in that instead of the licensing proposed in the Bill of 1900 a system of notification was inserted. The object was to provide for local supervision which they all believed to be important and necessary. Certain women had felt that it was a humiliation to take out a yearly licence, and therefore an effort had been made to meet the objection by substituting a much less harassing system—namely, that they should simply give notice of their intention of practising and of the fact that coroners. The evidence which the coroners had given them was of such a nature that if it could be printed and circulated among Members of the House it would convince the House of the absolute necessity of some such legislation as was now proposed.

Sir JOHN TUKE said that it was with a certain amount of regret that he moved the rejection of this Bill. It contained certain good points, but the Bill was so lacking in strength and purpose that he considered it to be really a useless measure. It was lacking in one essential and vital point, and on account of that he conceived it to be his duty to move its rejection. He supported the Bill of 1900 generally on the ground that, to his mind, it was an important measure bearing upon public health. He supported it notwithstanding the opposition of a section of the medical profession. The profession was by no means unanimous upon the question, but he thought as regards the present Bill he was not wrong in saying that 95 per cent. of the medical profession would oppose it on account of the omission of the penalty clause. The hon Member had spoken of the attitude of the General Medical Council as being that of the dog in the manger. That was not so. He spoke in 1900 in order to represent the views of the General Medical Council, which was as desirous as he was that a really good and efficient Bill should be presented to the House. He supported the Bill of 1900 on account of the strong belief held that it would confer very great benefits upon parturient women, but the measure now before the House did not contain the clause which rendered the Bill of 1900 an important measure of public health, and the omission of that clause rendered this Bill in his opinion inoperative, futile, and to a certain extent mischievous. It omitted the provision to prevent uncertified women from practising and to his mind this omission constituted a cardinal objection to the Bill. He opposed it on this ground, though of course he had other grounds of objection. It had been said that the great object of the Bill was to provide women in labour with suitable and safe attendance. There was no one more anxious than he that a measure securing this object should pass, but it could only be secured, not merely by providing for the education and superintendence of midwives, but by a measure preventing the practice of incompetent women. It was a matter of common knowledge that amongst the women who acted as midwives there were a considerable number who, by their ignorance, carelessness, filth, and dissipated habits, constituted a serious danger to the public. Through their evil ways puerperal fever was generated and communicated from case to case. That most dangerous form of insanity spoken of as puerperal insanity was often engendered and many hundreds and thousands of women suffered for years from the consequences of ill-directed labour and not a few cases of death to mother and child occurred. For evidence of this it was only necessary to refer to the verdicts found in coroners' courts. The Bill of 1900 was not only calculated to build up a new class of midwives who after receiving an elementary education in obstetrics would be placed as to their practice under regulation and supervision, but by a special clause it was calculated to suppress the existing dangerous class. The present Bill failed in this most important particular. It did not suppress the evil out of which the movement for the registration of midwives arose. Under the Bill of 1900 only certified women were allowed to use the name "midwife," and, what was of infinitely greater importance, uncertified women who habitually and for gain practised midwifery were made liable to a fine not exceeding £5. According to Clause 3 of this Bill any woman who within two years from the date of the Act coming into operation claimed to be certified would be so certified provided she held a certificate in midwifery from the Royal College of Physicians of Ireland or the Obstetrical Society of London or such other certificate as might be approved by the Central Midwives Board, or produced evidence satisfactory to the Board that at the passing of the Act she had been in *bonâ-fide* practice as a midwife and that she bore a good character. Thus any woman who now acted as a midwife could obtain certification upon producing evidence that she was a respectable woman and fulfilled certain conditions laid down by the Central Midwives Board. Surely this was a sufficient protection of vested interests. By this clause only ignorant, disreputable, or incompetent persons would be precluded from certification—the very class of persons out of whose irregularities the whole question had arisen. As the Bill stood this class of persons would be allowed to continue their work unchecked by any authority or by any form of supervision. It was quite true that they could not put a notice-board over their doors or a ticket into their windows intimating that they were midwives, but these were small disabilities which would have no effect in the way of checking their practice. In spite of this Bill they would continue to be a source of danger and of disease. It might be argued that already the number of incompetent women was diminishing, consequent upon the extended views upon nursing generally, but evidence obtainable from the great manufacturing centres, from the metropolis itself—evidence obtainable from district nurses, Queen's nurses, and others—showed that at the present moment the dangerous midwife was still a power in the land. He would like the House to consider whether the provisions of this Bill were likely to lessen the number of uncertified midwives. They might produce a class of fairly well-educated women, educated in the rudiments of obstetrics and the first principles of cleanliness; but before a woman could get on the register she came under the jurisdiction of the Central Midwives Board, one of whose functions was to regulate the course of training and conduct of examinations of candidates. This Board would admit to the roll any woman who had had a certain amount of training, which in his opinion would be an absolutely unappreciable benefit. According to Clause 8 the midwife was placed under the immediate supervision of the county or district council and she had to pay fees. All that she got in return was the right to call herself "midwife" and to sue for fees, while alongside of her was a woman who paid nothing and was free from all authority. There was power to strike a woman off the roll for misconduct, but what did that matter? she could still go on practising. He believed that the promoters of the Bill were sincerely sorry when under the pressure of certain permanent officials they withdrew the penal clause and thereby absolutely eviscerated the Bill. It was said that the penal clause would create a new class of offence. He denied that. There was the Apothecaries Act of 1815 which was not repealed and indeed was constantly put in force. There was the case of solicitors and auctioneers and traders, and, as an hon Member suggested, the case of the man who carried the gun. These were precedents; why not apply them to midwives? It would not be the creation of a new offence, but only the extension of an existing principle of law to a dangerous class. His own opinion was that the certified midwife would be in the minority. He had not argued the case from a professional point of view; he had done so from the point of view of a member of the general public. He held no brief for the medical profession. If he held a brief at all it was for the hundreds of thousands of women who either from necessity or choice were attended by midwives. He would gladly support this Bill, with, perhaps, some modifications, were the penal clause he had alluded to introduced, but as an old Parliamentary friend had said to him, "You can never make certain of anything in this House," and therefore he found it necessary to press his amendment. He did so on the ground that this was not a measure calculated to secure public health, that it was futile, and that it did not secure the advantage to lying in women which its promoters had in view.

Sir BARRINGTON SIMEON said that he had no professional knowledge of this subject, but he happened to own land, and as a land-owner he knew that if midwives were given a certain amount of authority in the eyes of poor people because they were called "certified" or "registered" there would be far more danger of illegal operations being performed on young girls in trouble and on married women who did not wish to increase their families. This was a point which he thought should be considered before Members voted for the second reading of this Bill. In his opinion the Bill would create a new class of midwife who would be employed as a substitute for the medical practitioner. He admitted that the present state of things was unsatisfactory, but his view was that this measure would not improve it. No Bill could be satisfactory which must create trouble between local medical men and midwives.

Dr. R. FARQUHARSON said that there had been no more effective speech made yet in favour of the Bill than that by Sir John Tuke who, although dissenting from certain of the propositions, had given a most plain and practical testimony as to the great evils which were going on throughout the country, and had thrown in his lot with those who desired to find some remedy for a condition of things which taken the greatest interest in the matter for many years. They all of them had the desire that this Bill should pass, although many of them thought that it did not go far enough. He hoped that the House would give the Bill a second reading and send it to a tribunal which would deal with it without delay and enable the measure to become law during the present session.

Mr. Caine asked the promoters to make clear whether the body mentioned in Clause 4 was the Incorporated Midwives Institute. He knew of no such institute; he had asked for information about it but he had got none. Indeed, he did not believe that any such institute was in existence.

Mr. Heywood Johnstone replied that it was a body which had been in useful existence for a considerable number of years. The House might be quite certain that it would not have got its charter of incorporation from the Privy Council, from which it would necessarily come, unless it were a responsible body and a body engaged in doing good work.

The amendment for the rejection of the Bill moved by Sir John Tuke was negatived without a division, and thereafter the motion for the second reading was agreed to, also without a division.

Mr. Heywood Johnstone moved that the Bill be referred to the Grand Committee on Law.

Sir Walter Foster moved as an amendment that it be referred to a select committee. He argued that this form of committee would give the Bill a more thorough examination than could be given to it by the Grand Committee.

Sir John Tuke seconded the amendment.

Mr. T. P. O'Connor, supporting the amendment, said that he had no thought of meeting the Bill in a spirit of malignant or obstructive criticism, because he approved its principle; but while that was so he remembered the proceedings in the Grand Committee before and he could not conceive a more uncompromising person than Mr. Heywood Johnstone during these proceedings. The hon. Member had got this Bill so much upon his mind that he regarded anyone who offered any criticism upon it as breaking some sacred or Divine law and he doubted whether on this occasion he would get very much consideration from the hon. Member in the Grand Committee. His own view was that it would not be against the passage of the Bill if it were referred to a select committee.

Mr. Heywood Johnstone said that he had served on many select committees, and not one of the Bills which had been considered by them had been placed on the statute-book. He therefore opposed the idea of a select committee in this case.

Mr. Griffith Boscawen spoke in favour of reference to the Grand Committee.

As in the former case, the amendment was not pressed to a division.

The Bill accordingly was referred to the Grand Committee on Law.

# THE METROPOLITAN WATER-SUPPLY.

## II.[1]

### The Lambeth Waterworks Company: Some Questions for the President of the Local Government Board.

The arrangements of the Lambeth Waterworks Company are unsatisfactory in more than one respect.

1. There is a deficiency of reservoir capacity.
2. The filtration area is insufficient.
3. Constant water service is not given to all those who have the right to demand it.

1. It is a matter of common knowledge that years ago the ordinary water of the Thames was used as a beverage. At the present time, however, it is not generally looked upon as suitable for that purpose. It is true that before the Llandaff Commission Professor Dewar, F.R.S., in giving evidence on behalf of the metropolitan water companies, said (Jan. 17th, 1899) that he would not object to drink unfiltered Thames water. But there are men who are employed to drink sewage effluents to prove their purity. It is not necessary to dwell on this matter. It is well that people should weigh the facts for themselves. At the present time the metropolitan water companies are not allowed to supply crude river water for human consumption. The chief means adopted for its purification are sedimentation and filtration. The Water Examiner in his last annual report (1900–1901) explained to the President of the Local Government Board the utility of storage reservoirs. It may be worth while to quote these remarks, which are to be found on page 247 of the Thirteenth Annual Report of the Local Government Board: "The fact that the impurity of the water in the rivers is so largely increased during periods of flood renders it of great importance that there should be sufficient provision of subsidence and storage reservoirs to enable the necessary daily supplies to be delivered during such periods, while keeping the intakes closed. Such provision is essential for securing uniformly effective filtration. The area of the available filters should also be sufficiently large to enable the necessary supply to be collected when the passage of the water through the material is sufficiently slow effectively to filter the worst water which circumstances may render it necessary to deal with." It is instructive to compare the relative reservoir capacity of the West Middlesex Waterworks Company with that of the Lambeth Company. In taking the West Middlesex Company as a standard of comparison it is not to be assumed that the arrangements of that company are perfect or that the water supplied by them is of ideal quality. It is not. Excellent water is supplied by the Kent Company. The customers of the New River Company have rarely cause to complain. Of the other companies the arrangements of the West Middlesex Company are the best. It happened that when the company not only paid its full statutory dividend and had also paid its back dividends, it was discovered by the directors that new works were required to ensure thorough efficiency. This discovery synchronised ("by some odd coincidence," as Lord Llandaff put it[2]) with the last payment of the back dividends. Improvements were then, in fact, effected in the company's works, and as far as the shareholders' pockets were concerned there was no reason why these should not be done. The undertaking indeed was brought to a state of comparative efficiency, although not to a state of such efficiency as to secure a supply of water equal in quality to that of the New River Company. The Lambeth Company has been less fortunate, as a business concern and the old works have remained much as they were. The table given below, which is compiled from the December report of the Water Examiner, shows the average daily amount of water supplied during the month, the estimated population served, the storage reservoir capacity, and the filtration areas of the West Middlesex Company and the Lambeth Company respectively.

| — | Daily average amount of water supplied in gallons. | Estimated population. | Storage reservoirs. | | Filter-beds, area in acres. |
|---|---|---|---|---|---|
| | | | Area in acres. | Capacity in gallons. | |
| West Middlesex ... ... | 20,565,429 | 650,754 | 117½ | 397,500,000 | 22¼ |
| Lambeth ... | 26,168,039 | 764,481 | 31 | 128,000,000 | 12¼ |

It is evident at a glance that although the amount of water which is distributed by the Lambeth Company is greater than that which is distributed by the West Middlesex Company, the reservoir capacity of the Lambeth Company is less than one-third of that of the West Middlesex Company. The figures, as given in the Water Examiner's report, show that whereas the West Middlesex Company has a storage capacity sufficient for the wants of its customers for a period of 18·7 days the Lambeth Company has sufficient for only 4·9 days. Enough has been said to show that the Lambeth Company is deficient in its reservoir capacity.

2. The filtration area is insufficient and in the case of the Lambeth Company the offence is the more serious because the storage reservoirs are deficient in capacity. Water which has undergone a prolonged process of sedimentation becomes comparatively pure, the filter-beds have therefore less work to do. When, therefore, a water company has a reservoir capacity insufficient to ensure a sedimentation of the impurities of the river water it becomes the more necessary that the filtration area shall be ample. It cannot be too strongly insisted upon that the smaller the sedimentation

---

[1] Article I. appeared in The Lancet of March 1st, 1902, p. 614.

[2] Feb. 14th, 1899. Fifty-second sitting of the Llandaff Commission.

they were practising. There was nothing which impaired the power of local supervision which local authorities were given in the Bill of 1900. These authorities would still have the power of general supervision, of investigating charges of malpractice, negligence, or misconduct, and of supervision, if necessary, and they would be able to keep their finger on the women practising in their area, without being unduly harassing. The main objection taken to the Bill was that it did not contain the words rendering unqualified practice illegal. The Bill gave to the person who needed the services of a midwife the power of discriminating between the women who were qualified and those who were not qualified, but, unlike the Bill of 1900, it did not absolutely penalise unqualified practice. It was impracticable to do such a thing, and he hoped that he was committing no breach of confidence when he said that the promoters had had information from high quarters that it would be hopeless to attempt to carry any measure at all if they encumbered it with a clause penalising unqualified practice. He was quite aware of the views of the General Medical Council on this point, but the promoters realised, and the Council realised, that the point was contended for as a stepping-stone towards rendering the practice of unqualified medical men absolutely penal. That had been the Council's aim and desire for a long time. It might be a very wise object, but at the present time the promoters had to consider what they could get in the Bill, and if they got even this Bill in its existing state they would do much to solve the difficulty. They were treading a somewhat unknown path, and until they had had experience of the working of this particular measure it was extremely undesirable that they should lay down, say, a hard-and-fast rule for so many months' training. All these things were better provided for in the end by rules which could be modified as experience suggested. He believed that when they came to thresh out the details they would find that there were more points of agreement than of difference. In conclusion, he mentioned that he had received a number of instructive figures dealing with the deaths of women attended by trained midwives sent out from some of the large hospitals and institutions. Out of 13,712 cases attended the deaths were only 17—a death-rate of 1·23 per 1000 as compared with a general death-rate in maternity cases of 4 66 all over the country. No other argument was necessary to show the superiority of the trained over the untrained midwife.

Mr. T. P. O'CONNOR, after describing himself as not an opponent of the Bill, but a vigilant critic of it, said that he objected in principle to the multiplication of registered bodies and expressed the view that the cry of "something must be done" had often led to unwise legislation. His contention was that women must not be allowed powers of practising medicine under less severe guarantees and safeguards than were applied to men.

Sir SAVILE CROSSLEY approved the Bill as a measure calculated to do good among the poorer classes of the community.

Sir MICHAEL FOSTER said that childbirth was sometimes spoken of as a travail, and it might be likened to a journey through which one might go with the ordinary discomforts of travel. It was a journey fraught with the utmost peril to life. Those who could afford it were able to carry a medical adviser with them so that he could be there whenever an accident occurred. But the poor could not do that, and as he understood this Bill it was designed in the interest of the poor in order that they might carry with them on this perilous journey, not a medical man, but one who knew when a medical man should be sent for. If he understood the object of the Bill it was simply to arrange that the public might know that there were special nurses different from the ordinary trained nurses. The main qualifications of these special nurses were, first, to know when to send for a medical man; second, to be cleanly and to know what cleanliness meant; and thirdly, never to drink. His interpretation of the Bill was that it simply demanded this and he looked with terror on any proposal requiring two or three years' training in an obstetric school. In his opinion it was far better for the House to throw itself upon the good feeling and the knowledge of the people than to trust to the enforcement of penal clauses. When the people knew that Mrs. Gamp could be trusted and that Mrs. Harris could not be trusted, even if Mrs. Gamp charged a shilling more than Mrs. Harris, he ventured to say that Mrs. Gamp would prosper and Mrs. Harris would disappear because she would be starved out of existence.

Mr. JOHN BURNS said that he had consulted medica practitioners in his constituency of Battersea on thi subject as well as the sisterhood of nurses, and he ha found that they viewed this legislation with sympathet consideration and support. If Members had any fear th the Bill would lead to a lowering of the standard medical education or any laxity on the part of medical pra titioners they might dismiss the thought. They might leave that question entirely in the hands of the medical men who in such a matter were thoroughly well able to take care of themselves. He had a great admiration for medical men. The medical man was usually the very best man in the parish, he did more unpaid work than any professional man he knew and more for the poor. He did not believe that Parliament need have any fear about the standard of medical education being lowered, but he did believe that if they had qualified midwives as they had qualified nurses many children would be born into the world better able to fight its battles and many women would be spared suffering and death. In his opinion all the objections to the Bill were objections in details which would properly be discussed before a committee.

Mr. RITCHIE said that there seemed to be a general consensus of opinion in the House in favour of the second reading of the Bill. Indeed, the only speech that he had heard which attacked the Bill root and branch was the speech of Sir Walter Foster who desired the House to take refuge in that familiar mode of getting rid of a subject which anyone wished to see shelved—namely, to ask the House to have more inquiry into the matter before dealing with it The hon. Member really answered himself, because he told the House that there had been inquiry after inquiry upon Bill after Bill with regard to this subject and that Parliament had never got beyond inquiry. What was the reason why a principle which all were agreed upon had not yet got to the stage of effective legislation? It was because a certain number of gentlemen who were not opposed to a change in the law desired something much more than anything suggested in this Bill. More inquiry was wanted in order to make the Bill more drastic, more comprehensive, more complete. He ventured to say that these were the wrong lines altogether to go upon in this matter. They were all agreed that a great evil existed That great evil was the fact that no person requiring the attendance of someone to help during this time of peril knew whether the woman who was called in was qualified to meet the difficulties of the situation. This wa a modest Bill. It proposed to place at the service of every body who required assistance of this kind the knowledg which would enable them to judge whether or not the person they called in was, a person who might be trusted. He knew that there were some people who desired to go very much further and to say that the person who was called in must go through a very long course of training. That would mean that in a large number of towns and villages the poor would be deprived of all assistance of this kind. They would not be able to avail themselves of anything but the assistance of a medical man, which would be beyond the means of many, and besides the medical man might not be at call when wanted. Much more than expert knowledge was required at times such as these, and to pass a measure which would be so drastic as to prevent the poor being able to avail themselves of this assistance at the time of need would, in his opinion, be an unfortunate thing to do. There were matters of detail with regard to this Bill which might very well be considered in committee, but there were two perils which faced the House if it desired the Bill to pass. One peril was a select committee. It might be taken for granted that a select committee would, at any rate for the present session and probably for many sessions to come, be the grave of this Bill. There was another peril and that was the effort, well-meaning effort, to make the Bill very stringent. If an attempt was made to alter the Bill from the simple Bill which it was now to a complex Bill that again would prove the grave of the Bill. In this measure they had a simple remedy, with nothing heroic about it, for what everybody admitted to be a great evil Let them not refuse to take this because it did not go the whole length which some of them desired. It had been very carefully considered by his hon. friend who had devoted so much time and attention to it and by large numbers of ladies and gentlemen who had

In accordance with notice given it was moved by the PRESIDENT and seconded by Dr. WILLIAM JAQUES—

> That any medical man who shall knowingly meet in consultation any practitioner who is actively opposed to the union shall himself be considered as opposed to the union.

This motion was carried unanimously.

It was also resolved on the motion of the PRESIDENT, seconded by Mr. E. H. DAVIS—

> That in the opinion of the union the payments made by insurance companies for medical examinations are totally inadequate.

Considerable discussion on the subject then took place and it was resolved—

> That the subject of the payment of fees for examinations for life assurance be referred to the various local committees for consideration and report to the Council, and that after such reports have been received communication be opened with the Northumberland and Newcastle Medical Association with a view to concerted action in the counties of Durham and Northumberland.

It was ordered that copies of a table prepared by the secretaries of the fees at present paid by certain life assurance companies should be printed and supplied to the local committees.

Dr. MANN drew attention to the exorbitant rates of commission charged at some collieries for the collection of the fortnightly payments to the medical officers, and after some discussion, in which it appeared that the rate varied from 5 to 10 per cent., whilst at some collieries no commission at all was charged, the following resolution was passed:—

> That the attention of owners and managers of collieries and works in the county be drawn to the exorbitant rate of commission charged at some places for collecting doctors' subscriptions from workmen with a recommendation that where charged at all the rate should not exceed 5 per cent.

A discussion took place in reference to the difficulty experienced by practitioners in obtaining serum rapidly and suggestions were made that it should be supplied gratuitously, and on the motion of Dr. MANN, seconded by Mr. E. H. DAVIS, it was resolved—

> That taking into consideration the great danger to the public health and the difficulty of procuring serum rapidly sanitary authorities be urged to supply serum to medical practitioners gratis or at cost price at the discretion of the medical officer of health.

Dr. ARMSTRONG raised the question of the additional and important duties which had devolved on medical men in connexion with cases under the Workmen's Compensation Act, and drew special attention to the fact that as a rule no payment was made to the colliery surgeons for attending post-mortem examinations and consultations on behalf of the owners, and, on the motion of Mr. E. H. DAVIS, seconded by Dr. COX, it was resolved—

> That some representation be made to the Durham Coal Owners' Association and to the owners of collieries and works asking that a fee be paid to colliery surgeons for attending post-mortem examinations and consultations on their behalf.

A hearty vote of thanks to the President terminated a very interesting and successful meeting.

The members subsequently dined together at the Grand Hotel, Sunderland, the Mayor of Durham (Mr. R. T. Herring, J.P.) being one of the guests.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8455 births and 6633 deaths were registered during the week ending March 1st. The annual rate of mortality in these towns, which had been 20·6, 22·6, and 24·4 per 1000 in the three preceding weeks, declined again last week to 23·3 per 1000. In London the death-rate was 28·2 per 1000, while it averaged 21·1 per 1000 in the 75 other large towns. The lowest death-rates in the 76 towns were 10·6 in Aston Manor, 11·7 in Hornsey, 12·4 in Walsall, 12·6 in Leyton, 12·9 in Kings Norton, and 13·8 in Norwich; the highest rates were 27·3 in Great Yarmouth, 27·6 in Reading, 28·2 in London, 28·5 in St. Helens, 28·8 in Merthyr Tydfil, 29·3 in Hastings, and 29·4 in Plymouth. The 6633 deaths in these towns last week included 570 which were referred to the principal zymotic diseases, against 584, 525, and 581 in the three preceding weeks; of these 570 deaths 166 resulted from measles, 122 from whooping-cough, 90 from diphtheria, 84 from small-pox, 45 from scarlet fever, 34 from diarrhœa, and 29 from "fever" (principally enteric). No death from any of these diseases occurred in Hornsey, Bournemouth, Ipswich, Great Yarmouth, Burton-on-Trent, Handsworth, Birkenhead, Middlesbrough, or Sunderland; while the highest zymotic death-rates were recorded in Willesden, Tottenham, West Ham, Burnley, Huddersfield, and Stockton-on-Tees. The greatest mortality from measles occurred in Willesden, Tottenham, Brighton, Southampton, Northampton, Burnley, Huddersfield, and Rotherham; from scarlet fever in Wigan; from diphtheria in Willesden, Coventry, and West Hartlepool; from whooping-cough in Aston Manor, Wallasey, Liverpool, York, and Gateshead; and from "fever" in Devonport. 75 fatal cases of small-pox were recorded in London last week, seven in West Ham, one in Tottenham, and one in Swansea. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1102, 1185, and 1321 at the end of the three preceding weeks, had declined again to 1309 on Saturday, March 1st; 379 new cases were admitted during the week, against 287, 390, and 502 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2307, against numbers decreasing from 3137 to 2413 on the nine preceding Saturdays; 215 new cases were admitted during the week, against 277, 260, and 219 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 486, 681, and 885 in the three preceding weeks, declined again last week to 733, but were 203 above the average. Influenza was stated to be the primary cause of 103 deaths in London last week, against 40, 51. and 107 in the three preceding weeks. The causes of 92, or 1·4 per cent., of the deaths in the 76 towns last week were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Bolton, Bradford, and in 37 other smaller towns; the largest proportions of uncertified deaths were registered in Smethwick, Liverpool, St. Helens, Blackburn, Barrow-in-Furness, Sheffield, and Sunderland.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·6 and 25·3 per 1000 in the two preceding weeks, declined again to 22·6 per 1000 during the week ending March 1st and was 0·7 below the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17·3 in Paisley and 18·5 in Aberdeen to 24·2 in Greenock and 26·3 in Dundee. The 729 deaths in these towns included 23 which were referred to whooping-cough, 19 to measles, 13 to diarrhœa, 10 to small-pox, five to "fever," four to scarlet fever, and one to diphtheria. In all 75 deaths resulted from these principal zymotic diseases last week, against 66 and 81 in the two preceding weeks. These 75 deaths were equal to an annual rate of 2·3 per 1000, which was 0·3 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 20 in each of the two preceding weeks, rose last week to 23, of which seven occurred in Glasgow, seven in Aberdeen, five in Edinburgh, and three in Paisley. The deaths from measles, which had been 12 and 17 in the two preceding weeks, further increased to 19 last week, and included six in Glasgow, six in Dundee, three in Edinburgh, and two in Greenock. The fatal cases of diarrhœa, which had been 23, 16, and 22 in the three preceding weeks, declined again last week to 13, of which five were registered in Glasgow, four in Dundee, two in Aberdeen, and two in Paisley. The deaths from small-pox, which had been one, two, and seven in the three preceding weeks, further rose to 10 last week, and were all recorded in Glasgow. The fatal cases of "fever," which had been 10 and six in the two preceding weeks, further declined last week to five, of which two occurred in Glasgow, where the four deaths from scarlet fever were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 173, 211, and 224 in the three preceding weeks, declined again last week to 214, but exceeded by 30 the number recorded in the corresponding period of last year. The causes of 24, or more than 3 per cent., of the deaths in these eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·8, 25·7, and 33·3 per 1000 in the three preceding weeks, declined again to area is the larger the filtration area must be to ensure the removal of foreign matter. The Lambeth Company, as we have seen, is not only deficient as to its reservoir capacity, but the filtration area is very inadequate. Whereas the West Middlesex Company has a filtration area of 22¼ acres to treat something under 21,000,000 gallons of water daily, the Lambeth Company has only a filtration area of 12¼ acres in which to treat over 26,000,000 gallons daily. During the month of December, 1901, according to the monthly report of the Water Examiner, "the water of the Lambeth Company exhibited the deepest average tint of brown." The brown tint is observed by looking through the water contained in a two-foot glass tube; it represents foreign matter or dirt and is usually said to be chiefly of vegetable origin. The brownish tint which is to be observed in Thames flood water is familiar to most people. It is some of this matter which is distributed by those of the metropolitan companies which do not adequately treat the river water by the methods of sedimentation, or filtration, or sedimentation and filtration.

Dr. Thorpe, the analyst to the Local Government Board, reported that on Dec. 30th last the Lambeth Company's water was "very faintly opalescent," and that it "contained a considerable amount of organic impurity." Taking the average amount of organic impurity in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by the Lambeth Company on Dec. 9th last was 2·4—that is to say, nearly two and a half times greater. On Dec. 30th, 1901, the amount was 5·3—that is to say, more than five times the standard, and no less than double the amount contained in the water distributed by the company on Dec 9th. How is this to be accounted for? The answer is not doubtful. The problem may be solved in the light of what has been said and by a study of a table given in the Water Examiner's report for December, 1901 (page 4) Daily observations on the state of the Thames water are made by the engineer of the Chelsea Company and these records are given in tabular form. The facts are these: From Dec 1st to the 12th the state of the river water was good, on the 13th it was indifferent, from the 14th to the 17th it was bad, and on the 18th and again on the 25th it was indifferent. From the 26th to the 30th it was bad. It is evident that the present arrangements of the Lambeth Company in regard to sedimentation and filtration are so defective that in a period of flood the water distributed becomes brownish in colour and that the amount of organic carbon which it contained is more than doubled.

3 Constant service is not given to all those who have a right to demand it. In December, 1901, four of the metropolitan companies professed to give constant service to all their customers; and of the supplies given by the other companies, the Kent, the New River, and the Southwark and Vauxhall companies gave constant service to 95 9 per cent, 95 7 per cent, and 93 per cent. of their customers respectively. The Lambeth company gave constant service to only 77 5 of its clients

Has the attention of the President of the Local Government Board been called to the fact that it is of great importance that the metropolitan water companies should possess subsidence and storage reservoirs having a capacity sufficient to enable them to secure uniformly effective filtration?

Has the attention of the President of the Local Government Board been called to the fact that in December, 1901, during a period at which the Thames was in flood, the Lambeth Waterworks Company distributed water which was of brownish colour and which contained more than five times the amount of organic impurity of that of the "standard" adopted by the Water Examiner to the Local Government Board?

Has the President of the Local Government Board communicated with the Lambeth Company on this matter or taken any steps in regard to it? If so, with what results?

Is the President of the Local Government Board aware that less than 78 per cent. of the customers of the Lambeth Company have constant water service?

---

NOTIFICATION OF CHICKEN-POX.—On Feb. 24th the Yeovil Rural District Council resolved that chicken-pox should be added to the list of notifiable diseases.—The Radstock (Somerset) Urban District Council arrived at a similar decision on Feb. 26th.

---

# COUNTY OF DURHAM MEDICAL UNION.

THE half-yearly meeting of the members of this union was held in the Town Hall, Sunderland, on Feb. 11th last, Dr. EDWARD JEPSON (Durham), the President, being in the chair. There was a large attendance of members, amongst those present being Dr. James Murphy (Sunderland), the Vice-President; Dr. J. F. Armstrong (South Shields), Mr. J. Arthur (Wingate), Mr. A. W. Attwater (Whickham), Dr. J. Charles (Stanley), Dr. Alfred Cox (Gateshead), Dr. A. Holdsworth Davis (Sunderland), Mr. E. H. Davis (West Hartlepool), Mr. W. H. Davis (Low Fell), Dr. E. W. Diver (Shotley Bridge), Mr. W. Galloway (Low Fell), Mr. A. T. Harrison (Sherburn Colliery), Dr. W. Hay (Sunderland), Dr. John Hern (Darlington), Mr. K. O. Hill (Jarrow), Dr. R. S. Hubbersty (Sunderland), Mr. A. S. Jaques (Gateshead), Dr. William Jaques (Washington), Mr. A. E. Legat (Sunderland), Mr. J. W. Mackay (Pelaw), Dr. Charles F. G Mann (Washington), Dr. L. S. F. de R. Norman (Jarrow), Dr. N. F. Rowstron (Sunderland), Dr. A. Smith (Whickham), Dr. J. W. Smith (Ryton-on-Tyne), Mr. Robert Stuart (Durham), Dr. John Taylor (Chester-le-Street), Mr. D. F. Todd (Sunderland), and Mr. James Waterston (Sunderland).

The PRESIDENT opened the meeting by intimating the receipt of letters from several members who were unable to be present and then he referred to the fact that since the annual meeting the union had lost two of its members by death—namely, Dr. D. Wingate (Easington) and Dr. A. Reid (Blackhill), the latter under very painful circumstances. [Mr. J. ARTHUR of Wingate, interposing, mentioned that a third member, Dr. W. Nesbitt of Thornley, had recently died.] The President further stated that with a view to increase the membership every practitioner in the county had been invited to the present meeting, and he hoped that if any strangers should happen to be present they would feel that they were cordially welcome.

On the motion of the PRESIDENT, seconded by Dr. ARMSTRONG, votes of condolence with the families of Dr. Wingate, Dr. Reid, and Dr. Nesbitt were passed unanimously.

Dr. James Boyle (Fencehouses), Dr. W. G. Thompson (Sunderland), and Dr. W. G. T. Mecredy (Nettlesworth) were elected members.

The treasurer's statement to date showing a balance of £72 16*s.* 4*d* was submitted and adopted, and a balance of £52 18*s.* due to the secretaries was ordered to be paid.

A report of the Council was read and reports were made by representatives from the districts of Stanley, Chester-le-Street, Sunderland, Jarrow, Hartlepool, and Darlington. Some discussion then took place upon the motion adopting the reports of the Council and local committees, in the course of which Dr HERN stated that the Darlington practitioners had recently made a request to the friendly societies of that town for the payment of 4*s.* per member and 2*s.* for juveniles and asked for some guidance as to the steps which should be taken in the event of a refusal to agree to the demand. The feeling of the meeting was that each local district should deal with this question in the way and when it thought best, but that the minimum fee for adults must be 4*s.* per member, and many members were averse to any lower rate being accepted even for juveniles.

Dr. COX (Gateshead) made a report as to the meeting with the Direct Representatives on the General Medical Council held in Newcastle-upon-Tyne on Oct. 26th, 1901, which he thought would be productive of good, and a vote of thanks was accorded to him for his services in connexion with the matter.

After further discussion the reports were adopted, and it was resolved, on the motion of Dr. ARMSTRONG, seconded by Dr. MANN, that the report of the Council, which contained several interesting items, should be printed and circulated.

Reference having been made to the alleged employment of unqualified assistants by members it was resolved on the motion of Dr COX, seconded by Dr. MURPHY—

> That any member known to have in his employment an unqualified assistant be warned that the matter will be reported to the General Medical Council and that it will be the duty of the union in the interest of the profession to take the same steps as would be taken in the case of a non member.

prescribing poisonous and powerful drugs under any circumstances, especially in such huge doses and to a woman not responsible for her actions.

4 Mr. Bankes attempted, but most miserably failed, to connect me with an attempt to entrap Dr. Law into a consultation with the family solicitor. I need hardly do more than deny that; it is such an absurd allegation and so absolutely without foundation, and with the evidence before him a very unjustifiable thing for a man like Mr. Bankes to attempt

Dr. Law and I were perfectly friendly; our meeting was friendly, our parting was friendly. After the consultation I expressed to him when shaking hands a hope that all would be settled satisfactorily. Dr. Law himself asked me to accompany him to the house I did so. At the door of the house I was asked to come in to the interview. I did so. I took no part or interest in the interview; it was no business of mine. I did say Dr Law's prescriptions were, to my mind, very injudicious, but "fishy" is a word I never used I had no possible reason for being antagonistic to Dr. Law any more than I had for being the contrary to Miss Forsythe. The whole thing has been most distasteful and hateful to me, but, in my opinion, I could not act in any other way than I did. And I absolutely deny any and all the allegations made against me by Mr. Bankes. I am sorry to have written at such length, but I think this explanation necessary.

I am, Sirs, yours faithfully,

Ladbroke-square, W., March 1st, 1902. JAMES KIRKLAND.

## THE STUDY OF THE HISTORY OF MEDICINE.

*To the Editors of* THE LANCET.

SIRS,—In the *British Medical Journal* of Nov. 23rd, 1901, it was suggested by Dr. M. G. Biggs that a society should be formed for the study of medical history, and in the following issue Dr. D. C. Lloyd-Owen uttered a further plea for the inclusion of the subject in the medical curriculum.

Having allowed a considerable interval to elapse it became apparent upon inquiry that nothing further had been done in the matter, and since the acceptance by the Royal College of Physicians of London of the FitzPatrick endowment of a lectureship of medical history had excited a quite unusual amount of interest in the subject it seemed to me a mistake to allow such an opportunity to pass.

In this spirit I ventured to bring the suggestion to the notice of several of those whose names—by authorship or otherwise—have become associated with the subject, and the scheme has already met with the approbation and support of Dr. J. F Payne, Dr. W. H. Allchin, Professor A. Macalister, Mr. D'Arcy Power, Mr. Charles Williams, Dr. E. T. Withington, Dr Lloyd-Owen Dr. Arthur J. Hall, Dr. J. Stokes, Dr. Biggs, and Dr. A. H Robinson.

It has been objected by some that there are already so many societies that it is doubtful whether there is room for another; that their multiplication tends to starve existing ones; and that the subject might well be discussed in any of these. But in spite of the quarter whence these objections come I am by no means convinced of their soundness.

With reference to the first objection, I am hopeful of its being practically refuted by succeeding in the endeavour to form a society similar in its objects to that recently established in France—the study of the history of medicine and the allied sciences considered from the multiple point of view of the evolution of doctrines and institutions, biography, bibliography, and documentary research. *Are we always to* remain behind our continental neighbours in this speciality? National vanity alone should negative the objection, for if such a society can thrive in France, why not in England? In the second place, the fact remains that the subject is very rarely discussed in any of the existing societies and the reason is not far to seek. The number of those who take a real and lasting interest therein is comparatively small. In the provinces they are generally only to be found far apart from each other, and there, as in London, a paper upon some topic allied to medical history read at one of the societies' meetings is by no means sure of gaining the approbation, if the attendance, of members. For it must be generally conceded that the present apathy of the bulk of medical men with reference to the history of their profession constitutes a gross anomaly. There is no professorial chair of the subject in any of our universities; it is included neither in the schedules of education nor examination—even as an optional subject—at any of our medical schools; and there is no existing society which makes it a speciality.

Having already taken the initial steps towards the formation of such a society, I venture to place the scheme before the profession and to ask for further support.

I am, Sirs, yours faithfully,

GEORGE C. PEACHEY.

Brightwalton, Wantage, Feb. 17th, 1902.

## GREY HAIR AND EMOTIONAL STATES.

*To the Editors of* THE LANCET.

SIRS,—In his article on "Grey Hair and Emotional States," published in THE LANCET of March 1st, p. 583, Dr. Robert Jones refers to the connexion of grey hair with certain states of the nervous system. That such connexion exists there can be no doubt. We can, I think, speak more definitely and say that abnormal greyness is an infallible index of some defect in the nervous system—a defect which may range from comparative slight instability, manifesting itself as mere nervousness, to one so pronounced as to culminate in such grave disorders as angina pectoris and insanity. This statement is founded upon an examination of a large number of cases extending over several years, and it is because I am sure that it embodies a truth of considerable practical value to the physician that I am venturing to draw attention to it here.

But what, it will be asked, *is* abnormal greyness? We shall best answer this question by enumerating the characters of normal greyness. Between the normal and the abnormal there is, of course, no sharp dividing line—the one runs imperceptibly into the other—but, speaking generally, we may say that the chief features of normal greyness are: (1) it does not come on before, say, the age of 35 years; (2) it is symmetrical; (3) it begins in certain regions, preferentially the temples (so named on account of this very fact) spreading thence; (4) the blanching progresses gradually; (5) the blanching on the scalp does not proceed decidedly in advance of that on the face.

We are now in a position to give the features of abnormal greyness: (1) Premature blanching of the hair is the most important sign of it, and the earlier the greyness appears the greater the abnormality—thus it is greater in one who turns grey in his twenties than in one who does not begin to go grey till in his thirties; (2) asymmetrical greyness is so well recognised to be due to defective nervous action that I need not further insist upon the fact; (3) greyness which does not begin in symmetrical foci spreading thence, but affects the whole scalp or beard equally in all its parts, is, unless it progresses slowly, generally abnormal; (4) rapid blanching is always abnormal; and (5) when the whole of the hair on the scalp is decidedly grey, while that on the face retains its colour completely, the condition is abnormal We may frequently observe this condition in men in their early thirties or early forties. I have never observed the exact converse of this, though it is quite common for men to grow more rapidly grey in the beard than in the scalp; this I do not regard as abnormal.

These, Sirs, are, in my opinion, the marks of abnormal greyness, and when any one of them is pronouncedly present we may infer the existence of nervous instability.

I am, Sirs, yours faithfully,

Wimpole-street, W., March 2nd, 1902. HARRY CAMPBELL.

*To the Editors of* THE LANCET.

SIRS,—Dr Robert Jones has drawn attention to this subject in an interesting paper in THE LANCET of March 1st. There are cases of localised blanching of the hair which illustrate the influence of nervous changes. I do not now refer to the white hairs sometimes found in long-standing cases of neuralgia, but to cases of whitening of the eyelashes and eyebrows in connexion with sympathetic ophthalmia and spontaneous irido-choroiditis. A number of these cases have now been recorded.[1] I saw one case of this kind in a girl, aged 15 years, who, when first seen, had been blind for four years from severe inflammation of the eyes unconnected with injury. The history was clear that the eyelashes and in part the eyebrows had become

---

28·6 per 1000 during the week ending March 1st. During the past four weeks the death-rate has averaged 27·9 per 1000, the rates during the same period being 26·5 in London and 22·3 in Edinburgh. The 208 deaths of persons belonging to Dublin during the week under notice showed a decline of 34 from the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against 11 in each of the two preceding weeks; of these, five resulted from whooping-cough, three from "fever," three from diarrhœa, one from measles, and one from scarlet fever. These 13 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rates during the same period being 2·9 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been two, three, and two in the three preceding weeks, rose again last week to five; the deaths referred to "fever," which had been two, two, and three in the three preceding weeks, were again three last week, and the fatal cases of diarrhœa, which had been two in each of the two preceding weeks, increased last week to three. The 208 deaths in Dublin last week included 35 of children under one year of age and 66 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the respective numbers recorded in the preceding week. Two inquest cases and five deaths from violence were registered; and 65, or nearly one-third, of the deaths occurred in public institutions. The causes of 12, or nearly 6 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE

Staff Surgeon William George Kynaston Barnes has been promoted to the rank of Fleet Surgeon in His Majesty's Fleet. Dated Feb. 27th, 1902.

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in His Majesty's Fleet:—Frederick William Parker, Philip Nicholas Randall, George Goss Borrett, Walter Henry Skinner Stalkartt, George Alexander Stuart Bell, and John Ambrose Keogh. Dated Feb. 21st, 1902.

Staff Surgeon H. Meikle has been appointed for service at R.N. Rendezvous, Spring-gardens.

### IMPERIAL YEOMANRY (IN SOUTH AFRICA).

The Imperial Yeomanry Depôt: Captain E. T. Vint, Medical Officer, is granted the temporary rank of Major, Dated Jan. 1st, 1902.

### ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel George Arthur Hughes, D.S.O., is granted the local rank of Colonel whilst acting as Principal Medical Officer at Hong-Kong. Dated Oct. 12th, 1900.

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major W. S. Cheyne to be Surgeon-Lieutenant-Colonel. Dated March 5th, 1902. Surgeon-Lieutenant J. P. Brown to be Surgeon-Captain. Dated March 5th, 1902.

### IMPERIAL YEOMANRY.

North Somerset: The undermentioned officer resigns his commission:—Surgeon-Lieutenant J. G. D. Kerr. Dated March 5th, 1902.

### VOLUNTEER CORPS

*Rifle:* 1st Volunteer Battalion the Northumberland Fusiliers: James Graham Miller to be Surgeon-Lieutenant. 4th Volunteer Battalion the King's (Liverpool Regiment): Lieutenant Edward Lucas Hughes resigns his commission and is appointed Surgeon-Lieutenant. 3rd Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment): Surgeon-Lieutenant R. G. Hann to be Surgeon-Captain. 2nd Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Surgeon-Lieutenant F. N. Cookson resigns his commission; Edward Churchill Stock to be Surgeon-Lieutenant. 2nd Tower Hamlets: Surgeon-Lieutenant E. T. McDonnell to be Surgeon-Captain.

### VOLUNTEER INFANTRY BRIGADE.

*Staffordshire: Surgeon-Captain* C. A. *MacMunn*, 3rd Volunteer Battalion the South Staffordshire Regiment, to be Brigade-Surgeon-Lieutenant-Colonel on appointment as Senior Medical Officer to the Brigade.

### SOUTH AFRICAN WAR NOTES.

Surgeon-Captain George Davidson Laing, attached to the 5th Battalion the Imperial Yeomanry, was slightly wounded in the right leg during the action with Colonel Von Donop's column.

The following officers have been discharged from hospital to duty:—Major G. T. H. Thomas, R.A.M.C., Major C. J. Holmes, R.A.M.C., Captain W. T. Mould, R.A.M.C., and Civil Surgeons Ilott, Bell, Jensen, Brown, and Fleming.

Major C. W. R. Healey, R.A.M.C., and Lieutenant L. E. L. Parker, R.A.M.C., are on passage home.

## Correspondence.

"Audi alteram partem."

## FORSYTHE *v.* LAW.

*To the Editors of* THE LANCET.

SIRS,—*In the recent trial Forsythe v.* Law certain allegations were made against me, which, if true, would rightly expose me to disapproval, especially among my professional brethren. May I, therefore, point out certain things which were *stated, or insinuated,* and which *were quite without* foundation and absolutely untrue.

1. The plaintiff was in a dying condition when she came under my care. There was and could be no doubt that huge doses of morphia and especially chloral had been taken by or administered to her at that time. This was admitted by Dr. W. T. Law. It was also admitted that she had very grave heart disease and these *drugs* had produced a very serious condition of health. She had had an extra large dose of chloral just before I saw her, and on arrival at 62, Ladbroke-grove, this began to take effect to an alarming extent and she required very great care. This was successfully treated and then began the effects of withdrawal of the opium. I was quite prepared for emergencies, they did arise as I had anticipated and were successfully combated. *The one great danger was, however,* due to the condition of her heart, rendered more dangerous by the exhibition of chloral. I was supported in my treatment by Dr. George *H.* Savage, the eminent specialist, who, I think, is in a better position than any other man to know whether or not I was correct. He did not alter one single detail, but quite agreed that I was doing right in treating the case as I was. The allegation that *I was not* treating the case scientifically and successfully therefore falls to the ground. Dr. Law's own witnesses showed that.

2. It is asserted that *force was used to remove her* and that she was under restraint in what the judge, without a shred of justification, termed a madhouse. *No force was used whatever.* She came freely and without any undue persuasion. She was not under restraint, except that she was continuously watched and tended by a nurse. She was free to go out of the home if she wished to do so. The so-called madhouse was an ordinary medical and surgical nursing home. Dr. Law admits, and I agree, that she had certain suicidal tendencies due to the chloral; these we watched and they quickly passed off. She expressed gratitude to me for stopping the morphia on many occasions.

3. Mr. Bankes, K.C., asked the judge to note the word "we" in my answer, "We did not think it wise to let her be put into the witness-box." *He* was quite aware that "we" meant that another doctor and I had examined her and considered it unsafe for her to appear. I need not give that doctor's name; he may not wish it, but the certificate signed by him was put in. Mr. Bankes wished it to appear to the judge and jury as if I were a party to the trial; that I deny absolutely and he was not justified in making that allegation. At the very first I told Dr. Law to try to avoid the scandal *and exposure* which a trial would mean to him. I did so entirely in his interests. It was no business or interest of mine whether the trial came off or not, but I all along hoped it would not come off. I had nothing to do with it except in so far as I was called *upon to exam*ine and make notes on prescriptions submitted to me for that purpose. I was bound on oath to find fault with these. They were almost all without directions of any kind—a most dangerous and unprofessional way of

Of course, the Midwives Bill makes no provision for nursing. It never did. All it does is to "protect title" after registration and so it is on all fours with the Medical Acts. It is clear that Parliament will *never* protect medical, surgical, or midwifery practice so that in the end quackery (that is, unlicensed practice) will destroy the medical profession. It is not a pleasant prospect for those seeking to enter the ranks of legitimate medicine, and, with the exception of those entering the public services and of the holders of certain appointments, the rank and file have a poor look-out. Unqualified practice is rampant throughout the country, and I am at present taking charge of a practice in a northern county where two unqualified men in the relationship of principal and assistant do the leading practice. It is not an exceptional case, and I can imagine the disgust of the new midwife when she finds herself in keen competition with the ignorant and dirty Gamp. Indeed, her only hope of salvation is in becoming a drudge to the men who still cultivate cheap midwifery.

I am, Sirs, yours faithfully,

Liverpool, March 3rd, 1902. ALEXANDER McCOOK WEIR.

## THE DECAY OF AUSCULTATION AND THE USE OF THE BINAURAL STETHOSCOPE.

*To the Editors of* THE LANCET.

SIRS,—Dr. Charles W. Chapman's remarks in THE LANCET of March 1st, p. 618, on "The Decay of Auscultation and the Use of the Binaural Stethoscope" lead me to suggest another perhaps not very generally-recognised advantage peculiar to the binaural variety. I have found that if, while percussing the chest, the stethoscope be left hanging in the ears, with the chest-piece dangling close over the part struck, the notes produced are considerably, and in many cases very helpfully, amplified. The true path of the sound is not readily recognised by the ears, and it is only when one stops up the stethoscope end that one is forced to the right conclusion.

I am, Sirs, yours faithfully,

Cheltenham, March 3rd, 1902. EDGAR G. TREVITHICK.

## THE DISSEMINATION OF KNOWLEDGE CONCERNING VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—The suggestion of Dr. Herbert W. G. Macleod in THE LANCET of March 1st, p. 618, on "The Dissemination of Knowledge concerning Vaccination," is an excellent one, but he appears to be unaware of the fact that something is already being done in this matter. I may, however, remark that it is not very easy to obtain audiences for lectures on such a subject as vaccination, even at a time when it is so prominently before the public as it is at present, except in one of two ways—either by putting up a lecturer to decry vaccination, as the Anti-vaccination League so frequently does, when those who arrange the lecture will also take some trouble to collect an audience, or by giving pro-vaccination lectures through the agency of organisations which are in touch with the class of people one wants especially to reach. Such agencies are mothers' meetings and the systematic lectures on health given by the lady teachers under the various county councils. Ever since its foundation the Jenner Society has been in increasing relations with both sets of these agencies and has given them all the assistance in its power in the way of suggestions, literature, diagrams, &c., and I doubt whether there is any more effective way of carrying on this form of educational work. I may add that the society has a series of lantern slides which it lends out for such gatherings and which have been found very useful. If Dr. Macleod were to see the large correspondence on this subject alone with which the Jenner Society has to deal he would find that the ground is not so unoccupied as he appears to think. Still, there is plenty of room for more effort, and I have done my best to invite the coöperation in it of medical officers of health, as Dr. Macleod suggests, who, when a favourable opportunity occurs for doing so, are in a position to give valuable help in this matter.

There is another direction of a cognate kind in which the Jenner Society has found considerable scope for activity, and that is in connexion with the numerous public lectures, debates, and discussions on the vaccination question which have during the last five or six years, and just no more than ever, been taking place in all parts of the country. My experience in the correspondence with which I have ha to deal in this matter has shown me that the supporters of vaccination are generally at much disadvantage when compared with their anti-vaccinationist opponents from a want of appreciation of what I may call the controversial perspective of their subject. The anti-vaccinationist attack has been organised by men who are keen enough to see what are the most effective points that they can make, and even where those who undertake the attack have no real knowledge of their subject they can repeat the "patter" which is provided for them in a way which puts their less adroit antagonist often at considerable disadvantage; in fact, it is the story o our experience in South Africa over again in another form. Boer "slimness" is more than a match for British "frontal attacks" until the Britisher learns from the tactics of his opponents that in this as in other matters *fas est ab hoste doceri.* To facilitate this desirable result the Jenner Society has provided a series of notes for lecturers and debaters on the subject of vaccination which I have reason to think have been found useful.

I am, Sirs, yours faithfully,

March 4th, 1902. FRANCIS T. BOND, M.D. Lond.,
Honorary Secretary, Jenner Society.

## ROYAL COLLEGE OF SURGEONS IN IRELAND.

*To the Editors of* THE LANCET.

SIRS,—I send you a few statistics concerning the passes and rejections of the Final Fellowship examinations of the above College as they may be instructive to those of your readers who have followed my correspondence in your journal under the heading of "A Dangerous Principle."

| Year. | Pass. | Reject. | Total candidates. |
|---|---|---|---|
| 1897... ... ... ... ... ... | 5 | 7 | 12 |
| 1898... ... ... ... ... ... | 18 | 5 | 23 |
| 1899... ... ... ... ... ... | 10 | 4 | 14 |
| 1900... ... ... ... ... ... | 35 | 0 | 35 |
| 1901 (up to February) ... | 18 | 1 | 19 * |

* One examination.

I can hardly expect that the President, Vice-President, and Council of the College will so far relax the reticence they have hitherto observed towards the letters of mine which appeared in THE LANCET, but should they do so an explanation as to whether the "Charter" witnesses were present at any Fellowship examination in 1900 would be of much interest.

It seems hardly possible to believe that of 35 candidates for Fellowship in a given year the average answering should be so rich in success as was the case in 1900, unless, indeed, there were some explanation which the ordinary practitioner had overlooked.

I am, Sirs, yours faithfully,

Dublin, Feb. 24th, 1902. S. WESLEY WILSON.

## ACUTE SUFFOCATIVE PULMONARY ŒDEMA.

*To the Editors of* THE LANCET.

SIRS,—I am obliged to Dr. Auld for his reference to Laennec. In preparing my lecture on "Acute Suffocative Pulmonary Œdema"[1] I did not, unfortunately, think of consulting the writings of the famous French physician, although I might easily have done so, as both the original and the translation are on my book-shelves. However, had I come across the paragraph quoted by Dr. Auld it would not have interested me in this connexion, as I cannot see that it has any except the most general bearing upon the affection with which I was dealing. The quotation in Dr. Auld's letter, with the exception of the italics in the last sentence of it and two words "when" and "but" in the middle of it, is to be found in Forbes's Translation, fourth edition, 1834, p. 81.

---

[1] THE LANCET, Jan. 11th, 1902, p. 73.

white after the eye trouble had set in. These cases are certainly rare and it has been stated that the whiteness of the eyelashes is a mere coincidence. This I do not believe and I think that the neurotic origin of the blanching in these cases is supported by evidence derived from comparative pathology. Mr Beddard in his book on "Animal Coloration" writes (pp 19-20): "There is certainly evidence that coloration has some relation to the distribution of the underlying nerves. Mr Allen has stated that the white marks on the head of the tiger correspond to the area of distribution of the infra-orbital nerves. The nerves terminate in or near the skin, and it is clear that there must be some connexion between nerve-supply and coloration from the fact that in a hedgehog whose spines were white the nerves in connexion with the muscles for contraction of the skin were greatly diseased. There are plenty of other pathological facts of a like nature."

Another question follows—What nerves are implicated when blanching of the hair occurs? Do they belong to the sympathetic or to the cerebro-spinal system? In favour of the former we have Pouchet's experiments quoted by Professor Semper in his book "Animal Life," p. 96 "These experiments proved that the changes already observed by Lord Lister (then Mr Lister), and alluded to by Dr Jones, were brought about through the agencies of the optic and the sympathetic nerves I fully agree with Dr. Jones that "the influence of nervous changes upon the hair has not been fully worked out"

I am, Sirs, yours faithfully,
E DONALDSON.

Londonderry, March 3rd 1902

---

## THE UNIVERSITY OF DURHAM AND THE MEDICAL CURRICULUM.

*To the Editors of* THE LANCET.

SIRS,—In your account of the proceedings of the recent special session of the General Medical Council you quote from the Confidential Report of the Special Committee on the Curriculum (February, 1902). I beg to inform you that Paragraph VI of the Recommendations of the Committee, viz. "That the University of Durham, by recognising all the courses of study which are recognised by all the licensing bodies in Schedule A of the Medical Act, 1858, accepts many courses of study in the subjects of physics, chemistry, and biology which have been recognised by the Conjoint Board of England, but have not been approved by the Medical Council," &c., was drawn up on imperfect information, and that for the last five years the University of Durham has only accepted instruction in chemistry, physics, and biology received at the following institutions—(*a*) The recognised medical schools in Great Britain and Ireland; (*b*) the Durham College of Science, Newcastle-upon-Tyne, and the other university colleges in the kingdom. The report of the committee was therefore amended, before being presented to and adopted by the Council, by Paragraph VI of the Recommendations of the Committee being completely withdrawn and the University of Durham placed on the list of the examining bodies which conformed to the General Medical Council's requirements

I am, Sirs, yours faithfully,
GEORGE HARE PHILIPSON,
Representative of the University of Durham on the General Medical Council.

March 3rd, 1902

⁂ Sir George Philipson will see that although we published the Recommendations of the Special Committee as they were originally drawn up we also stated that the reference to the University of Durham was deleted.—ED L

---

## "WHAT'S WHAT?"

*To the Editors of* THE LANCET.

SIRS,—I regret to trouble you again concerning "What's What" and the references to London medical men in its Appendix, but your article on "Publicity for Medical Men in the Lay Press" in THE LANCET of March 1st, p. 604, and the correspondence which you publish between Sir Anderson Critchett and myself at p 618 in the same number leave me no alternative.

First, I beg to inform you that the letter which I wrote to Sir Anderson Critchett was intended to be private, that I gave him no authority to publish it, and that I consider his doing so (without any permission from or notice to myself) to be simply unjustifiable.

Next, Sirs, I beg to inform you that whatever paragraphs may or may not be withdrawn from the future editions of "What's What" you are mistaken in saying that I have already withdrawn those which have been lately in question. What alteration I may make in the future remains to be seen. At present my action is purely confined to the expression of regret that any words of mine should have caused personal annoyance to those members of the medical profession to whom they refer and a specific promise to certain gentlemen that I will omit their names from any future edition. I do not in the least admit or consider that I have written anything to which exception could reasonably be taken or that there is a single word in the paragraphs in question for which any apology is necessary. The whole point of the matter lies in the fact that advertisement is so common nowadays that professional men are morbidly sensitive to even the breath of a suspicion that they can be guilty thereof, and that, as I have realised, from the letters written to me by them, the extent of this morbid sensitiveness, I have thought it courteous and desirable to inform them that I am sorry that it should have been aroused by my action.

To return, Sirs, to your article I hope that you will allow me to deny, in the strongest manner, that I desired "to do some persons a good turn by lauding them at large." I desired nothing of the kind I had not the remotest idea of doing these persons—these surgeons and doctors—a good turn by lauding them Not one of them is a personal friend, several of them I have never seen, and my only connexion with them has been that which I stated, when I said that I had had actual experience (either in my own person or in those of relations and intimate friends) of their capacity and skill.

I should have wished, Sirs, to answer the subsequent arguments in your article, which deal with the main point at issue—the only one with which the public has any real concern, but to do so would be to occupy your space to a greater extent than you would probably desire or permit; and I will therefore publish my reply in another medium. I think that there will be no difficulty in showing that the balance of advantage to the public lies in publicity and not in secrecy, that the only persons who have anything to fear from the former are the incompetent and fraudulent; and that both the medical man and his clients have everything to gain by being brought into direct communication with one another At present you will observe that, by your own admission, the medical and *quasi*-medical men who are recommended to the public are the less desirable members of the profession, a fact which in itself goes far to prove the desirability of some alteration.

With apologies for the length of this letter, the last with which I propose to trouble you,

I am, Sirs, yours faithfully,
HARRY QUILTER.

Manchester-square, W., March 4th, 1902

⁂ We do not see how Sir Anderson Critchett could guess that Mr Quilter meant his letter to be private, nor can we understand why Mr. Quilter should resent its publication, especially in view of the publication by other medical men of his correspondence with them.—ED. L.

---

## THE MIDWIVES BILL.

*To the Editors of* THE LANCET.

SIRS,—Referring to your leading article on "The Midwive Bill" in THE LANCET of March 1st, p. 606, there wa only one way to avoid the errors which you deplo and that was by introducing a "nursing Bill" at the commencement of the session, and I need not remind your readers that the whole of the candidates for Direct Representation on the General Medical Council last autumn pledged themselves to do so, and I need hardly say that they have failed to do so The material for such a Bill was in their hands and Parliament must have given it their attention, but there being nothing before the House but the Registration Bill it was naturally taken for granted that the Bill in question had the general approval of the profession Nor need the General Medical Council complain. The Council was warned both before and at the date of the election that "the Privy Council would make short work of their recommendations," and so it has happened, and in the new Midwives Board the Council will have a powerful rival. That is why I did my best to impress this fact on the candidates.

Of course, the Midwives Bill makes no provision for nursing. It never did. All it does is to "protect title" after registration and so it is on all fours with the Medical Acts. It is clear that Parliament will *never* protect medical, surgical, or midwifery practice so that in the end quackery (that is, unlicensed practice) will destroy the medical profession. It is not a pleasant prospect for those seeking to enter the ranks of legitimate medicine, and, with the exception of those entering the public services and of the holders of certain appointments, the rank and file have a poor look-out. Unqualified practice is rampant throughout the country, and I am at present taking charge of a practice in a northern county where two unqualified men in the relationship of principal and assistant do the leading practice. It is not an exceptional case, and I can imagine the disgust of the new midwife when she finds herself in keen competition with the ignorant and dirty Gamp Indeed, her only hope of salvation is in becoming a drudge to the men who still cultivate cheap midwifery

I am, Sirs, yours faithfully,
Liverpool, March 3rd, 1902 ALEXANDER McCOOK WEIR.

have during the last five or six years, and just now more than ever, been taking place in all parts of the country. My experience in the correspondence with which I have had to deal in this matter has shown me that the supporters of vaccination are generally at much disadvantage when compared with their anti-vaccinationist opponents from a want of appreciation of what I may call the controversial perspective of their subject The anti-vaccinationist attack has been
organised by men who are keen enough to see what are th
most effective points that they can make, and even wh
those who undertake the attack have no real knowled
their subject they can repeat the "patter" which is p

the subject of vaccination which I

Now I am convinced that the affection described by Laennec in his paragraph on "acute suffocative catarrh of adults and children" is not the affection which I endeavoured to describe in my clinical lecture. It may be frankly admitted that all acute suffocative affections of the lungs, as Dr. Auld indicates at the end of his letter, present certain general resemblances to one another, but this by no means implies that they are the same either in degree or in kind. If Laennec's description be compared with that in my lecture important differences will be found which, to my mind at least, conclusively prove that the two accounts do not refer to the same affection.

Laennec is dealing with an acute suffocative catarrh "*affecting the whole, or a very large portion, of the mucous* membrane of the lungs", I am dealing with acute suffocative pulmonary œdema. The duration of the catarrh "is from 24 to 48 hours, or at most some days." The duration of the suffocative œdema in my cases was on an average about six hours. In suffocative catarrh, at the end of 24 or 48 hours, or at most some days, "either the patient dies, or expectoration commences and puts an end to the suffocation, and the disorder then follows the progress of a simple acute catarrh." In suffocative œdema "almost simultaneously with the onset of the dyspnœa—a most important diagnostic point—expectoration of a perfectly white, finely frothy, watery sputum begins." In acute suffocative catarrh "while the suffocation lasts there is little cough" (I use here the words in my copy of Forbes's translation, which are a little different from those in the quotation), "and the expectoration, if any, is altogether pituitous or fluid." In acute suffocative pulmonary œdema "the frothy fluid seems to flow up the trachea and is expelled with a 'hawk,' as if clearing the throat, but *there is* no cough in the ordinary sense of the word."

The affection described by Laennec is a matter of days; that described in my lecture is a matter of hours. In my first case there was no cough or spit either before or after the suffocative attack had passed off, which it did in about six hours; the suffocation and the profuse expectoration were cotemporaneous and both ceased together. These are differences as *to the essential nature of the two affections* which, to my mind, no degree of general resemblance can reconcile, and which convince me that I have not mistaken cases of acute suffocative catarrh for acute suffocative pulmonary œdema.

I am, Sirs, yours faithfully,
Glasgow, Feb 24th, 1902. JOHN LINDSAY STEVEN.

## THE PREVENTION OF WATER-BORNE DISEASES IN THE ARMY.

*To the Editors of* THE LANCET.

SIRS,—On reading your leading article on the above subject in THE LANCET of Nov 30th, 1901, p. 1507, I was reminded of the hugely beneficial effects of the cream separator in prolonging the keeping time of butter. This machine must separate not only cream and milk but also cream and germs. It seems permissible, therefore, to wonder whether some adaptation of the centrifugal principle might not prove efficient as regards water and germs. Such an apparatus would probably be less cumbersome and more rapid in its action than any yet proposed—given only its efficiency.

I am, Sirs, yours faithfully,
Hamilton, Victoria. R. W. HUGHSTON, M.B Melb.

## A METHOD BY WHICH DEPOSITION OF MOISTURE ON THE LARYNGEAL MIRROR MAY BE PREVENTED WITHOUT THE AID OF HEAT.

*To the Editors of* THE LANCET.

SIRS,—I have no knowledge of the "crayon anti-buée" to which Dr. Walker Downie referred in THE LANCET of March 1st, p 589, but the desirable result of preventing the deposition of moisture on a laryngeal mirror may readily be brought about by rubbing the mirror with a piece of damp soap. The smeared surface thus produced is polished by rubbing off the film of soap with a soft cloth. A mirror so prepared will not become clouded if breathed upon for some time (over an hour provided the tongue does not touch it)—a point of some value if a lengthy examination has to be made. The fewer instruments with which a practitioner has to be provided nowadays the better, and as soap is always at hand the simplicity of the process has much to recommend it. Why soap should have this effect I do not pretend to explain, nor do I know who was the first to apply it for the purpose mentioned.

I am, Sirs, yours faithfully,
March 4th, 1902. ETONENSIS.

## ISOLATION HOSPITALS AND WELL-TO-DO PATIENTS.

*To the Editors of* THE LANCET.

SIRS,—Will you please tell your readers accurately and fully what would happen if anyone in what are called the "upper classes" catches small-pox? I myself, through the accident of birth and industrious sires belong to the class who toil not, and I have no idea, nor has my medical attendant, whether in the event of my catching small-pox I shall be able to enjoy the illness at home, or whether I shall be hauled out of bed and carted by force to a Metropolitan Asylums Board small pox hospital. Nor if allowed to remain at home do I know who will be allowed to attend me or what precautions will be enforced to prevent the spread of the infection. No doubt I ought to know, but I find that nobody seems to know. If you are good enough to reply will you also tell us what would happen if the same state of things occurred *outside the limits of the Metropolitan Asylums* Board's area. No object in giving my name, so allow me to sign myself—

Yours faithfully,
March 2nd, 1902. SILVER-SPOON.

⁂ To a certain extent our correspondent's question has been answered in a leading article which appeared in THE LANCET of Feb. 1st, 1902, discussing isolation accommodation. A member of the upper classes catching small-pox will be well advised to do as the medical officer of health advises. A sensible medical officer of health would never insist upon the removal of a patient to an isolation hospital who could be effectively isolated in his own house and properly attended by his own medical man. Outside the jurisdiction of the Metropolitan Asylums Board the circumstances would be altered by the fact that there might be no isolation hospital. If there were one, the medical officer of health to the urban or rural authority would be the best person to advise whether an individual case should be nursed at home or not. We may add that our correspondent is too modest, for if his sires had not placed him on the top shelf he would soon have got there by himself.—ED L.

## AN INDIAN MEDICAL STUDENT'S GRIEVANCE.

*To the Editors of* THE LANCET.

SIRS,—I have for some time been seeing a notice put up on one of our university boards about the "West African Medical Staff" services. I did not pay much attention to that till I have seen THE LANCET of last week (Feb 8th). In that under the heading "The West African Medical Staff" I notice that among other qualifications a European parentage is necessary for the candidature for the services. This excludes those who are, though British subjects, yet fortunately or unfortunately not born of European parents; this therefore excludes Indian medical students as well. Now do I wish to draw the attention of the British public, specially of those class of peoples who are of unbiased mind—I mean the members of the medical profession—to the injustice thus done to the Indian medical students of this country. Why should those of us who have come up to this country, been educated in the distinguished universities, studied, worked, been examined and passed together alongside the white men, I am at a loss to understand, be refused a right which our fellow students will enjoy? Shall I understand, then, that this is a distinction of colour and nothing else? It is all very good to extend a hand to accept a help from India in time of need. We do not grumble at it, we do not refuse it, though famine and pestilence have become our daily visitors. Everyone knows how assistance in various shape from Indian princes and Indian contingents was utilised in the present South African.

war. It is also known how the Indian soldiers upheld the British prestige in distant China. Is this the way, then, the Colonial Office intends to repay the services of India? This is surely not the means by which the British public can expect to gain the confidence of the Indians.

I am, Sirs, yours faithfully,
AN INDIAN
Feb. 17th, 1902. (a Member, University Edin.).

# MAIDSTONE AFTER THE EPIDEMIC.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

*A Comparison between the Sanitary Work done before and after the Typhoid Fever Epidemic of 1897: the Necessity of Better Sanitation Vindicated, while the Contamination of the Water-supply remains Problematical.*

MAIDSTONE suffered from so severe an epidemic of typhoid fever in 1897 that all sanitary measures taken in this town have become matters of more than local interest. Everyone must be anxious to know what is being done to prevent the recurrence of so terrible an epidemic. Indeed, Maidstone now constitutes an object-lesson for all students of hygiene. It will be remembered that Maidstone was considered an exceptionally healthy town. For the 10 years preceding the epidemic the average annual death-rate was 14·54 per 1000 on a population of 33,830, while the mean death-rate for England and Wales was 18·57 per 1000. The epidemic commenced in September, 1897, and by Jan. 1st in the following year 1786 cases had been notified in the town, 107 in the County Asylum, and 45 in the Maidstone Rural District. The epidemic, however, was at its height from Sept. 11th to Oct. 16th, and the three worst weeks were those ending on Sept 25th, Oct. 2nd, and Oct. 9th, when the number of cases notified for each were 544, 529, and 246 respectively. The average zymotic death rate for Maidstone had been 1·68 per 1000, but in 1897 the death-rate from the seven principal zymotic diseases rose in consequence of the epidemic of typhoid fever to 5·52 per 1000. The general impression prevailed at the time that the epidemic was caused by the contamination of the Farleigh water-supply, though the Eberth bacillus was never found in that water. The districts affected corresponded, however, with the distribution of that particular water-supply; but in the special reports and map published in THE LANCET at the time it was shown also that the districts were on high levels ranging from 100 feet upwards. Exceptionally and in one part of the town only the Farleigh water was distributed to houses built on levels as low as 40 feet; but here, strange to say, the epidemic did not follow the water-supply, though it prevailed near at hand, but in the houses that were on a higher level. This suggested that there were other causes than the water-supply and among these was the fact that the branch sewers went up to the higher levels and might act as ventilating shafts for the main collectors that were at the lowest level. These main collectors were not self-cleansing, a considerable number of the branch sewers were very badly built, while the domestic drainage was in a deplorable condition. Many of the closets had no flushing apparatus and were not properly connected with the street sewers. The subsoil was often polluted by broken and leaking drains. Further, though Maidstone is so small a town it had its slums and its poor living in badly ventilated, dirty, and overcrowded houses All these sanitary defects required as much attention as did the question of water-supply, though the tendency was to hold the water as being solely responsible for the disaster that had befallen the town. Indeed, I was politely informed at the time that my arguments, though ingenious, were quite at variance with the [illegible] of modern science and that the idea of considering hoid fever as a sewer fever was out of date. Still I sisted in comparing bad sanitation to the powder and a taminated water-supply to the spark that produced the plosion, and I urged that it was quite as important to study disposing causes as to investigate the more immediate son of the outbreak.

It is now satisfactory to note that these arguments, though rgetically repudiated, have nevertheless produced good cts. Theorists are welcome to continue to argue that the [illegible] and the water alone was to blame if at the same time they tacitly admit the contrary by energetically striving to improve the public sewers and the private drains. Moreover, I also urged that by so doing they would prevent other epidemics besides those due to typhoid fever, and this contention was confirmed by the fact that an epidemic of diphtheria followed closely upon that of typhoid fever. But the excessive prevalence of diphtheria has now ceased, and this at the very time that improved methods of ventilating the sewers were introduced. So that, in spite of the bacillus which we were told must have been in the water though it was never found there, something can still be said in favour of good drainage, as an effective means of preventing epidemic disease. Let us, therefore, now see what has been done in Maidstone in this respect since the great epidemic.

First and foremost there stood the financial difficulty, aggravated by the fact that the epidemic has cost the town council £17,496, notwithstanding the Mansion House Relief Fund which had raised the sum of £27,918. Nevertheless, and even before the sanitary inspectors could examine premises and serve notices, a great number of private householders took alarm, had their drains overhauled, and in many instances found it necessary to relay them, to add ventilating pipes, and to improve the closets. Many thousands of pounds were thus spent of which there can be no public record. The authorities, however, wisely determined not to trust to this laudable display of private enterprise, but they immediately after the epidemic was over commenced a systematic inspection of every house in the town. The drains in each case were tested if possible by the water test. Then four street sewer ventilating shafts, 35 feet high, were placed in connexion with the sewers in 1897, before the epidemic had quite ceased.

To show the wholesome effect which the epidemic has had in stimulating sanitary work I will take some of the more important items one by one. Thus, during 1896, the year before the epidemic, drains were reconstructed, or were provided where they did not exist, to 200 houses. In 1897 the authorities appear to have been too occupied with the epidemic to do very much work of this description, for the number of houses so treated amounted to only 156. On the other hand, the epidemic was no sooner over than great activity in this respect is recorded, for new drains were provided to 476 houses in 1898, to 416 houses in 1899, and to 303 houses in 1900. The number of drains repaired and cleaned was 436 in the year before the epidemic, 340 during the year of the epidemic, and no less than 2050 in the year after the epidemic. In 1899 drains were repaired and cleaned in 681 houses and in 1900 in 574 houses. The water-closets that were repaired and cleansed in 1896 numbered 300 and in 1897, 250, but for the three years following the epidemic these figures rose to 798, 572, and 525. 40 new water-closets were constructed in 1896 and 20 in 1897. Then for the three years following the epidemic these figures were increased to 84, 84, and 105 respectively. One of the grievances especially complained of was that a great many water-closets were not provided with water, but could only be flushed by hand, the inhabitants having to pour water from pails or jugs down their closets. In 1896 flushing apparatus was affixed to 346 water-closets, and this was done in 284 cases during the year of the epidemic. Here, again, we have a notable illustration of the practical effect produced by the typhoid scare, for in the following year a flushing apparatus was provided to 911 closets, in 1899 to 823 closets, and finally in 1900 to 644 closets. Only three old drains were trapped and ventilated from the sewer in 1896 and six in 1897. But in 1898 this was done in 31 instances, though only in one case during 1899 and in 26 cases in 1900. The gullies in the yards were also in a very defective condition and in 1893 trapped stoneware gullies were substituted for old and defective brick or bell traps in 233 cases This was done in 180 cases in 1897. Then, after the epidemic, this grievance is also taken actively in hand and in 1898 no less than 620 stoneware gullies are provided. The next year 629 more are laid and 389 in 1900. All these items may be grouped under the heading of "Domestic hygiene." Coming now to the point where the sanitation of the private dwelling merges into that of the street or public sewer, the new glazed drainage pipes laid in 1896 amounted in all to 4625 feet in length and to precisely the same length in 1897. But the difference for the year following upon the epidemic is very characteristic, for the total length of new hardware drain pipes laid amounted to 18,427 feet. Nor is this all. Where the drain-pipes run under houses and especial risks are incurred cast-iron pipes are now used, and 1387 feet of this sort o

Now I am convinced that the affection described by Laennec in his paragraph on "acute suffocative catarrh of adults and children" is not the affection which I endeavoured to describe in my clinical lecture. It may be frankly admitted that all acute suffocative affections of the lungs, as Dr. Auld indicates at the end of his letter, present certain general resemblances to one another, but this by no means implies that they are the same either in degree or in kind. If Laennec's description be compared with that in my lecture important differences will be found which, to my mind at least, conclusively prove that the two accounts do not refer to the same affection

Laennec is dealing with an acute suffocative catarrh "affecting the whole, or a very large portion, of the mucous membrane of the lungs"; I am dealing with acute suffocative pulmonary œdema. The duration of the catarrh "is from 24 to 48 hours, or at most some days." The duration of the suffocative œdema in my cases was on an average about six hours. In suffocative catarrh, at the end of 24 or 48 hours, or at most some days, "either the patient dies, or expectoration commences and puts an end to the suffocation, and the disorder then follows the progress of a simple acute catarrh." In suffocative œdema "almost simultaneously with the onset of the dyspnœa—a most important diagnostic point—expectoration of a perfectly white, finely frothy, watery sputum begins." In acute suffocative catarrh "while the suffocation lasts there is little cough" (I use here the words in my copy of Forbes's translation, which are a little different from those in the quotation), "and the expectoration, if any, is altogether pituitous or fluid." In acute suffocative pulmonary œdema "the frothy fluid seems to flow up the trachea and is expelled with a 'hawk,' as if clearing the throat, but there is no cough in the ordinary sense of the word."

The affection described by Laennec is a matter of days; that described in my lecture is a matter of hours. In my first case there was no cough or spit either before or after the suffocative attack had passed off, which it did in about six hours; the suffocation and the profuse expectoration were cotemporaneous and both ceased together. These are differences as to the essential nature of the two affections which, to my mind, no degree of general resemblance can reconcile, and which convince me that I have not mistaken cases of acute suffocative catarrh for acute suffocative pulmonary œdema.

I am, Sirs, yours faithfully,
JOHN LINDSAY STEVEN.

SILVER-SPOON.

March 2nd, 1902

*** To a certain extent our correspondent's question has been answered in a leading article which appeared in THE LANCET of Feb. 1st, 1902, discussing isolation accommodation. A member of the upper classes catching small-pox will be well advised to do as the medical officer of health advises. A sensible medical officer of health would never insist upon the removal of a patient to an isolation hospital who could be effectively isolated in his own house and properly attended by his own medical man. Outside the jurisdiction of the Metropolitan Asylums Board the circumstances would be altered by the fact that there might be no isolation hospital. If there were one, the medical officer of health to the urban or rural authority would be the best person to advise whether an individual case should be nursed at home or not. We may add that our correspondent is too modest, for if his sires had not placed him on the top shelf he would soon have got there by himself.—ED. L

## AN INDIAN MEDICAL STUDENT'S GRIEVANCE.

*To the Editors of* THE LANCET.

SIRS,—I have for some time been seeing a notice put up on one of our university boards about the "West African Medical Staff" services. I did not pay much attention to that till I have seen THE LANCET of last week (Feb. 8th). In that under the heading "The West African Medical Staff" I notice that among other qualifications a European parentage is necessary for the candidature for the services. This excludes those who are, though British subjects, yet fortunately or unfortunately not born of European parents; this therefore excludes Indian medical students as well. Now do I wish to draw the attention of the British public, specially of those class of peoples who are of unbiased mind—I mean the members of the medical profession—to the injustice thus done to the Indian medical students of this country Why should those of us who have come up to this country, been educated in the distinguished universities, studied, worked, been examined and passed together alongside the white men, I am at a loss to understand, be refused a right which our fellow students will enjoy! Shall I understand, then, that this is a distinction of colour and nothing else! It is all very good to extend a hand to accept a help from India in time of need. We do not grumble at it, we do not refuse it, though famine and pestilence have become our daily visitors. Everyone knows how assistance in various shape from Indian princes and Indian contingents was utilised in the present South African

Provinces, 1182; the Punjab, 4102; Mysore State, 587; Hyderabad State, 195; and Kashmir, 371. The latest returns for Bombay city and for Calcutta show that the outbreaks in these two cities are rapidly developing. The disease is still very virulent in Karachi, Poona, and Bangalore. The evidence with regard to inoculation is very conflicting. In the Punjab plague is raging where inoculation was extensively carried out last year, while, on the other hand, at Poona there were 6681 inoculations last year with the occurrence of only 11 cases and seven deaths amongst the inoculated. After all what are 7000 inoculations in a population of nearly 100,000? This week over 12,000 deaths have been recorded and yet only 10,706 doses of vaccine were sent out from Bombay. Inoculation is pushed in a few places, but is absolutely neglected in others.

The Victoria Memorial Scholarship Fund for training native women as midwives has been a great success. Over six lakhs of rupees have been raised and the fund is now closed. It has been decided that each locality shall profit by its own subscriptions, and the committee is re-allotting the interest from local contributions for the purpose of training midwives in the various districts. Already in Hyderabad a class has been started, and in Mysore, Rajputana, Gwalior, Travancore, Hulwa, Gondal, and Chamba young *dais* (nurses) have come forward to be trained in the female hospitals of those States.

The committee of the Indian Famine Relief Fund recently met in Calcutta and resolved to close the fund and to make over the balance (some six and a half lakhs of rupees) to the Indian Peoples' Fund.

The final census report for Assam shows the population to be 6,126,343—an increase since the last census of 11·8 per cent. One or two districts, however, were enumerated for the first time. Of the above population 725,844 persons are described as foreigners—that is to say, they were born out of Assam. This shows, at any rate, that the immigration is considerable

A great controversy has recently been raging in Calcutta concerning the Christian cemetery. More ground is urgently required and the health officer and others have advocated a fresh cemetery in the suburbs. Considerable opposition, however, has been made to this, chiefly by the Church parties, who desire an extension of the existing grounds. Apart from sentiment there can hardly be two opinions upon the undesirability of cemeteries in the heart of a city. It is unfortunate, also, that in a city like Calcutta a properly-constructed crematorium has not been provided The Hindus burn their dead as soon as possible after death, generally within a few hours, and the exigencies of the climate compel Mahomedans and Christians to bury their dead very speedily. There is a growing feeling amongst the Christian community that cremation is the preferable method for disposal of the dead. As these matters come under the administration of the municipality I consider the erection of a crematorium to be one of the reforms which ought to be undertaken without further delay.

Feb. 8th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

*The Stanley Hospital.*

THE committee's report for 1901 showed that 1105 persons had been treated as in-patients, with a total number of attendances of 57,218, or a daily average of 156. As many as 387 persons were brought to the hospital by the ambulance. Throughout the whole year the resources of the charity had been taxed to the utmost. All the available beds had been continuously occupied, and the staff had more than ever felt how limited the accommodation for in-patients was and how great was the necessity for opening the whole hospital; but the committee, under the pressure of the present large debt, had felt quite unable to face the extra annual expenditure that would be incurred by opening the closed wing. The new out-patient department had been found to work very satisfactorily, notwithstanding the fact that the out-patient and casualty work had been exceedingly heavy. Owing to the dearth of young medical men caused by so many having gone to the seat of war in South Africa the committee found it impossible to obtain at former salaries suitable candidates for vacancies on the resident staff. It was consequently placed in a position of difficulty, from which it was extricated by the generosity of Mr. C. J. Williamson, who promised to give £30 a year for five years to augment the salaries of the house surgeons. The expenditure for the year amounted to £5381, and the income, apart from the ex-Lord Mayor's hospital century fund (£948 12*s.*), was £3663, a decrease of £400 on the year 1900. Although an increase of £228 had been received from the Hospital Sunday and Saturday Fund and an increase of £77 in annual subscriptions, there was a falling-off of £610 in donations. In the matter of legacies the hospital had been again unfortunate, for out of all the handsome amounts distributed from this source it had received absolutely nothing during the past year, and only £50 in 1900. It seemed as if there were many who do not recognise the fact that the Stanley Hospital is one of the general hospitals of Liverpool and that it ministered to the necessities of a large and poor district otherwise unsupplied with gratuitous medical and surgical assistance. Starting the year with a debit balance of £4268, the ordinary expenditure had exceeded the ordinary income by £1736, against which £948 12*s.* had been received from the "Century Fund," leaving a debit balance of £5039. The committee urgently appeals to the charitably disposed for immediate help.

*The Small-pox Epidemic: Vigilant Precautions in Liverpool.*

The number of small-pox patients under treatment in the city hospitals remains at 44, no fresh cases being reported. A number of people, however, have been isolated for special observation In order to be on the safe side the medical officer of health has, since the commencement of the outbreak, exercised the utmost vigilance to prevent a spread of the disease, and it may be taken as a fact that only about 25 per cent. of the persons isolated actually develop small-pox; but the precautions are so exact that a person who betrays the slightest suspicious symptoms is isolated for a period. Stations have been opened in some parts of the city for the performance of free public revaccinations, and it is a gratifying fact to record that the "conscientious objector" is a comparatively *rara avis* in this city.

*The Bootle Borough Hospital.*

The fifty-ninth annual report of this hospital for 1901 states that a slight outbreak of fever in the early months of the year interfered to some extent with the work of the in-patient department and necessitated the partial closing of the wards for cleaning and re-painting. The opportunity thus offered was taken advantage of to repaint the entire building, to instal the electric light, to re-furnish the operating theatre, and to effect necessary alterations and improvements in the nurses' and servants' dormitories. The laundry plant had been renewed during the year. The accounts showed that after all the expenditure had been met the hospital debit balance was only £147. The committee recorded with deep regret the death of Mr. R. J. Sprakeling who for more than 30 years had been associated with the medical staff.

March 4th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

*Cardiff Infirmary.*

IN spite of the exceptional efforts made by the ex-Mayor of Cardiff during his year of office and of others to place the finances of the Cardiff Infirmary upon a sound footing the managers have not yet succeeded in securing a sufficient income to meet the annual expenses The expenditure during 1901 was £1815 more than the income received. There is no doubt that if the Cardiff working-men would only support the infirmary to the same extent that similar institutions are supported by their comrades in other large towns, such as Newport or Bristol, there would be ample means at the disposal of the managing committee. There were treated during last year 1663 in-patients and 14,282 out-patients by the staff of the infirmary.

*Small-pox Hospitals.*

A great deal of activity is being displayed in the provision of small-pox hospitals. The Mayor of Tenby has contributed £100 towards the cost of a temporary hospital for the borough, and the Portishead Golf Club has offered to the Portishead Urban District Council the pavilion of the club for use as an isolation hospital. The Whitchurch (Salop) piping were also laid in the course of the year Nor did the work stop here In 1899 almost equal activity was shown, as 17 410 feet of new glazed pipe drainage and 500 feet of cast iron pipes were laid Finally, in 1900 the new glazed pipe drains laid measured 13 793 feet and the cast iron pipes 523 feet If the seven items mentioned above and qualified as domestic hygiene are grouped together they amount for the two years 1896 and 1897 in all to 2794 sanitary improvements effected If, on the other hand, the same items are taken for the two years following upon the typhoid fever epidemic it will be found that 7776 similar improvements have been carried out Nor is this all, for though the figures for the third year show some falling off, they still remain very much higher than those that preceded the epidemic Then again when dealing with the connexion of houses with sewers and the sewers themselves it will be seen that in the years 1896 and 1897 there were in all 9250 feet of new glazed pipes laid, while during the following two years new pipes to the length of 37,714 feet were employed and this includes 1887 feet of cast iron pipes which constitute an extra precaution not generally applied before the epidemic These figures speak well for the activity of the Maidstone sanitary authorities and show that they have taken the lesson of the epidemic to heart But if the epidemic was caused exclusively by the contamination of the water supply, why take all this trouble to improve the domestic and public drainage? House-owners and public authorities are not prone to incur a large expenditure just on the off chance that it may be of some little use It is evident that in spite of all that was said to the contrary the warning given in these columns that the contamination of the water supply was probably not the only cause of the epidemic has been more generally heeded than was publicly admitted

During the year that followed the typhoid fever epidemic there were but 35 cases of this disease notified resulting in two deaths On the other hand, there were 240 cases of diphtheria This exceeded the highest previous record which amounted to the 211 cases that had occurred the previous year thus adding the stress of a minor epidemic of diphtheria to the terrible distress caused by the 1786 cases of typhoid fever Nevertheless the death rate for the year 1898 only amounted to 12 82 per 1000 which, however if compensation is allowed for age and sex constituted a mean death rate for Maidstone of 14 3 per 1000 and this latter figure may be compared with the mean death rate of 17 6 recorded for England and Wales during the same year The mortality from diphtheria at Maidstone was not high It was equal to 12 9 per cent of the cases

Before the typhoid fever epidemic the authorities had objected to the expense of frequent analyses of the water supply Their attitude was very different after the epidemic The Cossington supply was analysed 52 times that of the Boarley 53 times the Ewell 17 times and the Mid Kent 52 times during the year 1898 The Farleigh supply was absolutely suppressed and the Ewell water was only delivered for a time in the Barming district. Mixed waters were analysed on 21 occasions and of 13 samples from private wells 12 bore evidence of organic pollution Thus it will be seen that there is no longer any stinting so as to save expense in water analyses Mr M A Adams, who was then medical officer of health and public analyst reported that speaking generally, the quality of the public waters had been good In regard to the supplies from the chalk that of Boarley was excellent and that of Cossington was not so good The Ewell is a steady good, green sand water, but apt to contain too many nitrates and phosphoric acid The Mid Kent water also came from the greensand but was much softer and sometimes it did not contain a trace of nitrogen or ammonia. There was however a difficulty in getting a sufficient quantity as the season had been exceptionally dry During the same year the sanitary authorities reported as to the condition of unhealthy areas It was found that the average annual death rate during the previous 10 years among the inhabitants of Upper B nny s Yard amounted to 25 2 per 1000 This was nearly double that of the town taken as a whole and therefore forcibly suggested faulty local conditions. 39 out of 52 inhabitants never reached the age of manhood The deaths from diseases of the respiratory organs were in the proportion of 38 5 per cent of the total of deaths The houses in this yard are back to back and are very damp and squalid

During the year 1899 the epidemic of diphtheria continued and there were 213 cases resulting in 27 deaths There were also 21 cases of typhoid fever and the average death rate was 15 5 per 1000 of the total population Nevertheless the average death rate from the seven principal zymotic diseases only amounted to 1 16 per 1000 though the annual average for the previous 20 years was equal to 1 783 per 1000 Further reports were given by the medical officer of health on the housing question Eight houses in Kingman's Yard were described as being in a wretched state with damp, dangerous walls and staircases and windows that were too small Two closets were improperly placed and two others were full to overflowing There were 33 persons living here near to stagnant filthy accumulations of house refuse, with defective pavement in the yards and one out of three gullies blocked This property was described in the report as being unfit for human habitation In Dunn's Yard there were 10 houses with no water supply to the closets and with insufficient space and ventilation The cubic space of the rooms in Thomas's Yard averaged 650 feet The walls were crumbling away and the cubic space per inhabitant varied from 77 6 cubic feet 99 4 and 103 3 to 458 8 and 544 4 Had the rooms been properly apportioned there might have been 300 cubic feet per bed in three out of the six houses measured The windows were only two feet six inches square and there was no through ventilation in four of the houses In Temple Court there were 15 houses many of them back to back and all unsuited for human habitation

In November, 1899 Mr Adams retired and Dr Charles Pye Oliver succeeded him as medical officer of health Dr Oliver in his report for the year 1900 states that though the average annual death rate for East Maidstone equalled 16 8 per 1000 during the previous 10 years it rose to 18 1 for the year 1900 Taking both East and West Maidstone the death rate for the entire town was 15 81 per 1000 as compared with 18 3 per 1000 for the United Kingdom There were 28 cases of typhoid fever during the year and 150 cases of diphtheria The death rate from the seven principal zymotic diseases fell to 0 77 per 1000 During the course of the year some improvements were effected in regard to the insanitary condition of some of the poor quarters mentioned above and the overcrowding was abated But it must be confessed that so far as the housing problem is concerned no bold effort has been made to grapple with the difficulty A little tinkering may be noticed here and there It is the better class property that has been vastly improved by house to house inspection, followed by the reconstruction or repairs of the domestic drainage in every part of the town

*(To be continued )*

## NOTES FROM INDIA

(FROM OUR SPECIAL CORRESPONDENT )

*Plague Officers and the Indian Medical Service —The Plague Epidemic —The Victoria Memorial Scholarship Fund for Training Native Midwives —The Famine Relief Fund —The Census for Assam —The Cemetery Question in Calcutta*

THE following medical officers who have rendered good service in connexion with plague have been selected for admission to the Indian Medical Service Commissions have been offered to Dr Walsh Dr Horton, Dr Lewis, Dr Gloster and Dr Justice and nominations for commissions have been made to Dr Beach Dr Hunt, Dr Hayden, Dr Muat Dr Smith Dr Hills Dr Starkey Dr Sanderlands Dr Knapp-Barrow Dr Jameson and Dr Murray They will all be graded immediately below the batch of Indian Medical Service officers who next arrive from Netley These officers have been recommended by the respective Governments under which they have served and they were of the requisite age when they commenced their plague duties It will be only fair if appointments are offered to other plague officers who have done well but who are not otherwise eligible for the Indian Medical Service

Again a further increase is reported in the mortality from plague Throughout India there were 12,192 deaths last week as against 11 445 for the previous seven days and only 3415 for the corresponding week of last year Bombay city, the Punjab the North West Province and Bengal show great increase the published figures being —Bombay city, 408 deaths the Presidency 3822 Karachi 44, Madras Presidency 574 Calcutta, 82, Bengal 822, North West and on fittings in the library department and for an annual sum of £1500 for general and special library purposes. 3. They also agree to make application to the trust for a grant of £2500 in the coming year to be expended on equipment. The additions under this head are more immediately required in the laboratories and museums in natural physiology, chemistry, botany, zoology, geology, anatomy, physiology, pathology, and in clinical medicine and surgery and their special branches. 4. The court also regards it as important that provision should be made for the institution of research and other scholarships, chiefly in the faculties of science and medicine, and accordingly resolves to recommend to the Carnegie Trust that a sum of £1000 should be placed at the disposal of the court for that purpose for the forthcoming year. This sum would fall to be gradually increased in future years, but it may be expected that the requirements under this and paragraph 3, constituting together provision for the encouragement of scientific research and now stated at £3500, will not be materially altered. 5. It also agrees to submit an application to the trust for an annual grant of £4000 towards the maintenance and extension of the teaching and research work of the laboratories in the departments of physics, chemistry, botany, zoology, geology, anatomy, physiology, materia medica, pathology, public health, surgery, midwifery, tropical diseases, agriculture, and engineering, and towards the payment of the salaries of the demonstrators and assistants whose services will be required to meet the contemplated extension in the work of teaching and research. 6 The court is further of opinion that the following existing lectureships should be erected into professorships—viz., the lectureships in (1) French, (2) German, (3) applied mathematics, (4) ophthalmology, and (5) mental diseases. The court suggests that the trustees might annually set aside sums to be applied for the eventual endowment of new chairs. 7. The court is very desirous of instituting certain new lectureships in science, medicine, and commercial education, each of them for the tenure of five years, indicated in the relative ordinance of the Universities Commissioners; and it ventures, as in the case of the suggested new chairs (paragraph 7) to ask the trustees for information as to the manner in which they are prepared to aid in the establishment of such new lectureships. The above claims advanced by the court therefore involve the capital sum of £45,000 under paragraphs 1, 2, and 3, and permanent annual grants to the extent of £9000 under paragraphs 2, 3, 4, and 5 With [illegible]d to paragraphs 6 and 7 the court awaits the decision of [illegible]xecutive committee as to the amounts which it may [illegible]ble to advance towards these objects. The court would [illegible]k that if the capital sums above specified are granted [illegible]e executive committee the court will be prepared on the [illegible]ry of their period of payment to submit to the committee [illegible]oposals for grants for a further extension of the buildings [illegible] the University and for other academic purposes. The [illegible]urt then makes a statement with regard to the number [illegible] students for whom instruction has to be provided and the amount at present voted by the court from the University chest towards that purpose. The average annual number of matriculated students for the last five years has been 2812 The average number of students annually during the same period in the faculties of science and medicine has been 1550 The matriculated students for the present year are 111 more than during the corresponding period of last year. The grants provided by the University for the financial year 1900–1901 were as follows:—

| | |
|---|---|
| Stipends of lecturers ... ... ... .. ... ... ... ... | £3061 |
| Stipends of assistants ... ... ... ... ... ... ... ... | 6866 |
| Laboratories and class expenses .. ... .. .. .. ... | 2806 |
| Museums ... ... ... ... ... ... .. ... ... ... ... | 409 |
| Library... ... ... ... ... ... ... .. ... ... ... ... | 2662 |
| | £15,795 |

The University has practically no surplus income from which additions to those grants can be made for the purpose of extending the teaching in the existing departments or for the introduction of new subjects of study. The court regards the section of the trust under which application is made as intended to confer an enormous benefit on the universities of Scotland by providing means for their continuous development and it expresses the hope that the executive committee will be able to contribute to the University of Edinburgh a share of the income proportional to the numbers of the students and teachers and to the requirements of the subjects of study.

### *Aberdeen University.*

The senatus of this University met at King's College on March 1st and decided that the graduation ceremony should take place on Thursday, April 10th. In connexion with the subject of honorary degrees the senatus resolved to offer the degree of LL.D. to Sir Thomas Barlow, Bart., M.D., F.R.C.P., B.Sc. Lond., K.C.V.O., physician to the King's Household.

### *The late Mr. R. J. Cheves, M.B., Ch.B. Aberd.*

Much regret has been expressed in Aberdeen and district at the death of Dr. Cheves of Longside, who contracted pleurisy whilst visiting his patients and succumbed after confinement to the house for a few days. He was 25 years of age.

March 4th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Small-pox in Dublin.*

AT the monthly meeting of the Corporation of Dublin on March 3rd a report was received from the Public Health Committee giving a detailed account of the recent outbreak of small-pox and of the precautions taken to prevent the spread of the disease. The report added that the three patients were convalescent and that in the belief of the committee all danger of a spread of the disease had passed. A deputation attended from the City Hospital for Diseases of the Skin in support of an application made by that body for a grant of £150 a year from the corporation funds. The matter was referred to the Finance Committee.

### *Health of Belfast.*

At the monthly meeting of the Belfast City Council held on March 3rd it was reported that between Jan. 19th and Feb. 15th there had been notified 180 cases of zymotic disease—viz., 52 cases of typhoid fever, 44 of simple continued fever, 35 of erysipelas, 17 of diphtheria, 15 of membranous croup, 14 of scarlet fever, two of puerperal fever, and one of typhus fever. In the four weeks ended Feb. 15th there were 790 births registered in Belfast and 573 deaths, making a natural increase of 217. There were 41 deaths from zymotic disease, 86 from phthisis, and 183 from other diseases of the respiratory organs, making a total of 269 from the two latter causes. The annual death-rate from all causes was 20·8. On the whole the state of health of the city of Belfast continues fairly good and it is gratifying to be able to report that notwithstanding the prevalence of small-pox in London, Glasgow, and Liverpool, no case of this disease has so far been notified in Belfast.

### *County Down Infirmary.*

From the report of this institution from Jan. 1st to Dec. 31st, 1901, I find that the total expenditure for the year was £1619 1*s.* There were 462 patients admitted, which with those remaining from the previous year, 38, made 500 in all. The average number of beds occupied daily was 35, and the average cost of each patient was 2*s.* 5⅝*d.* per diem. The number of extern cases was 513. After the payment of all accounts a balance to credit of £247 5*s.* 4*d.* remained.

### *The Irish Poor-law Medical Service.*

The Council of the Irish Medical Association has brought under the notice of the senates and councils of the universities, medical colleges, and schools, the present condition of the Irish Poor-law medical service, in the hope that those intrusted with the provision of medical education may be induced to exert their influence to improve and reform this important public service in the interests of many of their present and future graduates and diplomates of medicine and surgery. The association begs the authorities of the Royal Colleges of Physicians and Surgeons and the Universities of Ireland to use their united influence to deter young professional men from entering this service until a minimum rate of remuneration has been fixed upon for Poor-law medical appointments, the salary in each case to be proportionate to the area of the district, and a reasonable one considering the onerous duties of the office. The average salary paid to dispensary medical officers represents a small fraction under £100 per annum, out of which he must pay all expenses necessary to the

District Council has decided, upon the recommendation of the medical officer of health, Mr. M. Gepp, to erect tents for the purpose of isolating any cases of small-pox which may occur in the district.

### *Dog Muzzling.*

The Board of Agriculture has issued an order requiring the muzzling of dogs in the boroughs of Cardigan and Carmarthen and in portions of the counties of Cardigan and Carmarthen and in the whole of the county of Pembroke.

### *Royal West of England Sanatorium.*

The annual report of the Royal West of England Sanatorium at Weston-super-Mare states that 1144 men and 981 women were admitted to the institution during 1901, that 990 of the total number were discharged recovered, and that 672 left in much improved health. The expenditure for the year amounted to £3506 and the receipts to £80 less than this sum.

### *Beri-beri or Arsenical Poisoning?*

At the last meeting of the West of England and South Wales Branch of the Incorporated Society of Medical Officers of Health Dr. Edward Walford, medical officer of health of Cardiff, read notes upon four cases of beri-beri which had recently occurred among European sailors who had arrived at the port of Cardiff. They left Rangoon on Sept. 12th, 1901, and 10 weeks later the first man was attacked, the three others falling ill in another three weeks, and upon arriving at Cardiff four weeks afterwards all four men were found to have typical symptoms of beri-beri. They were removed as soon as possible to the Seamen's Hospital and they all recovered. Specimens of hair were examined at the Cardiff Public Health Laboratory by Mr. Sugden, the assistant chemist and bacteriologist, and traces of arsenic were found in the hair taken from each patient. Acting upon the presumption that the disease was due to a micro-organism which after lying dormant had regained vitality in the heated atmosphere of the forecastle Dr. Walford considered that the patients suffering from the disease should be at once removed from the poisonous apartment which they were inhabiting, and that there should be a complete disinfection of all surfaces and articles which might retain infection, and he quoted Dr. Patrick Manson's opinion that "when patients are removed from endemic spots they at once begin to improve and may be out of danger in a few days, whilst those who remain in the endemic area most probably go from bad to worse and very likely die."

### *Health Reports.*

In his annual report for the Stroud Rural District the medical officer of health, Dr. J. M Martin, states that the birth-rate during 1901 was 20 6 per 1000 and the death-rate 13 per 1000. The population of the district was 27,770 Among the 666 rural districts in England and Wales only 17 have a larger population. It is satisfactory to find that regulations under the Dairies, Cowsheds, and Milkshops Order and By-laws with respect to nuisances and new buildings, which have been under consideration by the district council for two years, are now only awaiting confirmation by the Local Government Board.—The death-rate in the borough of Aberavon in Glamorganshire, which has a population of 7553 persons, was 15 5 per 1000 in 1901.—The birth-rate in the Yeovil Rural District, where there is a population of 17,537 persons, was 23·3 per 1000 during 1901 and the death-rate was 14 3 per 1000.—Mr. A. R. Nicholls, the medical officer of health of the Langport Rural District, in his annual report, states that many of the occupied cottages in his district are barely fit for habitation, the ground floors being in some instances of trodden earth. The birth-rate in 1901 was 25 5 per 1000 and the death-rate was 19·1 per 1000.

### *Treatment of Imbeciles.*

At a conference of the Somerset Poor-law and Rural District Councils' Association held at Taunton on Feb. 25th a discussion took place with reference to the separate accommodation of imbeciles and idiots. No definite resolution was come to upon the subject but the opinion of the conference appeared to be that such persons should not be treated in a lunatic asylum. It was suggested that they might be gathered from several unions into one institution which would not have to be built up to the requirements of the Commissioners in Lunacy, and the Langport Workhouse, which has accommodation for 300 inmates but is now only occupied by 50, was spoken of as one which might be adapted for such a purpose.

### *Hospital Sunday in Bristol.*

It has been decided to distribute £1400 among the Bristol hospitals from the Lord Mayor's Hospital Sunday Fund. The collections amounted this year to nearly £1600.

### *The New Workhouse Dietary.*

The average weekly cost per head of the inmates in the workhouse of the Wells Union for the half year ending Dec. 31st, 1901, was 2*s.* 9¾*d.*, and for the corresponding period of 1900, before the new dietary scale was adopted, the average cost was 2*s.* 10½*d.* The workhouse accommodates 300 inmates.

### *Proposed Repeal of the Conscientious Objector Clause.*

The Malvern Urban District Council has passed a resolution in favour of the repeal of Section 2 of the Vaccination Act, 1898, and has issued a circular letter to other district councils urging the adoption of a similar resolution. When this letter was discussed by the Chipping Sodbury Rural District Council the medical officer of health (Dr. Francis T. Bond) strongly urged the council not to acquiesce in the suggestion of the Malvern council, for he was of opinion that the section (which relates to the conscientious objector) was a very wise one in the interests of vaccination and had done practically no harm but a very distinct amount of good, for it had removed the possibility of a certain limited section of the community posing as martyrs. He declared that the actual number of exemptions under the section did not come to more than 5 per cent. of the children born in the country and they were obtained mostly in large centres where the agitation against vaccination had been most active.

### *Plymouth Borough Asylum.*

At Plymouth, on Feb. 26th, Colonel W. L. Coke, the Local Government Board inspector, held an inquiry into the application of the Plymouth Corporation for power to borrow £40,000 for the extension of the borough asylum at Blackadon. It was stated that an enlargement of the institution was urgently required, for although the asylum was erected to provide accommodation for 200 patients as a matter of fact there were 280 patients at present. The proposed extension will enable the authorities to provide accommodation for 406 patients.

March 3rd.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *University of Edinburgh and the Carnegie Trust.*

THE University Court of the University of Edinburgh has now laid before the Carnegie Trust a statement regarding the more urgent needs of the University. This document commences by explaining that in order to assist the court in preparing the statement the senatus had been requested to offer suggestions as to the direction in which University extension was most required. The various faculties had accordingly considered their wants and had reported to the senatus which, in its turn, had sent in a report on the whole subject to the court. A representation on the subject had also been received from the General Council of the University. The statement then gives an account of the various legacies and donations which had been received by the University during recent years. These in the aggregate amount to £91,000, this sum not including numerous endowments destined to the founding of bursaries, scholarships, and fellowships. Notwithstanding all that has been done recently the University is still in need of large additions to its buildings, to its teaching staff, and for educational appliances. The more urgent needs of the University are then given and may be stated briefly as follows: 1. The court concurs in the opinion that the most urgent need of the University is a building for natural philosophy and engineering and agrees to ask the Carnegie trustees to set aside £8000 annually for five years as a contribution towards the fund which the court proposes to raise for the purpose of purchasing ground for the future extension of the University buildings and in the first instance for the erection thereon of class-rooms and laboratories for the teaching of natural philosophy and engineering. 2. The court and senatus agree as to the importance of increasing the efficiency of the University library and resolve to apply to the Carnegie Trust for a grant of £500 a year for five years to be expended on structural alterations who had died under chloroform. In not even one was there any valvular lesion found. Three patients had hearts thickly overlaid with fat but without any muscular degeneration, while in only one case was there any definite fatty degeneration found. These results gave a certain amount of support to the contention of M. Huchard. Of 19 patients who died under chloroform 14 died before the operation had begun, four died during the operation, and one died after it was over. The elder Doyen had pointed out how often renal mischief was found in cases of death under chloroform. M. Brouardel, however did not consider that renal mischief was a contra-indication to the use of chloroform. Deaths of patients under chloroform could only be compared from a medico-legal point of view with those occurring from very slight shocks, especially to the laryngeal region, which had been known to cause death. Emotion, even that produced by touching the part about to be operated on, or the first incision, had caused death. Such deaths, therefore, ought not to be attributed to chloroform, even though the patient were under that drug at the time.

March 4th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *The late Professor Julius Wolff.*

DR. JULIUS WOLFF, professor of orthopædic surgery in the University of Berlin, died on Feb. 18th after a short illness, the cause of death being apoplexy. He was born in 1836 in Märkisch-Friedland, West Prussia, and after completing the medical curriculum at Berlin University he took his degree in 1860 and in the following year became qualified to practise. He commenced professional life as a general practitioner in Berlin, devoting his leisure time to researches in anatomy and physiology. The histology of bone had a special interest for him, and in common with the late Professor von Meyer of Zürich he investigated the connexion between the trabeculæ and the growth of bone. Osteology was, in fact, the favourite study of his life, on which account in Berlin medical circles he was familiarly known as "Knochen-Wolff" (i.e., "Bones"). His intimate knowledge of osteology and the experience of military surgery which he gained in the wars of 1864 and 1866 led to his giving up general practice in order to devote himself to surgery, and he succeeded so well in this new field that although he had never been assistant to a surgical teacher he was nevertheless as early as 1868 appointed *privat-docent*, and in 1884 extraordinary professor of surgery, in Berlin University. Orthopædic surgery and plastic operations of various kinds, particularly those for hare-lip, were his specialty. On the founding of a chair of orthopædic surgery in 1890 Professor Wolff was appointed to it, and the Royal Orthopædic Clinic was formed by uniting his private clinic with the one belonging to the university. In 1892 his great work on "The Transformation of Bones" was published under the auspices, and at the expense, of the Royal Academy of Berlin.[1] Physically, Professor Wolff was a tall, strong-looking man; he was universally liked by his professional brethren and his death is much regretted.

### *A Boycotted Hospital.*

As a general rule the hospitals of Berlin and its environs are in a state of chronic overcrowding, but there is a notable exception in the case of the hospital at Lichterfelde. This nstitution has beds for 350 patients, but it seldom happens hat more than 200 of them are occupied, the explanation of his dearth of patients being that the hospital is boycotted oth by the medical men of the district and by the local ithorities on account of the peculiar methods of treatment d management which are in operation there. The chief edical officer of this hospital is Professor Schweninger, who ame a celebrity with the public as the medical attendant the late Prince Bismarck. Even in illness the prince was from being a tractable subject, but Dr. Schweninger's tural energy of character was equal to the occasion, d by the exercise of a kind of suggestion he succeeded in lieving the nervous troubles from which his patient ffered. The Iron Chancellor's gratitude took the form of rocuring for him an appointment as professor in Berlin niversity, despite the unanimous opposition of the edical faculty. The news that an important professorhip had been disposed of in such a way caused general astonishment and the incident gave rise to very ani debates in Parliament. Dr. Schweninger had never anything for the advancement of medical knowledge, the peculiar views which he held caused him to be rega by his medical brethren as being in some degree an outs He used to say, for instance, that modern medicine w failure; that students were nowadays trained in the scie of medicine whereas what the public required were trained in the art of medicine—men who knew how to c their patients. Exact diagnosis, he maintained, was necessary for the purpose of treatment; a medical man oug to be as much at home in the kitchen as in the laborator and he intended to found a new medical school, an Aerzt Schule where his principles would be taught to the student The Lichterfelde hospital, of which he was made chi physician, gave him an opportunity of treating hospita patients according to the system which he had hithert followed in his private practice, but the anticipated result were not realised; on the contrary, this new and lavishly fitted-up hospital has from the first been a source of trouble to the council of the district of Teltow to which it belongs. At an early period there was a general strike on the part of the nurses—perhaps a unique event in the history of hospitals; then Professor Schleich, the chief surgeon, resigned because Professor Schweninger wished to decide in every case whether a surgical operation was necessary or not, thereby placing the surgeon in the position of a mere operator. No other surgeon accepted the vacant post, the result being that fractures of the femur were treated by massage and that plaster bandages were applied to strangulated hernia, whilst cancer was never operated on at all, being, in Professor Schweninger's opinion, a constitutional disease. The most striking fact, however, was the enormous death-rate from diphtheria. In the other Berlin hospitals, where the serum treatment was used, the diphtheria mortality was from 12 to 13 per cent., but in the Lichterfelde hospital it was 64·7 per cent. This state of affairs soon attracted the attention of the medical profession and the authorities of the district. Dr. Rabnow, president of the medical association of Schöneberg, a town in the Teltow district, published a statement to the effect that the medical practitioners of that place declined to send patients to the Lichterfelde hospital; the municipal council of the town also declined to pay the annual sum of 50,000 marks (£2500) which had been its contribution to the hospital, and other places in the district took a similar course, so that financial difficulties arose. At the last meeting of the Teltow district council the Landrath (governor of the district) took an optimistic view, saying that in his opinion the charges made against Professor Schweninger were due to the hostile feeling of the medical profession and that on an inquiry being held by the medical officer of health of the district it was found that the hospital was in a good condition and that the patients had expressed their satisfaction with their general treatment. The leading journals, however, both medical and non-medical, controvert his statements and express disapproval of the system followed at the Lichterfelde hospital.

### *German Medical Congresses.*

The Congress of the German Surgical Society will meet from April 2nd to the 5th in Berlin under the presidency of Professor Kocher. The principal subjects of discussion will be the Dressing of Wounds on the Battlefield, introduced by Professor von Bruns of Tübingen; the Histogenesis of Carcinoma, by Professor Gussenbauer; the Treatment of Carcinoma of the Bowel, by Professor von Mikulicz; Operations for Subphrenic Abscess, by Professor Körte; Colopexy, by Professor von Eiselsberg; and Orthopædic Surgery, by Professor König.—The Congress of Internal Medicine will meet at Wiesbaden from April 15th to the 18th, Professor Naunyn in the chair. The official subjects of discussion are Photo-therapeutics and the Diagnosis and Treatment of Gastric Ulcer.

March 3rd.

## CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

### *Imperial Medical Society of Constantinople.*

FEBRUARY 15TH was the anniversary of the foundation of the Imperial Medical Society of Constantinople, of which Djemil Pasha is the newly-elected president. Djemil Pasha is a very skilful surgeon; he is one of the professors discharge of his duties, and rent, taxes, horse, vehicle, servants, &c., so that practically no portion of his salary is available for his support, for which he has to depend on the small emoluments arising from registration and vaccination fees, averaging about £30 per year, together with whatever private practice the district may afford him. It is noted that in Bragan District, Monaghan Union, the medical officer is paid a yearly salary of £29 19*s.* 2*d.* for attending a district of 12,388 statute acres and with a population of 1964 persons, and his vaccination fees were for one year 8*s.* The medical officer of Portstewart District, Coleraine Union, has a salary of £43 0*s.* 1*d.* for a district with a population of 2761 and an area of 9116 acres, and for the year ended March 1st, 1900, his vaccination fees were 10*s.* There is no promotion in the service, no holidays as of right, no increment of salary no matter how long or efficient the medical officer's service may have been, no recoupment of official expenses however epidemics or other local conditions may increase them, and there is no pension, unless, indeed, the medical officer should be successful in begging as a favour that which he should have as a right. Under such circumstances is it strange that there are deep and lasting discontent and dissatisfaction in the ranks of the Poor-law medical service officers, and that they are determined to make an effort to have these truly anomalous conditions of the service rectified? It is recommended (1) that £200 per annum be fixed as the minimum salary for any dispensary appointment, and £120 per annum for any workhouse appointment, unless held jointly, when £300 should be the amount for both; (2) that all medical salaries should be subject to a quinquennial increment, either based on the civil service scale or at a fixed percentage rate; (3) that a yearly holiday of one month as a right should be fixed, with well-defined rules as regards the appointment and payment of a substitute; and (4) that there should be superannuation on civil service scale as a right. It is hoped that a united effort will at last be made to improve the Poor-law medical service of Ireland.

### *The New Public Health Law.*

THE new law on public health to which I referred in my letter in THE LANCET of March 1st, p. 624, was published in the official journal on Feb. 15th, 1902, and will henceforth be known in legislation by that date. As everybody knows the law has been under consideration for some 20 years, and its provisions have been altered over and over again, for the various committees which had it under consideration were exposed to a cross-fire from hygienists on the one side and politicians on the other, the latter of whom desired to avoid imposing on their constituents sundry expenses which would make them unpopular and which would place their re-election in great doubt. To-day, although the definite text of the law is published, it is easy to foresee the various difficulties which will arise in its vigorous application when the various centres of population refuse to carry out the regulations. With a view to economy the law creates no new official and the mayors of every commune are constituted as sanitary officers; but these mayors are elected by the people. It will be the mayor's duty to publish various sanitary rules and regulations which will deal with (1) sundry precautions to be taken against infectious diseases, and especially with measures for disinfection; and (2) various regulations dealing with the sanitary condition of houses, of furnished lodgings, and other dwelling-houses, whatever be their nature, and especially with the questions of the supply of drinking-water and the removal of dust and other refuse. If any mayor has not published his code of sanitary regulations within one year from the date of the publication of the law, the prefect shall publish one himself; and it is easy to see that, in the majority of cases, this is what will happen, for the majority of mayors in the little country communes have not the slightest idea of drawing up sanitary regulations. If the mayor issues his regulations and the prefect does not pass them the latter official can modify them after having given notice to the departmental hygienic council. This amounts to saying that the Government has tried to avoid the responsibility of measures which might make it unpopular among country populations and has striven to throw all the responsibility upon the mayors. Nevertheless, the mayor, in his quality as chief of the municipal police, will have to see that the regulations published are carried out, whether they come from himself or from the prefect. It is certain, however, that no mayor will have any authority to impose upon his constituents hygienic measures which will annoy them in any way, such as the destruction of insanitary premises, compulsory disinfection, or a rate for "*canalisation*" for a supply of drinkable water. The law has provided for the case of a mayor being obviously incapable, whether from ignorance or from ill-will; and within three years from a definite statement to this effect by the departmental hygienic council, the prefect will be able *ex officio* to draw up sanitary measures such as he considers will be useful—that is to say, he will be able to act on his own responsibility or else do nothing at all if the deputy representing the *arrondissement* should belong to the Government majority and should not wish to annoy his constituents. The prefect, however, cannot enforce these measures without having first referred the question to the Minister of the Interior who will, in his turn, submit it to the Consultative Hygienic Committee of France which will proceed to order a committee of inquiry. With the consent of these two committees the prefect will be able to put the commune under the obligation of carrying out the necessary works. If within three months these works are not carried out a decree of the President of the Republic in Council will authorise the prefect to have the works carried out at the expense of the commune; but, in order to compel the commune to enter the expenses for these works in the communal budget there must be another special decree passed on the matter by the Chamber of Deputies and by the Senate. It is easy to see that this complicated procedure will very rarely be put in action, especially in communes the deputies of which belong to the Government majority. The communes represented by members of the minority will thus be the only ones likely to see the sanitary regulations rigorously applied to themselves, according to the principle which, as a matter of fact, dominates the whole of French politics—viz., that the application of the law is simply a form of political oppression. It is obvious that where the law is strictly carried out there will be a violation of the rights of private property. One peculiarity of this new law is that it provides for *bureaux d'hygiène* to assist the mayors; but only in communes of 20,000 inhabitants and over, although communes of 2000 inhabitants which possess a bathing establishment are also provided with such *bureaux.* Sanitary measures relating to houses are not applicable except in communes of 20,000 inhabitants and over. This distinction is foolish, for there are many localities of less than 20,000 inhabitants where the population is wholly industrial in which the application of the rules as to the populations of the large towns would be equally indispensable. The regulations concerning vaccination or revaccination will probably be properly carried out, for public opinion has for some time been prepared for such a measure. "*Canalisation*" for drinking-water and for the construction of sewers will probably be more difficult to carry out properly. The Academy of Medicine within the next six months will publish a list of notifiable infectious diseases which every medical man will be bound to notify. This obligatory notification, which has already been laid down by the law of 1892, concerning the practice of medicine has not, up to the present, been strictly observed, and it certainly will be none the more so when medical men see that the result of their notification will be compulsory disinfection. Compulsory disinfection will be pretty easy in the large towns, but in the little towns and in the country where the departmental service is charged with the duty of seeing the law carried out it is probable that the measures will meet with violent resistance due to prejudices which will take a long time to overthrow. In this matter, as in so many points, the question of education comes in

### *Chloroform Anæsthesia in Patients Affected with Morbus Cordis.*

A discussion was commenced on Feb. 11th at the Academy of Medicine on the question of administering chloroform to patients with morbus cordis. M. Huchard, who opened the discussion, was of opinion that chloroform was the safest anæsthetic in cases of morbus cordis. Anæsthesia ought to be brought about gradually, but it should be profound before the operation began. The anæsthetist should be skilled and it was most important that he should give his whole attention to his duties. M. Berger supported M. Huchard. M. Brouardel, who spoke late in the discussion, related the results of 25 post-mortem examinations made on the bodies

### *Surgeon-General of the Navy.*

Captain Pressley M. Rixey, medical director of the United States navy, formerly attendant physician of the late President McKinley, has been nominated as Surgeon-General of the navy by President Roosevelt, in ratification of the promise of his lamented predecessor. This promotion gives Dr. Rixey the rank of rear-admiral; he succeeds Rear-Admiral William K. Van Reypen, who is placed on the retired list with the rank and retired pay of a senior rear-admiral. Dr. Van Reypen has been in the service over 40 years.

### *The Health of Havana.*

Major Gorgas, chief sanitary officer of Havana, reports on the health of Havana as follows. The entire health of the city for the year just ended over the preceding years is wonderful. There has been a very large decrease in the number of deaths in almost all of the different diseases. This is especially true of yellow fever; there have been few cases in comparison with the record last year and the last three months of the present year were absolutely free from the disease. The cause of the decrease in yellow fever is undoubtedly due to the work on the theory that the mosquito is the transmitter of the disease. During the month of December there has been no yellow fever or small-pox.

### *The Prosecution of a Health Officer for the Examination of Prostitutes.*

The compulsory examination of prostitutes by officials has always been extremely unpopular in the United States. It appears, however, that the health officer of Cincinnati, Ohio, has been enforcing examinations as a public health measure and the result has been a suit brought against him by a tax-payer. The petition of the plaintiff stated that the defendants "have adopted and are enforcing a regulation requiring all known prostitutes in said city to submit to a personal examination once every week by the district physicians to determine whether they are affected with any venereal disease, and if found free therefrom each prostitute receives a certificate containing her personal description and the recital of the fact that she is free from disease, which certificate can only be obtained from the health officer and must be conspicuously displayed in the room of such prostitute; that these certificates are made out in triplicate, one for exhibition by the person examined, one for the health department, and one for the chief of police; that if any prostitute is found to be affected with venereal or other infectious disease she is not permitted to remain an inmate of such house of prostitution or assignation, but is sent to the city hospital or branch hospital of the city; and, finally, that said district physicians charge each prostitute the sum of 50 cents for each examination and certificate." The plaintiff prayed for a restraining order on the ground that such examinations and charges for the same were an abuse of the corporate power of the city of Cincinnati. In reply, the defence stated that it was known to the health authorities that in certain houses and in specified localities contagious and infectious diseases prevailed more than in other parts of the city, and that the public health of the city required periodical visits and careful inspections of such places, as well as the examination of those suspected of disease; these measures tended to prevent and to restrict disease. The suit was dismissed.

Feb. 18th.

## Obituary.

### SAMUEL ALEXANDER KENNY STRAHAN, M.D. R.U.I.

THE receipt of the news that Dr. S. A. K. Strahan had died in London on Feb. 21st caused widespread regret in Belfast. After studying at Queen's College, Belfast, where he had a most brilliant career, Dr. Strahan graduated M.D. at the Royal University of Ireland in 1879. Coming afterwards to England he devoted his attention to the special study of mental diseases, and for many years he was the senior medical officer of Berrywood Asylum. While there he contributed largely to the *Journal of Mental Science*, the
subseq
ter. About th years ago, his health fa
he resigned his post at Berrywood and took a voyage
the world to try to improve the condition of his heart.
spring he went to Africa and visited some of the mil
hospitals where, unfortunately, he developed malarial
and was obliged to come home and to reside in Brigh
There his health improved and he was just about to arra
for a voyage to Australia when he became suddenly ill
died in London on Feb. 21st. Dr. Strahan was a man
great ability and gifts and was deservedly popular, and
unexpected death is very much regretted. He came o
clever family. One of his brothers, the late Professor of L
at Queen's College, Belfast, is Mr. James Strahan, LL.
who practises as a barrister in London; another brother is
leading solicitor in Belfast; and another brother, who was
medical practice in Belfast, was the late Dr. John Straha
who wrote several admirable medical works. Dr. S. A. K
Strahan was buried in Belfast on Feb. 26th.

### JOHN HENRY ECCLES, M.R.C.S. ENG., L.S.A.

WE regret to have to record the death of Mr. J. H. Ecc
of Plymouth at the ripe age of 87 years. After passi
through his curriculum at St. Bartholomew's Hospi
he qualified in the year 1839 and subsequently settl
in Plymouth. He there continued in active pursuit of h
profession for over 40 years. Always a man of thoroug
earnestness of purpose, it was not long before he receive
appointments of a public character, and at the time o
his decease he was consulting surgeon to the Plymouth Royal Eye Infirmary. He had also held numerous and important offices in connexion with the town and port, particularly that of medical inspector of emigrants. His cheery nature and great kindliness of heart made him a friend of many and won the esteem of all. He was an intense lover of nature and was never tired of showing to relatives and friends the natural beauties of his county and especially the magnificent view of the Sound from the historical Hoe. He was twice married and leaves a widow and many descendants to feel their loss. Three of his sons by his first wife followed in his footsteps as medical men, one of whom, Dr. Symons Eccles, predeceased him. Four of his grandsons are also members of the same profession.

### JOHN JAMES TWEED, F.R.C.S. ENG., L.S.A.

MR. TWEED, whose death occurred at his residence in Upper Brook-street, Grosvenor-square, London, W., on Feb. 22nd, was the son of a well-known surgeon who practised at Bishop Stortford, in Essex, where Mr. Tweed was born in 1819. Part of his school education was received at University College, London, and he afterwards prosecuted his medical and surgical studies at University College Hospital, of which latter institution he was a life governor. He became a Member of the Royal College of Surgeons of England in 1842, and was elected a Fellow in 1864, thus he was actively engaged in his profession for the unusually long period of 60 years. Mr. Tweed was the oldest inhabitant of Upper Brook-street and was one of the most hard-working and deservedly respected of the members of his profession. He was a Fellow of the Obstetrical Society of London and had had a very large obstetric practice, to which he devoted the best years of his life. He was remarkably abstemious and temperate in all things, never brilliant, but patient and enduring. His old-fashioned courtliness of manner and his attention to all those by whom he was consulted won for him the affection of a very large number of patients ar
friends.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—Th
deaths of the following eminent foreign medical men ar
announced:—Dr. Eugenio Fazio, *privat-docent* of Hygiene i
the University of Naples.—Dr. Chedevergne, Professor of Clinical Medicine at Poitiers.—Dr. Arthur Geissler, Director of the Statistical Department of the Kingdom of Saxony.—Professor Coshevnikoff, Director of the Moscow Clinic for Mental and Nervous Diseases.—Dr. Gustav Siegmund, one of the best known practitioners of Berlin, at the age of 81 year
In his earlier years he contributed numerous papers to the medical journals on medical chemistry and experimental pathology.—Dr. Alfonso Masi, lecturer on Operative Medicine in the University of Buenos Ayres.

surgery in the Constantinople Medical School and is also brother in law of the Sheikhislam, who holds the highest position in the religious system of Islam next after the Sultan This is the first time that Djemil Pasha has filled the presidential chair but he was elected one of the vice presidents of the society a few years ago, and it is hoped that he may succeed in convincing those in authority that it is in such financial straits that doubts are entertained as to the possibility of carrying it on much longer The society's position was explained to the Sultan by Dr Spirido Mavrogeny Pasha (an obituary notice of whom appeared in THE LANCET of Feb 8th 1902 p 411) and His Majesty several times asked the opinion of the society on various medical subjects, but the Government grant at present made to it is nevertheless only one fifth of that which it received from Sultan Mahmoud on its foundation in the time of the Crimean war An important paper on Epidemics of Dysentery in Tunis was submitted to the society last year by Dr Remlinger, in the course of which he stated that at the end of the disease there was very often a kind of general anasarca or œdematous swelling of different parts of the body unaccompanied by albumin in the urine This phenomenon has, however, been already observed in the chronic diarrhœa of children, and Dr Zavitzianos of Constantinople has mentioned these symptoms in articles which he has published on cholera infantum Another communication made to the society related to the destruction of rats on shipboard by means of carbonic acid but the author, a chemist in Constantinople unfortunately made his experiments, not with rats on shipboard, but with white mice in a cage on land The Austrian Lloyd Shipping Company, which naturally has an interest in the destruction of rats has informed the International Sanitary Board that on the first opportunity it will give facilities for making experiments under proper conditions—namely, in a ship which contains rats and also has cargo on board The International Sanitary Board has published a regulation requiring all vessels that enter the port of Constantinople to produce a certificate from the authorities of the port of departure declaring that there are no rats on board dead or alive In the absence of such a certificate vessels must go to Cavak at the entrance of the Bosphorus near the Black Sea where they must unload and have the rats exterminated by means of burning coal and sulphur Vessels in fact, go there now and then and, according to the official reports, the rats on board are all destroyed

### *Landing of Live Animals in Egypt Prohibited*

It has been announced from Alexandria that cattle or other animals sent from European Turkey will not be allowed to enter Egypt but will have to be slaughtered in the lazaretto It is well known that there is no prevalence of epizootic disease in European Turkey, and this step can only be explained as a protectionist device to favour Egyptian cattle breeding

### *Medical Education in Teheran*

It is reported from Teheran that the Shah of Persia has invited the medical members of the International Sanitary Board of Teheran to consider the question of improving the state of medical education in that capital, where it seems that there is a medical school of some kind either actual or nominal

Feb 24th

## NEW YORK

(FROM OUR OWN CORRESPONDENT )

### *Men in the Navy have no Right to Refuse an Operation if it is not Serious*

THE Navy Department by Acting Secretary Darling holds that an enlisted man in the Navy or Marine Corps has no right to refuse to submit to a surgical operation if it is not serious, but declines to lay down any rules for cases involving the loss of a limb or in which a man's life would be endangered He recommends the exercise of persuasion and diplomacy on the patient in serious cases but in minor cases he decides that the man who refuses to be operated upon may be court martialled and punished Incidentally, the department has overruled Rear-Admiral Louis Kempff, junior squadron commander on the Asiatic Station who refused to let surgeons operate on an unwilling patient. The decision of the department extend only to the enlisted men , no ruling has been made in the case of an officer, although a precedent was established by Rear Admiral Robley D Evans, who drew a revolver on the surgeons who came to cut off his legs after he had been severely wounded in the battle of Fort Fisher Admiral Evans retained his legs and remained in the service, though quite lame The case just decided was that of a marine private serving on the monitor *Monadnock* in Chinese waters The surgeon of that ship wanted to remove a foreign growth which unfitted the man for duty, but the marine refused He was reported to Admiral Kempff, who sustained his stand Then an appeal was taken by the Navy Department. The Bureau of Medicine and Surgery expressed the opinion that most cases of this character could be adjusted by using tact and persuasion in trying to induce the patient to submit to an operation, but held that where a minor operation was required the patient should be obliged to submit or be punished, and the Acting Secretary upholds these views

### *The Protection of Presidents*

A Bill for the protection of the President of the United States, the Vice President, and others, provides that any person who shall within the limits of the United States or any place subject to its jurisdiction wilfully kill or cause the death of the President or Vice President, or any officer in line of succession or who shall wilfully cause the death of any sovereign or chief magistrate of any foreign country, shall be punished with death An attempt to commit either of the offences mentioned is also punishable by death The Bill also provides a punishment of 20 years' imprisonment for the person or persons found guilty of instigating advising, or counselling the killing of any of the persons named , and any person who shall wilfully and knowingly aid in the escape of any person guilty of the offences mentioned shall be deemed an accomplice and punished the same as if a principal Imprisonment of five years is provided for persons convicted of uttering words, spoken or published, which threaten to kill or to advise or to instigate anyone to kill the persons named The Secretary of War is authorised and directed to select a detail from the regular army to guard and protect the person of the President, ' without unnecessary display and to make special rules and regulations as to dress arms and equipment of such guard, and to publish only such of the rules and regulations as he may deem proper

### *New Management for Bellevue and Allied Hospitals*

Bellevue and the allied hospitals, Harlem, Gouverneur, and Fordham and the Emergency Hospital, on Feb 1st passed from the control of the charities department to that of the recently appointed board of trustees, under the provisions of the revised charter This same system of trustee management is now in force in private hospitals in this and other cities and also in the city hospitals of Boston and Cincinnati The private hospitals of New York have always been thus managed but it is only in Boston and Cincinnati that the city hospitals have had the benefit of the plan In both these cities the city hospital was incorporated by Act of Legislature between 35 and 40 years ago, to be maintained as an institution by itself, independently of all other institutions charitable or otherwise In both cases the hospitals are models of their kind and will bear comparison with the best private hospitals in any of our cities In Boston the trustees are appointed by the Mayor, subject to the approval of the City Council In Cincinnati one member is appointed by the Governor two by the Superior Court of Hamilton County, and two by the Court of Common Pleas of Hamilton County In both cases these appointments are made without regard to political considerations In other large cities, such as Philadelphia Chicago St Louis, and San Francisco on the other hand, the public or city hospitals are a part of the department of public charities, and their control and management change as in New York with each change of the city administration In each case the hospitals being a part of a city department are considered to belong to the party in control and form an important share in the distribution of party patronage

### *Congressional Legislation on Typhoid Fever Notification.*

The House Committee has reported favourably on the Typhoid Fever Bill which reads as follows —

Every physician attending or called in to visit or to examine any case of typhoid fever in the district of Columbia shall at once send to the health officer of the district a certificate in ink signed by him stating the name of the disease and the name age sex and colour of the person suffering therefrom and setting forth the street and number, or other means sufficiently designating the house room or other place in which the person can be found, together with [illegible]

THE offices of the London and Counties Medical Protection Society, Limited, have been removed from 12, New-court, Lincoln's Inn, to more commodious premises at 31, Craven-street, Charing-cross, W.C.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. C J. Denny, M.R C S. Eng, L R.C.P Irel, on retiring from practice in Blackwater, has been presented (by his own request informally) with a cheque for £121 10*s.* subscribed by many patients and friends.

"THE CONSCIENTIOUS OBJECTOR."—At St. Columb (Cornwall) petty sessions on Feb 25th a man applied for a certificate of exemption from vaccination for his child on the grounds that he had a conscientious objection to the operation Five of the magistrates on the bench refused to sign the certificate; two, however, did so, holding that under the law they could not refuse, but they maintained that vaccination should be made compulsory.

HEALTH OF BATH RURAL DISTRICT.—Mr. C. Harper, the medical officer of health, in his annual report of the Bath Rural District, states that the population of the district is 27,764 and the area of the district 27,266 acres. During 1901 there were 327 deaths registered, corresponding to a death rate of 11 7 per 1000, as against 11·8 in 1900; 673 births were registered, equal to a birth-rate of 24·2 per 1000, compared with 24 3 in the previous year.

VACCINATION RETURNS.—The vaccination returns issued by the Barnstaple Board of Guardians for the first six months of 1901 state that in the Barnstaple district 207 births were registered, 163 successful vaccinations were performed, and 15 certificates of conscientious objection were granted, in the Ilfracombe district 188 births were registered, 141 successful vaccinations were performed, and 15 certificates of conscientious objection were granted; and in the Coombe Martin district 76 births were registered, 64 successful vaccinations were performed, and four certificates of conscientious objection were granted.

THE LATE DR T. R. LOMBE.—Dr. Thomas Robert Lombe died at his residence, Waldon Hill, Bemerton, Torquay, on Feb 23rd, in his 82nd year. Dr. Lombe received his medical education at St. Bartholomew's Hospital, taking the qualifications of M R C S Eng. and L.S A in 1843 and 1844 respectively He graduated as M D. of Aberdeen University in 1856 Dr Lombe had been for several years in practice at Torquay and was physician to the Erith House Institution for Invalid Ladies and consulting physician to the Western Hospital for Consumption. He took considerable interest in botany and his gardens at Bemerton contained many rare plants. The funeral, which took place on Feb 27th, was largely attended.

ROYAL LONDON OPHTHALMIC HOSPITAL.—The annual general meeting of the governors of this hospital was held on Feb 26th, in the board-room of the hospital Mr. H. P. Sturgis (chairman of the committee of management) presided and moved the adoption of the annual report. In doing so he stated that during the last year the institution had nearly 1900 in-patients and 31,200 new out-patients, which involved over 100,000 attendances He thought, therefore, that there could be very little doubt that the hospital was required. They were fortunate enough to have a grant made to them in January by King Edward's Hospital Fund to enable them to open 18 more beds Those beds were opened in January and were at once filled The grant would probably enable them to take in some 400 additional in-patients during the year There were 88 beds open at present, but still patients had to wait for several weeks before they could be admitted, except in cases of urgency, and he was confident that if they could open the 50 remaining beds they would be able to fill them to-morrow Referring to the efficiency of the hospital he pointed out that the institution had had strong testimony on this point from King Edward's Hospital Fund In the first place it had received a grant of £1250, which was the argest one received by any special hospital and the largest eceived by any hospital with the exception of two As to he financial position of the institution, he pointed out that iey required £5169 to clear the hospital from its debt on Dec. 31st last and also £8000 in further annual subscriptions r donations for the expenses of the current year He did ot see how it was possible to reduce the expenses, but he as certainly of opinion that such institutions ought to be relieved of the burden of rates. The report was unanimo adopted.

VACCINATION EXPENDITURE.—At a meeting of the St. Thomas (Exeter) Board of Guardians, held on F 28th, it was stated that the vaccination expenses for months amounted to £600

DEATH FROM ELECTRIC SHOCK.—On Feb. 28th at the Alhambra Theatre, Attercliffe, Sheffield, an electrician' labourer was amusing himself by swinging on an electric light bracket when it gave way and he received a fatal shock, a current of 200 volts passing through his body. At the inquest, which was held on March 3rd, the jury returned a verdict of "Accidental death."

HUNTERIAN SOCIETY.—The following gentlemen have been elected as officers of the society for the ensuing year:—President: Dr. A L Galabin. Vice-Presidents: Mr. H. J. Sequeira, Mr F. R Humphreys, Dr. W. Rawes, and Dr. W. A. Dingle. Treasurer: Dr. R. Hingston Fox. Trustees: Dr. H I. Fotherby and Mr. F. M. Corner. Honorary Librarian. Dr T. H. Arnold Chaplin. Orator: Mr. T H Openshaw. Secretaries: Mr. J. H. Targett and Dr. T Glover Lyon. Editorial Secretary: Dr. W. Rawes. Council Sir Hugh Beevor, Bart, M.D., Mr. J. S. E Cotman, Dr. A T. Davies, Dr. Fortesque Fox, Mr. A. W. Galloway, Dr. J Dundas Grant, Dr. E. W. Goodall, Dr. H V. Hickman, Mr J Kearney, Dr. J. W. Oliver, Dr. David Ross, and Dr J H Sequeira. Auditors: Mr. E. Gordon Brown, Mr. Hope Grant, Dr. G. Newton Pitt, and Dr. F. J. Smith.

THE ROYAL INSTITUTION.—Gold Mining in Klondyke formed the subject of the Friday evening discourse delivered in the Royal Institution on Feb. 28th by Professor Henry A Miers, who visited the district last August. An area of 20 miles square was occupied by the auriferous region, the streams in which radiated from a central mountain called the Dome Gold was obtained from gravel either in the bed of the valley or in the hill-side. In the latter situation it was reached by means of tunnels driven in horizontally In the valleys great difficulties arose from the fact that the gravel was covered by 10 or 15 feet of bog or peat, which was permanently frozen hard, and had to be thawed either by dropping hot stones into a hole, or by wood fires, or by steam heat. There was no crushing of gold-ore in Klondyke. Landscapes on view in the library of the institution contained references to extensive deposits of vanadium ores.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—A general court of the governors of this hospital was held on March 3rd at the Mansion House, when the Lord Mayor presided In moving the re-election of officers the Lord Mayor remarked that considerable extension of the site in the Waterloo-bridge-road had been rendered necessary by the increasing work of the hospital and additional land had been acquired in a great measure through the kindness and consideration of the Duchy of Cornwall and the influence and personal interest of the King. Last year the in-patients numbered 488, the out-patients 8044, and the operations 41 There were only 68 deaths during the year. The averag cost of each in-patient was £7 7*s.* 4*d.*, that of each be occupied £78, and that of each out-patient 2*s* 2*d.* £10,00 were required before the first half of the building operations could be carried out The motion having been adopted Mr. J T Richardson, the treasurer, said that a sum of £25,000 were required to make the building and extension scheme complete, and towards that amount about £9000 had been subscribed

EXAMINING BOARD IN ENGLAND BY THE ROYAL OLLEGES OF PHYSICIANS AND SURGEONS.—The following entlemen passed the First Examination of the Board in the bjects indicated at the January quarterly meeting of the xaminers:—

*Chemistry.*—Leonard Ernest Acomb, Middlesex Hospital; Gilbert Kennedy Awbery, King's College Hospital; Albert John Knowles Brayton, Owens College, Manchester, and University College, Liverpool; William Augustine Joseph Mingaye Briggs, Owens College, Manchester, and St. Thomas's Hospital; William Winsland Douglas Chilcott, Charing-cross Hospital; Robert Malcolm Coalbank, St Bartholomew's Hospital; George William Collinson, Yorkshire College, Leeds, and Halifax Technical School; George Herbert Curtis, Birkbeck Institute; Gurth Eager, King's College Hospital; Frans Gustaf Edholm, Birkbeck Institute; Lionel Gipps Hopkins Furber, Cambridge University, St. Bartholomew's Hospital, and Hartley College; William James Gifford Gayton, London Hospital, Howard Græme Gibson, Felsted School; Vivian Bartley Green-Armytage, University College, Bristol; Gerald Holroyde, Yorkshire College, Leeds; Thomas Jones Jenkins, University College, Cardiff; Valentine Goode Johnson, St. Mary's Hospital; Maurice Aloysius Kenny, Yorkshire College, Leeds; William Kenneth Kershaw, Owens College, Manchester, William Wilfred King, University College, Bristol, Albert Lawrence Loughborough, St Thomas's Hospital, Joseph Leopold Meynell, London Hospital; Alfred James Mundy, University College, Bristol; Edward Morgan, Frederick Morres, Charles Melton Ockwell, and Hubert Arnold Pallant, Guy's Hospital, David Phillips, St. Mary's Hospital; Frederic Eustace Leigh Phillips, London Hospital; Sri Krishna Raina, Allahabad University, Charing-cross and King's College Hospitals, and Birkbeck Institute, Harold Trenchard Rossiter, University College, Bristol and St. Thomas's Hospital; Harold Kenneth Salisbury, University College, Bristol; George Alan Simmons, St Thomas's Hospital, Frederick Smith, Firth College, Sheffield, Leslie Ernest Maule Smith, Charing-cross Hospital; Frank Harold Stephens St Mary's Hospital; Edmund James Fairfield Thomas, University College Bristol; Geoffrey Wacher, Guy's Hospital, John Grandisson Watkins, St. Bartholomew's Hospital, John Wells Whiteman, University College, Bristol; nd Albert Blagbrough Wolfenden, Yorkshire College, Leeds, and Halifax Municipal Technical School.

*Practical Pharmacy.*—Gilbert Kennedy Awbery, King's College Hospital, Frederick Barnes, Guy's Hospital; Hugh Frank Bodvel-Roberts, Cambridge University and St. Bartholomew's Hospital, Richard Burges, London Hospital; Arthur Hubert Davis, St George's Hospital, Cecil James Stewart Dismore, Guy's Hospital; Kenneth Alan Crawford Doig, Westminster Hospital, Charles Roland Babington Eyre, St. Thomas's Hospital, George Ernest Oswald Fenwick, Otago University and University College Hospital, Charles Aubrey Godson, St George's Hospital, Ernest Harrison Griffin, Cambridge University and Guy's Hospital, Robert George Ernest Grote, Charing-cross Hospital, Charles John Hope Gunning, St. George's Hospital; George Read Hannon, King's College Hospital, Henry Francis Hatfield, Guy's and St. Bartholomew's Hospital, George Wykeham Heron, Westminster Hospital, Archibald Edward Hills and Edward Torriano Holland, St Thomas's Hospital, Basil Hood Charing-cross Hospital, Philip Reginald Humphry and Mark Oliver Hunter St George's Hospital, Edgar Joseph and John Alfred Laughton, Charing-cross Hospital, Richard Ernest Howell Leach and George Mackenzie Lester Lester Oxford University and St. Thomas's Hospital, George Murray Levick, St. Bartholomew's and University College Hospitals, Hamish Nicol, Westminster Hospital, Bryan Pick, St George's Hospital Carl Henry Reinhold and Jules Frederick Rey, Guy's Hospital, Ernest Sydney Routly, St. Mary's Hospital, Malcolm Winfrid Shutte, St. George's Hospital, Charles Speers, St. Mary's Hospital, Frederick Morton Vincent Smith and Francis John Turner, Guy's Hospital; George Sydney Welham, Charing-cross Hospital, Frank Pilrod Whitehead, Ambrose Cyril Wilson, and Frank Herbert Wood St. Bartholomew's Hospital, and George Ernest Wood, St Mary's Hospital.

*Elementary Biology.*—Robert Nicholas William Biddulph, University College, Bristol; Albert John Knowles Brayton, Owens College, Manchester, and University College, Liverpool, Archibald Cordon, Mason College, Birmingham, Henry Drysdale Dakin, Yorkshire College, Leeds, Llewellyn Etter Davies, University College Liverpool, Herbert Alfred De Pinna, Middlesex Hospital; Francis Carminow Doble and Gurth Eager, King's College Hospital; Howard Græme Gibson Felsted School; William Robert Greening, Guy's Hospital; Cyril Verity Griffiths, King's College Hospital, John Keith Anderson Helm and Herbert John Hills, Guy's Hospital, Hugh George Hobson Middlesex Hospital; Gerald Holroyde, Yorkshire College Leeds, Charles Metheson Kennedy and John Iles Francis Knight, London Hospital, Thomas Gordon Lewis, King's College Hospital; Albert Lawrence Loughborough, St Thomas's Hospital; Percy John Lush, London Hospital, Oscar Le Fevre Milburn, Birkbeck Institute, Malcolmson Knox Nelson University College, Belfast, John Harry Mayston, Edward Morgan Gerald Hamilton Morris, George Rumsey Phillips, Edward Ebenezer Rendle, and Arthur Tunna Rivers, Guy's Hospital Cecil Frank Rumsey, Charing-cross Hospital, Gilbert Bailey Scott St Bartholomew's Hospital; Gerald Noel Boyd Sebastian St George's Hospital; Sidney Slade, Middlesex Hospital, Frederick Smith, Firth College, Sheffield, Herbert McLean Staley, Owens College, Manchester; Richard Henry Easington Stevens, University College Hospital, Arthur Westray Swinburne, Yorkshire College Leeds; Arthur Christopher Watkin, University College Hospital; Reginald Willan, Guy's Hospital, and John Dill Williams, University College, Belfast.

The following gentlemen passed the Second Examination of the Board at the quarterly meeting of the examiners:—

*Anatomy and Physiology.*—Wilfrid Godwin Attenborough, King's College Hospital; José Maria Barrionuevo and Arthur Morris Benett, Guy's Hospital; Charles Murchison Bernays, St Thomas's Hospital; John Braybrooke Binns, St. Bartholomew's Hospital; William Bowater, Mason College, Birmingham; Herbert Alfred Bodkin and Leonard Howard Bowkett, London Hospital; Robert James Brogden, University College, Cardiff; George Hammond Cheyney, Guy's Hospital, George Percival Charles Claridge and Patrick Duncan MacIver Campbell, St. Mary's Hospital; Thomas Alexander Clarke, King's College Hospital; Owen Cunningham Preston Cooke, London Hospital; Hugh Palliser Costobadie, Guy's Hospital, James Alexander Cowie, B.A., B Sc., New Zealand, Otago, and Glasgow Universities; John Rees Davies, University College, Cardiff, Alban Dixon, St. Mary's Hospital; Edmund Michael Dolan, Yorkshire College, Leeds; Percy Albert Stanley Dyson, Guy's Hospital; Stephen Field, St. Mary's Hospital; Eustace Stanley Hayes Gill, University College, Liverpool; Henry Gray, St. Bartholomew's Hospital; Arthur Donald Griffith, King's College Hospital, Edwin Claude Hayes, St. Bartholomew's Hospital; Samuel Clifford Hayman, University College, Bristol; Frederick Charles Hepburn, Cambridge University; Robert Rutson James, St George's Hospital; Harold Ernest Kitchen, B A, Cambridge and Owens College, Manchester; Arnold Leeming, Guy's Hospital; Archibald Smith Littlejohn, B A., Cambridge and Guy's Hospital, Sidney Hirst Lockwood, St. Mary's Hospital; Conrad Loddiges, St Bartholomew's Hospital; Frederick James Macphail, University College, Liverpool; Edgar William Matthews, King's College Hospital, Frederick William Morgan, University College, Bristol, Ernest Blommart Miles, Hugh Francis Fountain Mortimer, William George O Malley, London Hospital; Arthur O Neill, St Bartholomew's Hospital; Hugh Falkenberg Powell, University College, Hospital; William Hugh Prendergast Parker, University College, Cardiff; Harold Edgar Priestly, St. George's Hospital, Leslie Rawes and Harold William Read, St. Thomas's Hospital, Frederick John Rees, Calcutta Medical College, Walter Reeve, Guy's Hospital; Frank Melville Pitcairn Rice, St Bartholomew's Hospital; Philip Meredith Roberts, University College Hospital; Edwin Walter Routley, Guy's Hospital, Albert Salmon and Ernest Littleton Sandiland, London Hospital, Gerald Maberley Taylor and William Reginald Margetts Turtle, London Hospital, Theophilus Ralph Waltenburg, M A, Oxford, and Owens College, Manchester, Frederick Weber, St. Bartholomew's Hospital, Leonard White, Westminster Hospital; Trevor Hamilton Watkins and William John Wilkinson, St Thomas's Hospital, Ernest Douglas Wolff, King's College Hospital, and Walter John Weston, St. George's Hospital.

*Anatomy only.*—Urban Morris Asplen, King's College Hospital; and Wilfrid Robert Pagen, London Hospital.

*Physiology only* —John William Wynne Hogan, Madras Medical College, and Charles Frederick Stileman, St. George's Hospital.

UNIVERSITY OF CAMBRIDGE.—The following degrees were conferred of Feb. 27th:—

*Doctor of Medicine* —G H. Goldsmith, Gonville and Caius.

*Bachelor of Medicine and Bachelor of Surgery.*—J. S. Steele Perkins, St John's

*Bachelor of Medicine* —J L Timmins Emmanuel

*Bachelor of Surgery* —J E. W. Cole, Corpus Christi.

CAPTAIN E T. INKSON, V.C., R.A.M.C., was entertained at a complimentary dinner given in his honour by the Union Society of University College and Hospital on Feb. 21st, in recognition of his distinguished services in the South African war. The dinner took place at the Café Royal, Regent-street, London, W., and Dr. Vivian Poore occupied the chair. There were over 150 guests present and the proceedings were marked with the utmost enthusiasm Among those present were Mr. Christopher Heath, Dr J. Rose Bradford, Dr. Herbert R. Spencer, Dr Dudley W. Buxton, Dr Vaughan Harley, Mr. Victor Horsley, Lieutenant-Colonel W Babtie, V.C., C.M.G, R.A M C., Sir J. R. A. Clark, Bart., R.A.M.C., Mr. A. E. J. Barker, and Mr. Raymond Johnson. After the usual loyal toasts had been duly honoured Mr. Christopher Heath proposed the toast of "The Services," which was responded to by Lieutenant-Colonel Babtie. The chairman then proposed the health of the guest of the evening, Captain Inkson, V C., and read the following extract from the official statement regarding the act for which that officer received his decoration: "On the 24th of February, 1900, Lieutenant Inkson, R.A.M.C, carried Sec. Lieutenant Devenish (who was severely wounded and unable to walk) for three or four hundred yards under a very heavy fire to a place of safety The ground over which Lieutenant Inkson had to move was much exposed, there being no cover available." The chairman also reminded his audience that General Buller in his official despatches had referred to the habitual gallantry displayed by Captain Inkson. In responding to the toast Captain Inkson thanked the Union Society of University College and Hospital for the honour they had paid to him and with some difficulty was persuaded to give a short account of the active service which he had seen in South Africa.

it does not seem to me necessary to take any general steps with regard to it. I may point out, however, that in any such case it is open to the guardians to terminate their contract with the public vaccinator by giving him 28 days' notice."

*Death after Vaccination.*

Mr. CORRIE GRANT asked the President of the Local Government Board if his attention had been called to an inquest before Dr. G. Danford Thomas on Jan. 31st into the death of Mr. Essex after vaccination; was he aware that Mr. Essex was vaccinated on Jan. 15th, and died on the 26th from blood-poisoning; whether the lymph from which he was vaccinated was supplied by the Local Government Board, and whether five other gentlemen vaccinated at the same time from the same lymph were seriously ill; whether the vaccination was from calf lymph No. 1538; and whether anything was known of the history of this lymph.—Mr. LONG replied: The answer as regards the first three points is in the affirmative. The jury at the inquest found that Mr. Essex died from "coma and septic meningitis, the septic condition occurring after vaccination, from some external infection, from natural causes." They added that they were "satisfied that the vaccination was duly and properly performed." By my direction one of the medical inspectors of the Local Government Board attended the inquest and subsequently made further inquiry into the matter, and he concurred in the view taken by the jury. I am not aware that any of the five other persons referred to were seriously ill as suggested. In only two of the cases does there appear to have been any trouble and in both of these the inspector ascertained that the arm was healing satisfactorily. The lymph was from calf No. 1538 and was used in the vaccination of a large number of persons besides those mentioned and no ill-effects have been reported.

*London Water Bill.*

This Bill was read a second time and referred to a Joint Committee of the two Houses of Parliament, who will have power to hear counsel and witnesses on behalf of the various interests concerned.

TUESDAY, MARCH 4TH.

*The Influenza Epidemic.*

Mr. HENRY HOBHOUSE asked the President of the Local Government Board if, in view of the spread of the influenza epidemic and the uncertainty that prevails as to its causes and conditions, he would consider the appointment of a small commission of experts to investigate and report upon the subject.—Mr. GRANT LAWSON, in the absence of Mr. LONG, replied: The causes and conditions of influenza have already been investigated by the medical staff of the Local Government Board and by experts employed for the purpose, and two lengthy reports on the subject have been issued by the department. In these circumstances it does not appear to me that any good results would follow from a further investigation of the kind suggested by my hon. friend.

Mr. RUTHERFORD asked the First Commissioner of Works if he would make arrangements whereby a sample of the atmosphere of the House during its sitting could be taken for the purpose of analysis and report thereon.—Mr. AKERS-DOUGLAS replied that he had given instructions that this should be done.

Dr. FARQUHARSON asked the right hon. gentleman whether he would take into consideration the advisability of reappointing the select committee which sat on the ventilation and drainage of the House. The committee could take expert evidence and report generally as to the sanitary condition of the House.—Mr. AKERS-DOUGLAS replied that the committee of last session recommended the appointment of a Ventilation Committee, and this recommendation had been acted upon.

*The Army Medical Service.*

Mr. BRODRICK, in introducing the Army Estimates of the year, made a statement with reference to the reform of the Army Medical Service. Last year, he said, he had the advantage of the assistance of several of the very best civil practitioners in London in drawing up a new scheme for this service. The features of that scheme were that they improved the pay and increased the number of officers. They proposed to give zealous officers the opportunity of leave for study and to provide the means for that, if possible, within the metropolis. They carried out by examinations the principle of promotion by merit, which was all-important in the medical service. They hoped for an interchange with the civil schools by bringing these officers into close touch with the civil schools. They proposed that the continual change of quartering of medical officers should be checked and that as much as possible they should be kept in the same quarters for two years, and they proposed at the beginning of a man's service to attach the man to the battalion and thus to give him a home. He knew that a notice of motion had been given on this subject, but he believed that he should be able to satisfy the House that nothing that the wide experience of civil practitioners could bring to bear on the new system had been lost sight of in drawing it up. With the reform of the medical service was connected the reform of the nursing service, a warrant for which would be issued in a few days. They had got the advantage of the actual and practical assistance as president of the new nursing service of Her Majesty the Queen. He attached great importance to that assistance, not merely from the fact of the exalted position of Her Majesty, but because Her Majesty had a practical knowledge and personal acquaintance with nursing which were enjoyed by few women in the kingdom, and he believed that in selecting nurses for the army service the board which they were about to form would be as efficient a one as could be obtained.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ADAMS, JOSEPH DIXON, M.D. St. And., M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health by the Yeovil Rural District Council.

AUSTEN, HAROLD, M.D., B.S. Lond., M.R.C.S., L.D.S. Eng., has been appointed Lecturer on Materia Medica to the Royal Dental Hospital of London.

CALEY, J. W., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medica Officer of Health for the Riccall Sub-district of Selby, Yorkshire.

DRINKWATER, JAMES PRATCHETT, M.R.C.S., L.S.A., has been appointed Medical Officer of Health to the Llangollen District Council.

DRYLAND, J. W., M.R.C.S., has been re-appointed Medical Officer of Health to the Kettering Urban District Council.

FULCHER, G. F., M.B., M.S. Edin., has been appointed Medical Officer of Health to the Chingford Urban District Council.

GRIERSON, J. T., M.B., B.Ch. Vict., has been appointed to the City Hospital, Park-hill, Liverpool.

HALL, ALFRED, M.R.C.S., has been re-appointed Medical Officer of Health to the Mayfield Rural District Council, Derbyshire.

HUMPHRY, R., M.R.C.S., L.R.C.P. Edin., has been appointed Medical Officer of Health for the City of Chichester.

MILLER, J., M.R.C.S., L.R.C.P. Lond., has been appointed to the City Hospital, Fazakerley, Liverpool.

MILLER, J. W., M.B., Ch.B. Vict., D.P.H. Cantab., has been appointed Assistant Medical Officer to the City of Liverpool Hospitals for Infectious Diseases.

NESBITT, C., M.D. R.U.I., has been appointed Certifying Surgeon under the Factory Acts for the Randalstown District of the County of Antrim.

SOPER, G. MORGAN, M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the Royal Albert Hospital and Eye Infirmary, Devonport.

SWORDER, E. G., M.B., B.C. Cantab., has been appointed Honorary Medical Officer to the St. Andrews Convalescent Home, Folkestone, vice Cecil Latter, deceased.

SYMONS, ROBERT FOX, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for Pretoria and District and Assistant Medical Officer of Health for the Transvaal.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BELGRAVE HOSPITAL FOR CHILDREN, 77 and 79, Gloucester-street, S.W. —House Surgeon for six months. Board and lodging provided and a gratuity of £5.

BIRMINGHAM GENERAL DISPENSARY.—Resident Surgeons, unmarried. Salary £150 per annum (with allowance of £30 for cab hire), furnished rooms, fire, lights, and attendance.

BIRMINGHAM TAME AND REA DISTRICT DRAINAGE BOARD.—Bacteriologist. Salary £160 per annum.

BRADFORD POOR-LAW UNION.—First Resident Assistant Medical Officer, unmarried. Salary £125, with rations, apartments, and washing

BRADFORD ROYAL INFIRMARY.—Dispensary Surgeon, unmarr Salary £100 per annum, with board and residence.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 a year, w board and residence.

BRIGHTON, HOVE, AND SUSSEX THROAT AND EAR HOSPITAL, Churc street, Brighton.—House Surgeon for six months, renewabl Salary at rate of £75 per annum.

BRISTOL GENERAL HOSPITAL.—Assistant House Physician. Salar £70 per annum, with board and residence. Also Assistant Hous Surgeon.

CARDIFF INFIRMARY.—Assistant House Surgeon, also Assistant House Physician, both for six months, renewable. Salaries at rate of £75 per annum, with board, washing, and apartments.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer. Salary £120, rising to £150, with board, apartments, &c.

DORSET COUNTY HOSPITAL, Dorchester.—House Surgeon. Salary £100, with board and residence.

DUNDEE ROYAL INFIRMARY.—Two Resident Medical Assistants for six months. Salary at rate of £40 per annum, with board and washing.

EAST SUSSEX COUNTY ASYLUM, Hayward's Heath.—Second Assistant Medical Officer and Pathologist, unmarried. Salary £175 per annum, with board, lodging, washing, and attendance.

ESSEX AND COLCHESTER GENERAL HOSPITAL.—House Surgeon. Salar £100 a year, with board, washing, and residence.

FISHERTON ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, lodging, and washing.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.—Junior House Physician for six months. Salary at rate of £30 per annum, with board, lodging, and washing.

GREY'S HOSPITAL, Pietermaritzburg, Natal, South Africa.—Resident Medical Superintendent. Salary, £350 first year, £400 second year, with board, lodging, and washing.

JESSOP HOSPITAL FOR WOMEN, Sheffield.—House Surgeon (unmarried). Salary £75 per annum, with board, lodging, &c.

KENT COUNTY OPHTHALMIC HOSPITAL, Maidstone.—House Surgeon. Salary £100, with board and residence.

LANCASHIRE COUNTY ASYLUM, Winwick, Warrington.—Assistant Medical Officer, unmarried. Salary £150 per annum, rising to £200, with apartments, board, attendance, and washing.

LEEDS UNION WORKHOUSE SCHOOLS AND INFIRMARY, Beckett-stre Leeds.—Assistant Medical Officer, unmarried. Salary £130 p annum, rising to £150, with board, washing, apartments, a attendance.

LEICESTER INFIRMARY.—Honorary Assistant Physician.

LIVERPOOL WORKHOUSE, Brownlow-hill.—Assistant Medical Officer, unmarried. Salary £80 per annum, with rations, and fees £20.

LONDON LOCK HOSPITAL, Harrow-road, W.—Anæsthetist.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician and House Surgeon, with salary at rate of £40 a year each; Assistant House Physician and Assistant House Surgeon, with salary at rate of £20 a year each. All tenable for six months.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL, Grafton-street, Tottenham-court-road, W.—Clinical Assistants.

### *Royal Commission on Tuberculosis.*

The financial provision for this commission for the year ending March 31st, 1903, is as follows—viz , secretary, £400 ; clerical assistance, £104 , messenger, £36 , travelling expenses, £500 , shorthand writing, £150 ; incidental expenses, £150 ; and scientific investigations, £12,000.

### *Laundries and Factory Legislation.*

A Bill introduced by the Earl of Lytton, bringing laundries within the scope of factory legislation has been read a second time in the House of Lords. There is little chance, however, of its passing into law, for the Government has intimated that it is not prepared to give it facilities in the House of Commons where it is sure to meet with strenuous opposition from Members interested in religious institutions carrying on laundry business It was the opposition of these Members which caused Mr. Ritchie to abandon the laundry clause in the Factory and Workshop Bill of last session

### *Midwives Bill*

Preparations are now being made for the consideration of the Midwives Bill, by the Grand Committee on Law. At the beginning of each session of Parliament this committee is set up with a certain strength of Members, but when a Bill is referred to it the Committee of Selection nominates additional Members to take part in the discussion of that particular measure. In the case of the Midwives Bill the following 15 additional Members have been so nominated—viz , Mr. Ambrose, Mr Griffith-Boscawen, Mr. John Burns, Mr. Caine, Mr. Emmott, Sir Michael Foster, Sir Walter Foster, Mr. Heywood Johnstone, Lord Cecil Manners, Mr. T. P. O Connor, Colonel Sadler, Mr Schwann, Sir Barrington Simeon, Sir John Tuke, and Mr. Eugene Wason. In anticipation of the proceedings of the Grand Committee Sir John Tuke has given notice of a number of amendments One of these proposes to make it an offence for an uncertified woman habitually and for gain to attend cases of childbirth and another to subject to the approval of the General Medical Council the rules framed by the Central Midwives Board instead of having them, as the Bill proposes, "subject to the approval of the Privy Council after consultation with the General Medical Council." With regard to the licence question, Sir John Tuke proposes to insert these words—viz "No woman shall hold herself out as a practising midwife in any county or county borough without having previously obtained from the local supervising authority a licence enabling her to practise therein, which licence shall be granted on proof by the woman that her name is on the midwives roll The licence shall remain in force till the thirty first day of December following, and shall be revocable at any time by the local supervising authority in case the holder be proved to the satisfaction of the Central Midwives Board to have infringed any of the regulations framed under this Act The licence shall be issued on payment of a fee of one shilling, it shall only be available in the county for which it is issued, and it shall be renewed annually on the first day of January. The Grand Committee will meet on Tuesday, March 11th, to take up the consideration of the Bill, with Sir James Fergusson in the chair.

---

## HOUSE OF COMMONS

### THURSDAY, FEB. 27TH.

### *Enforcement of the Vaccination Acts.*

Mr JACOBY asked the President of the Local Government Board whether he was aware that the goods of Gershom Squires and Jabez Hatfield of Wirksworth had been seized for the third time for recovery of the same amount of costs incurred under the Vaccination Acts, these men's goods having been seized and sold in July last, again seized to the value of £400 in December last, but not sold owing to failure on the part of the auctioneer, whether he could explain under what authority the third seizure was made, and if any action would be taken.—Mr RITCHIE replied: I am informed by the chief constable of Derbyshire that the defendants named were ordered in December, 1900, and January, 1901, respectively to pay the costs of orders under the Vaccination Acts and refused to pay The warrants were only partially enforced at the first distress owing to the action of persons in sympathy with the defendants, and on the second occasion in December the auctioneer failed to attend. The police have now taken further steps to recover the amount due I have neither the authority nor the desire to interfere with the enforcement of the law.

### *Richmond Hospital, Dublin.*

Mr PATRICK JOSEPH O BRIEN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that a claim for £30 had been made on the guardians of Nenagh Union by the governors of Richmond Hospital, Dublin for the maintenance and treatment of pauper patients sent from the Nenagh workhouse to Richmond Hospital in the year 1900, although paupers from this union had been sent to Richmond Hospital for treatment of special cases for upwards of 30 years prior to 1895 without claim for payment by the hospital authorities, whether he was aware that at the said date a bill was furnished to the guardians for maintenance of pauper patients for two years, but which they repudiated on the ground that the hospital, being maintained by Imperial grant, was bound to receive patients free of charge; whether he was aware that since that time the hospital continued to receive the Board's special cases without question till about 12 months ago, when the claim in question was made for which the governors were now pressing for payment; and seeing that this hospital was bound by its charter to receive pauper patients free, would he advise them to do so.—Mr. WYNDHAM replied The authorities of this hospital are not aware that patients were maintained prior to 1895 without payment. The guardians declined to make any payment in November of last year There is no obligation attaching to the conditions upon which the Parliamentary grant is paid to the hospital that pauper patients shall be maintained gratuitously. I may point out that the expenditure incurred by the Richmond and other hospitals in respect of public grants is not covered by such grants.

### *Sophistication of Butter.*

Mr. O SHAUGHNESSY asked the President of the Board of Agriculture whether he was aware that considerable quantities of a material known as milk blended butter were now made by working milk into butter by a mechanical process whereby the amount of water in the original butter was increased from a relatively small proportion up to 20 or 25 per cent , and that quantities of foreign butter thus treated were sold monthly and what steps he would take to prevent this practice —Mr. HANBURY replied that he was aware of this practice Its legality was now before the law courts and he must await their decision before he could properly deal with the subject by an amendment of the law or otherwise As soon as he had had an opportunity of considering the evidence submitted to the Departmental Committee on Butter he would fix a standard, and he hoped that that in itself would go far to meet the difficulty which had arisen.

### *Vaccination in France and Germany*

Mr COGHILL asked the President of the Local Government Board whether his attention had been called to legislation recently passed in France and Germany with the object of making vaccination and revaccination compulsory on all the population in these two countries; and whether he had any information as to the success of such legislation in diminishing the number of cases of small pox.—Mr. GRANT LAWSON answering for Mr LONG, said: I understand that under a law made this month vaccination and revaccination will be rendered compulsory in France In Germany vaccination and revaccination have been compulsory on the population generally since 1874. Information obtained by the Royal Commission on Vaccination and referred to in their report, shows that the system has been highly beneficial in diminishing small pox

### FRIDAY FEB 28TH.

### *The Fees of Medical Witnesses.*

Mr BOWLES asked the President of the Local Government Board whether the instructions given to the auditors with respect to payment of fees by a coroner to medical witnesses under Section 22 of the Coroners Act, 1887 necessitated the disallowance of all fees to medical practitioners who acted gratuitously as medical officers at a hospital infirmary or other medical institution, and whether, if a medical officer attached himself to act gratuitously at any such institution, he was entitled to be paid the fees specified in the said Section 22 of the said statute —Mr GRANT LAWSON, replying for Mr. LONG, said: The Local Government Board has not given any instructions to district auditors on the subject referred to by my hon. friend. It rests with the auditor in any case to decide whether a particular payment is illegal and therefore one to be disallowed The Board's jurisdiction arises only on an appeal from his decision. A question of this sort was considered in 1893 by the Board and the Secretary of State The view taken was that the medical officer of an institution to which the section applied would not be entitled to the fee in question, although he received no pay for performing the duty of medical officer —Mr BOWLES Has that changed the procedure prior to 1893?—Mr. GRANT LAWSON The question had not arisen prior to 1893 That was the decision given in a case then brought before the Board and the Home Office

### *Army Medical Department*

Mr BRODRICK, in reply to a question by Sir JOHN TUKE, said that the warrant bearing on the reconstruction of the Army Medical Department would be issued before the vote for the department was taken

### *Influenza among Members*

Mr DILLON asked the Chancellor of the Exchequer, as acting leader of the House whether he had turned his attention to the necessity of doing something to disinfect the House against the influenza. The casualty list was already heavy and no Member knew the moment when he might be struck down He should have imagined that the experience of the members of the Government themselves would have been enough to turn their attention to this matter. He suggested to the Chancellor of the Exchequer the advisability of asking an informal committee of the medical men who were Members of the House to consider the matter and to report whether in their opinion anything could be done to protect themselves and their fellows from this poisonous atmosphere. Failing that he should ask permission to submit a motion that the House should adjourn for a week in order that the House might be disinfected.—Sir MICHAEL HICKS BEACH said that if any members had suffered from the influenza it was those who sat on the Treasury Bench If it were possible to find a remedy no Members would be happier than the Ministers, but he was not prepared to say that this House was the only place where they were exposed to infection. He would, however, make inquiries and see whether anything could be done

### *Lead poisoning in the Pottery Trade.*

In the course of a debate on this subject Mr. RITCHIE announced that rules have now been agreed upon. They have been submitted to Lord James of Hereford and have received his assent, and the Home Office proposes to circulate them among manufacturers with an expression of the hope that advantage will be taken of them

### MONDAY, MARCH 3RD

### *Vaccination Fees*

Mr CORRIE GRANT asked the President of the Local Government Board whether one of the public vaccinators of the Battle district, Sussex, had charged the guardians fees for the vaccination of certain persons after he had already charged fees to the persons vaccinated for his services, if so could he state in how many cases this had occurred, and what steps he had taken or proposed to take, with regard to this public vaccinator and to prevent the practice occurring elsewhere —Mr LONG replied I understand that the officer referred to in the question included in his register of persons vaccinated for the quarter ended June last the names of three persons for whose vaccination he was paid as their private medical attendant He thus contravened Section 22 of the Vaccination Act 1867 On finding this to be the case he appears himself to have drawn the attention of the guardians to the matter and returned to them the fees they had paid him for the three vaccinations. I have only received the officer's explanation within the last few days and I am still in communication with the guardians on the subject I have no reason to suppose that the practice complained of prevails, and

### NEGLIGENCE AND BAD MEAT.

A NORFOLK farmer was recently fined at the Guildhall Police-court £25 and £4 costs for being the owner of a sheep which was deposited in the Central Meat Market for the purpose of sale, being unfit for food. His case differs from ordinary cases of the wilful exposure of unsound meat in that there was nothing to show that the defendant knew, or might have known, that the sheep was diseased, and no evidence that he had seen the carcass after it was slaughtered. Indeed, the defendant gave evidence that he had not seen the carcass and was entirely ignorant of its condition, and the Alderman expressed his belief that this was the case He pointed out, however, that ignorance in such a case does not constitute a defence in point of law, and the heavy fine inflicted will show owners of dead meat that ignorance avails but little as a plea in mitigation of punishment. The duty, in short, is imposed upon the owner of meat exposed for sale as food to see that it constitutes wholesome food, and the penalty is imposed on those who do not perform that duty, whether the omission is the result of a deliberate determination to pass off good meat as bad or simply of neglect to ascertain its quality.

### THE LITERATURE OF CANCER.

*To the Editors of* THE LANCET.

SIRS,—I should be much obliged if any of your readers could give me references to any old books on cancer, especially to books containing accounts of obsolete methods of treatment.

I am, Sirs, yours faithfully,
F.R.C.S.

March 4th, 1902

### THE REV ROWLAND HILL AND VACCINATION.

THE Cardiff *Western Mail* of Feb 28th contains the following paragraph under the heading "Interesting Items of News Current 100 Years Ago"

"August 1807 —The Rev Rowland Hill, who had been preaching to very large congregations at Haverfordwest and its vicinity, has also continued his efforts to promote the vaccine inoculation with success. During this and a former visit about two years ago he has applied the protecting lancet to no less than 1500 subjects After the most diligent inquiry not one instance of failure has yet been recorded

### THE YARMOUTH BOARD OF GUARDIANS AND THEIR WORKHOUSE MEDICAL OFFICER.

THE relations of the Yarmouth Board of Guardians to their workhouse medical officer are at present peculiar The issues are rather confused, but from the report in the *Yarmouth Mercury* of Feb. 22nd of the meeting of the guardians held on Feb. 17th the matter appears to stand thus A sub committee had been appointed to consider the medical officer's contract Under this contract he received £140 per annum the board finding instruments and appliances. The sub committee recommended that the medical officer, Dr H. Collier, should in future provide his own instruments and appliances, but that his salary should be increased by £25, making it up to £165. The report of the sub-committee on being presented to the board was negatived by 11 votes to seven The chairman then moved that the altered contract be approved, but that no increase in salary be given This was agreed to, so that now apparently Dr Collier will have to provide his own instruments and appliances and still get only £140 per annum We await developments with interest.

◆

*Abernethian* —We are not prepared to give a legal opinion A legal decision would depend upon the terms of contract as settled by any letters between the parties, and perhaps by evidence as to custom We can only recommend that no steps should be taken before consulting a lawyer We would point out that there ought to be no disposition to exact the uttermost from the employer, he appears to have had to pay his sick assistant, his sick locum tenent, and his sound locum tenent all at the same time

*Inquirer* (1) —A Manual of School Hygiene, by Edward W Hope, M D, and Edgar A Browne, F R C S Edin, Cambridge University Press, 1901, price 3s 6d School Hygiene, by Edgar R Shaw, Professor of the Institute of Pedagogy, New York University, Macmillan and Co, London and New York, price 4s 6d Handbuch der Schulhygiene, von Dr Adolf Baginsky, published by Ferdinand Enke 1898.

*Medical* —The General Medical Council have definitely stated their objection to medical aid associations where canvassing is carried on, and have acted upon their objection If there is no canvassing the Council might see no harm in the clubs in question, yet to act as medical officer to them might not be in the interests of the public, the medical profession or the medical officer

*Inquirer* (2) —If our correspondent will send us the rules prospectus, &c., of the association we will advise him in the matter Hardly any medical aid association is to be completely commended from a professional point of view, but some are better than others

*Venienti occurrite morbo* —The idea is thoroughly sound and has been tried, but unfortunately the preventive, to be strong enough to do its work, is sure to have sufficient irritative properties to make it uncomfortable for constant and regular application

*Morality.*—We should point out that the main question is one the persons concerned must answer for themselves. To give advi practically to allow that something should be done, an attitude w a medical man must be chary of adopting.

COMMUNICATIONS not noticed in our present issue will receive attent in our next.

## Medical Diary for the ensuing Week.

### OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY** (10th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. # Births, Marriages, and Deaths.

## BIRTHS.

DOWDING.—On Feb. 25th, the wife of Ernest F. C. Dowding, M.R.C.S., L.R.C.P. Lond., of a son (prematurely).

EDE.—On Feb. 23rd, the wife of G. Hubert Ede, M.D. Aberd., of a daughter.

GREEN.—On March 1st, the wife of Howard Green, M.R.C.S., L.R.C.P. Lond., of a son.

HAWTHORNE.—On Feb. 17th, at "Warrawee," Mudgee, New South Wales, the wife of E. Sydney Hawthorne, F.R.C.S. and L.R.C.P., of a daughter.

KENDALL.—On March 2nd, the wife of Nicholas Fletcher Kendall, M.R.C.S., L.R.C.P. London, of a son.

MOIR.—On Feb. 27th, the wife of Major James Moir, R.A.M.C., M.B., B.S. Aberd., of a son.

TAYLOR.—On Feb. 23rd, the wife of Sidney Johnson Taylor, M.B. Edin., M.R.C.S., of a son.

YOUNG.—At Herbertfield, Hamilton, on the 5th inst., the wife of James Murray Young, M.B. Glasg., of a son.

## MARRIAGE.

RAMSAY—CREE.—On Feb. 25th, at the British Residency, Baghdad, Turkish Arabia, Captain G. Ramsay, I.M.S., to Agnes, fourth daughter of the late Mr. W. S. Cree of Glasgow.

## DEATHS.

BERDOE.—On Feb. 28th, at Tynemouth House, Victoria-park-gate, N.E., Mary, the dearly-loved wife of Edward Berdoe, M.R.C.S., &c.

FISHER.—On the 1st March, at Sittingbourne, Kent, Caroline Maud Irene, wife of H. Holdrich Fisher, M.D., of influenza, complicating recent confinement.

JOHNSON.—At Evandale, Tasmania, on Jan. 22nd, John George Johnson, M.R.C.S. Eng., L.R.C.P. Lond., aged 44 years.

KNILL.—On March 2nd, at Heathfield, Bexhill, James Knill, L.R.C.P. Edin., M.R.C.S., aged 68 years

LOMBE.—On Feb. 23rd, at Torquay, Thomas Robert Lombe, M.D. Aberd., aged 81 years.

MYERS.—On March 3rd, 1902, at Birnam, 1, Kent-gardens, Ealing, W., Laura Isabelle (née Bartlett), the beloved wife of Lieutenant-Colonel H. R. Myers, V.D., *late Surgeon 19th Middlesex (Bloomsbury) Rifles.* Funeral service at St. Stephen's, West Ealing, on Saturday, 8th inst., at 12.30 P.M. Interment at Highgate (New) Cemetery at 2.30 P.M. Friends will please accept this (the only) intimation.

SIMPSON.—On Feb. 25th, at Darnley-road, W., Maxwell Simpson, M.D., LL.D., F.R.S., in his 87th year.

TALBOT.—On Feb. 23rd, at Dorset County Hospital, Dorchester, Ashley West Talbot, B.S., L.R.C.P. Lond., M.R.C.S. Eng., aged 25 years

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## CHEAP RATES.

*To the Editors of* THE LANCET.

SIRS,—The inclosed was lately sent to me in company with a postal order for 2*s.* 6*d.* For this munificent fee I was expected to make an examination and report equivalent to that required by a high-class life assurance office. I promptly returned the fee and declined the honour. No wonder the profession is exploited by the public as it is when men can be found to do this sort of work at the price considered adequate.

I am, Sirs, yours faithfully,

March 1st, 1902. EAST ENDER.

[INCLOSURE.]

SURREY REFORMED BENEFIT SOCIETY.

Feb 10th, 1902.

*Dear Sir,—An Applicant for Membership of the above Society will wait upon you for Medical Examination. Will you kindly oblige.*

*Yours respectfully,*

*A. J. Clemo, Secretary.*

SURREY REFORMED BENEFIT SOCIETY.

*Office:* WALWORTH, LONDON, S.E.

*Secretary's Address:* A. J. CLEMO, SECRETARY, 171, ALBERT-ROAD, PECKHAM, LONDON, S.E.

MEDICAL REFEREE'S REPORT

*On the health of .....................Proposed for Membership in the above named Society.*

*It is requested that as this report is a strictly confidential statement, the Referee will kindly forward it direct to the Secretary, and not to communicate its purport to the Candidate, or to any other person.*

*The Referee is also requested to obtain the signature of the person to be examined before proceeding with the examination, in order to establish his identity.*

*I acknowledge that I have this day submitted myself to Dr. .......... ..... .. for Medical Examination.*

*Signature* ............. .. .. ...

*Date*........ .. . .. ., 18... *Address*..... ... ... ..... .....

QUESTIONS.

*A*—What is the personal appearance and general conformation of the candidate?

*B*—What is his apparent age?

*C*—Have you any reason to suspect irregular or intemperate habits?

*D*—Is the candidate the subject of hernia, and, if so, are you satisfied a proper truss is worn?

Has he any physical defect or infirmity?

*E*—Has the candidate suffered from asthma, bronchitis, gout rheumatic fever, fistula, sexual disorder, or any serious illness? If so, please state date and duration of last attack, and whether in your opinion, the health is affected thereby.

*F*—Are the veins enlarged in any part, or varicose?

*G*—Are there any external signs which indicate abscess?

*H*—Is there any reason to apprehend paralysis, epilepsy, apoplexy, or insanity?

*I*—Is there any reason to suspect liver or kidney disease?

*K*—Are the heart and lungs normal in every respect, and perfectly free from disease?

*L*—Have either parent or any of the brothers or sisters died from phthisis, or is any member of the family now suffering from that disease? If so, please give particulars

*M*—Are there any other circumstances connected with the Candidate with which you think the Managers should be made acquainted?

*I have this ....... day of..... ...... 19... seen and examined . .. ...... and am of opinion that he is in* . ...........health, and that his constitution is† . .... . I therefore‡........ ... recommend the Managers to accept him as a member.*

*Signature of Medical Referee* ..... ... ..........

*Address* .... ........................ ...

* State whether good, indifferent, or bad. † State whether sound or impaired ‡ Fill in "do not" if you consider case not satisfactory.

*** We agree with our correspondent that 2*s.* 6*d.* is not a proper fee for the services demanded of him. Such questions as those marked E or K entail the most complete physical examination of the patient. Four times the fee offered might well be paid for the physical examination and a similar sum for the written report, and then the Surrey Reformed Benefit Society would have been served at a cheap rate.—ED. L.

Quarter Page, £1 10s. Half a Page, £2 15s. An Entire Page, £5 5s.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION (11, Chandos-street, Cavendish-square, W.) —4 P.M. Cases will be shown by Mr. M. Collier, Dr. McCall, and the President. 5 P.M. Discussion on the Diagnosis and Treatment of Various Forms of Nerve Deafness (opened by Dr. D. Grant and continued by Dr. G. MacDonald, Dr. B. Baron, and others) .7.30 P.M. Annual Dinner at the Cafe Royal.

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY (10th).**—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart: Organs of Respiration.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. J. J Pringle: Clinique. (Skin.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr Saunders: Therapeutics

**TUESDAY (11th).**—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. G. F. Still· Some Abnormal Psychical Conditions in Children (Goulstonian Lecture)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Ewart. Clinique. (Medical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Ball. Diseases of the Tonsils.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury) —3.30 P.M. Mr. Gunn: Visual Fields in Diagnosis.

**WEDNESDAY (12th).**—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C. Stewart Organs of Respiration.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. E. W Roughton: Clinique. (Surgical.)

POST GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr Beddard: Some Functional Disorders.

**THURSDAY (13th).**—ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. F. T. Roberts The Comprehensive Study of Thoracic Phthisis. (Lumleian Lectures)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr. J. Hutchinson, jun: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Davis: Medical Anatomy and Physical Diagnosis.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond street, W.C.).—4 P.M. Mr. S. Colyer: Oral Sepsis in Children.

CHARING CROSS HOSPITAL —4 P.M. Mr. Gibbs: Surgical Cases (Post-Graduate Course.)

**FRIDAY (14th).**—ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 P.M. Prof. C Stewart Organs of Respiration.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr R. Lake Clinique. (Ear.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M. Dr. Shuter: Treatment of a few Effects from Anæsthetics.

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1901, which was completed with the issue of Dec. 28th, and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### *TO SUBSCRIBERS.*

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C, are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c, should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | | | TO THE COLONIES AND ABROAD. | | | |
|---|---|---|---|---|---|---|---|
| One Year ... ... ... | £1 | 12 | 6 | One Year ... ... ... | £1 | 14 | 8 |
| Six Months . ... ... | 0 | 16 | 3 | Six Months ... ... ... | 0 | 17 | 4 |
| Three Months ... ... | 0 | 8 | 2 | Three Months ... ... | 0 | 8 | 8 |

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND

towards the heart, much faster and further than the changes in the vessel wall, and the clot may thus spread as far as the aorta. 4. The earliest effect of this diseased artery is pain, then follow other evidences of local ischæmia and these may pass on to gangrene These effects vary with the extent of the vascular obstruction and the efficiency of nature's means of compensation. 5. The disease may be very chronic, slowly progressing for years, or it may run a much more rapid course Having reached a certain point arrest may occur and the symptoms may gradually pass away as the unaffected vessels become more and more efficient substitutes for those that have been occluded. 6. The disease arrested for a time may afterwards recur in the vessels of the same limb or elsewhere, and it may attack more than one vascular area simultaneously. 7. The vascular changes are not always limited to the arteries and endophlebitis may precede or accompany the endarteritis and the venous obstruction then modifies the effects produced on the tissues.

But I think we shall best appreciate the characters of the affection if I describe cases that I have seen and I will take first of all one that I think is a fairly typical case; I will then narrate others to illustrate, as far as my experience permits me, the salient features which are met with, and I will conclude by drawing attention to some of the points not included in the summary just given.

CASE 1.—A man, a carpenter by trade, was admitted into Middlesex Hospital under my care on July 2nd, 1895. He was then 56 years of age, a stout man, looking rather older than his years. He said that he had enjoyed good health up to October, 1894, when, he knew not why, the left internal saphena vein became swollen, inflamed, and painful from the ankle to the groin. For this he rested in bed and the swelling gradually subsided. The following month (November) the left foot became red and "inflamed," and he was treated for some time for gout. The pain was great and in spite of treatment continued all through the winter, and in March, 1895, the foot was noticed to be shrivelling and turning black. The gangrene gradually extended until it involved all the toes. Throughout his illness the pain had been very great and he had been obliged to keep his bed When admitted to hospital the toes of his left foot were black and shrivelled, blue-black gangrene extended on the foot as far as the mid-tarsal joint, and the skin of the rest of the foot up to the front of the ankle was dry and brownish There was considerable œdema of the leg and the skin was very sensitive; it was colder than the opposite leg and the skin was mottled and rather livid in hue The left femoral, popliteal, and tibial arteries were pulseless and could be felt as firm cords. The arteries elsewhere in the body could be plainly felt pulsating; they were neither rigid, tortuous, nor uneven: they did not show any signs of atheroma or degeneration. There was no arcus senilis; the temporal pulse was not visible. The pulse-rate was 136; it was rather uneven and compressible. The area of the cardiac dulness was diminished, the first sound was short, and the second sound was indistinct; there was no bruit. The man was pale, bald, with grey beard, with a good deal of soft subcutaneous fat; the abdomen was full and fat; the liver was not enlarged. The urine was acid, with a specific gravity of 1018, and it was free from sugar and albumin The man was restless with a rather noisy delirium, but was evidently in great pain. The temperature varied between 100° and 101° F There was no history or evidence of syphilis On the lower part of the right leg was a pigmented scar of an ulcer. I amputated the limb at the knee-joint. There was no bleeding from the popliteal artery when the tourniquet was removed and the end of the vessel could be plainly seen securely plugged by soft solid vascular tissue. There was slight oozing of blood from vessels in the sheath of the artery, showing a very vascular condition of that sheath; only five ligatures were needed for the whole stump. Immediately after the operation the patient lost his delirium and his pain, he became quite quiet, and his general health rapidly improved. The stump healed well and the temperature fell to normal on July 9th, and on the 24th he went to a convalescent home at Swanley. (Owing to an accident the amputated member was not dissected.) For two years this man continued well and got about freely. But during the winter of 1897–98 he came to me at the hospital several times complaining of severe pain in the right foot and leg and a sense of coldness and numbness—these pains were much worse when the weather was very cold or if the part was not warmly covered up I found the foot and leg as high as the knee cold and mottled in colour with very sluggish circulation, and I could not detect any pulsation in either the tibial or the popliteal artery. I advised him to rest the limb and to keep it very warm. It was evident that the disease had now affected the arteries of the right foot and leg. On his last visit in the early summer of 1898 he was rather better. But he was suddenly readmitted to the hospital on Oct. 21st, 1898, in a very grave condition He was incoherent, unable to answer questions, restless, and complained of pain in his foot and leg. His tongue was thickly coated with a white f and he seemed to be very thirsty. His friends stated tha his foot had become cold and blue on the 19th and tha after that he had become rapidly more ill. I found th right foot and lower third of the leg very cold, mottled blue and white, slightly swelled, and the circulation, although nowhere arrested, was yet very sluggish. There was no pulse in the tibial, popliteal, or femoral arteries; they were all, when felt, firm cords. The arteries of the arms, on the other hand, were soft and not tortuous. The pulse was rapid, regular, and compressible. The urine was pale, of specific gravity 1005, acid, free from sugar, with a slight cloud of albumin on boiling. The temperature ranged between 99° and 100° F. I kept the limb as warm as I could with thick cotton wrappings, outside which were placed hot bottles, and tried to relieve his pain with morphia. But he got worse. On the 24th I could not demonstrate any circulation in the foot; in the lower third of the leg it was very languid, but the upper half of the leg was warmer and the circulation was fairly active. The superficial veins were not thrombosed. His temperature was higher (101°), he was less conscious, and sometimes passed his urine in the bed. Remembering his rapid improvement after the former amputation I decided to remov the limb at the time and did it on the 24th. He slept wel after the operation and woke up quieter and more rational. The next afternoon, however, he became more restless; his temperature rose; on the 26th it reached 103·8°, his pulse was counted at 156, and just before midnight on the 26th he died.

On dissecting the leg we found the popliteal artery blocked by a firm organising clot. The posterior tibial artery w quite small, occluded in its entire length by a soft colourle clot; the wall of the vessel was considerably thickene especially at the posterior part of its circumference. Th anterior tibial artery was small, with thickened walls, bu had still a narrow lumen. The arteries were very firmly matted to their companion veins and were separated only with great difficulty. The post-mortem examination was made by Dr. A. F. Voelcker who recorded that the heart was dilated, flabby, with ante-mortem clots in both ventricles and in the right auricular appendix. The aorta in the thorax showed very trifling disease and there was no atheromatous ulceration. The carotid and subclavian arteries and the jugular, innominate, and superior caval veins were norma The femoral and iliac vessels were blocked with clot, th lumen of the vessels was only a little diminished, and except for some calcareous patches the walls did not show any marked change. The clot extended up the abdominal aorta as high as the origin of the renal branches and here ended in a conical tip. The left kidney showed one infarct; the right had many.

This case is fairly typical of the affection called obliterative arteritis. I would call attention specially to the insidious onset, slow progress, the severe pain coming on as the firs symptom and lasting throughout—pain that was worse in cold weather or when from any cause the affected part was exposed to cooling Then the signs of local ischæmia with loss of pulse in the arteries and their conversion into solid cords, passing at length into gangrene of the most distant sections of the member,—all t associated with a healthy condition of the arteries gene as shown by their softness, smoothness, and absence of volution and locomotor pulse at the elbow and temple, instance The symptoms may vary in intensity a little time to time, but there is never the marked periodicit intermission of symptoms that characterise Rayna disease. The obstruction to the circulation, whatever it is organic and permanent from the first, and capable of rel only by the agency of anastomosing and alternative arteri The essence of Raynaud's disease is vascular spasm, variab and temporary, and only causing permanent changes gangrene—when prolonged spasm is followed by thrombos Hæmoglobinuria which often occurs in Raynaud's disease never present in obliterative arteritis. The case which I hav

## LECTURE II [1]

*Delivered on March 3rd*

### ON OBLITERATIVE ARTERITIS

MR PRESIDENT AND GENTLEMEN,—I have chosen Obliterative Arteritis as the subject of this lecture partly because of the obscurity in which its origin and causes are wrapped and partly because many of us are not so familiar with the main features of the disease as its frequency and gravity demand It has barely found its way into our text books, and it is still regarded as a very rare affection, and yet it cannot be so when from my own experience I can cite nine cases The first important paper on the subject was written by Friedlander[2] in 1876, and was followed three years later by an article by Winiwater[3] giving a very careful description of the vessels in a case that had been under Billroth's care Isolated cases were previously described by Jaesche[4] in 1865 and by Burow[5] in 1857 But it is undoubtedly to Friedlander that the credit belongs of recognising the condition and of working out its pathology Since his paper was published many examples of the disease have been described, but very little further light has been thrown upon it In 1884 I[6] recorded a well marked case affecting the vessels of the upper limb in a man 19 years of age and at the same meeting of the Clinical Society the late Dr W B Hadden[7] recorded another case of the disease in the hand and forearm of a woman aged 35 years The following year Mr W J Walsham[8] reported to the same society a case of "acute obliterative arteritis" in the arm of a man aged 52 years, but there is some room for doubt whether it belonged to the same category or to that of acute spreading arterial thrombosis In 1891 I[9] read a paper on a case in which the disease caused symmetrical gangrene in the feet of a man aged 43 years In 1894 Saverain[10] recorded a case which began with an attack of phlebitis after which there were persistent pain and lameness in the left foot, in a year the toes became gangrenous and the leg was amputated Saverain found endarteritis in the anterior tibial artery and endophlebitis in the accompanying veins In 1896 Mr Hutchinson[11] described four typical cases and called attention to the importance of examining the state of the artery in the thigh in all cases of gangrene of the foot In 1897 a Russian surgeon Wwedensky[12] wrote of the disease as peculiar to Russia and occurring in men between 19 and 60 years In 1898 Mr W G Spencer[13] recorded a very remarkable case in which the arteries in both legs and in one arm were simultaneously affected Amputation through the middle of the left thigh was necessary, and Mr Spencer gave an admirable account of the condition of the vessels in the amputated limb About the same time Dr W A Hollis[14] discussed the affection from its pathological side and in 1900 Sternberg[15] in a long article described several cases of spontaneous gangrene in young people The arteries of the limbs examined showed total obliteration of their lumen with very vascular connective tissue internal to the elastic lamina, and Gibert[16] described a case of symmetrical gangrene of the feet from arteritis

Before narrating any of the cases of this disease that I have seen I wish to make one or two preliminary observations And first of all I would remind you of the paramount part that the inner coat takes in all active physiological and pathological processes in arteries The prime office of an artery is to maintain a patent channel for the flow of blood and this depends upon the integrity of the tunica intima The physiological obliteration of obsolete vessels, such as the ductus arteriosus and the umbilical vessels, and the narrowing of vessels in stumps are effected almost entirely by proliferation of cells of the intima—the middle and outer coats take no active share in the process Similarly the repair of a wounded artery or of a ligatured vessel is dependent upon the activity of the cells of the intima If an artery is temporarily compressed or bruised or its outer surface is cauterised the changes produced are witnessed in the intima If from any cause a thrombus forms in a vessel it is the inner tunic of the vessel which reacts to its presence, and if the blood circulating through a vessel is irritating or the tension high it is the same coat that suffers The only primary change in the middle coat is one of simple degeneration—calcification—and we know nothing at all of any primary change originating in the tunica adventitia The tunica intima is in fact, the essential part of an artery, it is present throughout the entire system and is equally important everywhere The muscular coat is added as a vaso motor mechanism and the outer coat is an added strength to the artery, but both of these are subsidiary—there are vessels without the one or the other—but without the tunica intima there can be no vessel at all Disease not only occurs in the inner coat of an artery more frequently than in either of the others—e g, atheroma—but there its effects are most serious For when the inner coat is very gravely affected its function is interfered with and the lumen of the vessel is occluded and this occlusion is brought about in one or both of two ways In the first place any hyperplasia of the endothelium or sub endothelial tissue causes a bulging into the lumen of the vessel the elastic lamina on the outer surface is a very resistant structure and as it were shuts in the cells and soft tissues and prevents their bulging out or passing into the muscular and fibrous tunics The direction of growth is towards the centre of the vessel But disease of the inner coat especially when the endothelium is involved very quickly leads to thrombosis, which in small vessels at once obliterates the lumen and except in rare cases the clot soon becomes organised into vascular cellular tissue

Of these two agents in the obliteration of arteries—new growth and thrombus—it must be borne in mind that while thrombosis may be and often is a very rapid process the growth of the inner coat to such an extent as to fill the lumen of a vessel is always a slower process and slow in direct proportion to the size of the vessel We must also bear in mind that a clot in an artery or a vein has a tendency to extend and we often find it extend very rapidly, but the primary inflammatory growths of the intima appear to be much slower in their progress along an artery And, lastly, another difference between these two occluding agents seems to be this—that a blood clot may be absorbed and disappear and the vessel which it has closed opened out again but a like opening out of a vessel once closed with sub endothelial growth so far as we know, never occurs

These considerations in my opinion make it very doubtful whether obliterative arteritis is a specific disease to be sharply differentiated, I would rather regard it as a pathological effect of many causes, and I would not therefore separate it from the syphilitic disease of small arteries described by Heubner and others The chief features of obliterative arteritis are these —1 The disease originates in the subendothelial layers of the tunica intima of the smaller arteries In its early stages it is marked by a small-cell infiltration which later organises into a loose and vascular connective tissue 2. This growth narrows the lumen of the vessel and may entirely obliterate it, more often however thrombosis occurs and the organisation of the clot completes the permanent occlusion of the artery 3. The disease beginning in the smaller arteries tends to spread in a centripetal direction and may reach even the larger arteries The thrombosis it excites also often extends rapidly and far towards the heart, much faster and further than the changes in the vessel wall, and the clot may thus spread as far as the aorta. 4. The earliest effect of this diseased artery is pain, then follow other evidences of local ischæmia and these may pass on to gangrene These effects vary with the extent of the vascular obstruction and the efficiency of nature's means of compensation. 5. The disease may be very chronic, slowly progressing for years, or it may run a much more rapid course. Having reached a certain point arrest may occur and the symptoms may gradually pass away as the unaffected vessels become more and more efficient substitutes for those that have been occluded. 6. The disease arrested for a time may afterwards recur in the vessels of the same limb or elsewhere, and it may attack more than one vascular area simultaneously. 7. The vascular changes are not always limited to the arteries and endophlebitis may precede or accompany the endarteritis and the venous obstruction then modifies the effects produced on the tissues.

But I think we shall best appreciate the characters of the affection if I describe cases that I have seen and I will take first of all one that I think is a fairly typical case; I will then narrate others to illustrate, as far as my experience permits me, the salient features which are met with, and I will conclude by drawing attention to some of the points not included in the summary just given.

CASE 1.—A man, a carpenter by trade, was admitted into Middlesex Hospital under my care on July 2nd, 1895. He was then 56 years of age, a stout man, looking rather older than his years. He said that he had enjoyed good health up to October, 1894, when, he knew not why, the left internal saphena vein became swollen, inflamed, and painful from the ankle to the groin. For this he rested in bed and the swelling gradually subsided. The following month (November) the left foot became red and "inflamed," and he was treated for some time for gout. The pain was great and in spite of treatment continued all through the winter, and in March, 1895, the foot was noticed to be shrivelling and turning black. The gangrene gradually extended until it involved all the toes. Throughout his illness the pain had been very great and he had been obliged to keep his bed. When admitted to hospital the toes of his left foot were black and shrivelled, blue-black gangrene extended on the foot as far as the mid-tarsal joint, and the skin of the rest of the foot up to the front of the ankle was dry and brownish. There was considerable œdema of the leg and the skin was very sensitive; it was colder than the opposite leg and the skin was mottled and rather livid in hue. The left femoral, popliteal, and tibial arteries were pulseless and could be felt as firm cords. The arteries elsewhere in the body could be plainly felt pulsating; they were neither rigid, tortuous, nor uneven: they did not show any signs of atheroma or degeneration. There was no arcus senilis; the temporal pulse was not visible. The pulse-rate was 136; it was rather uneven and compressible. The area of the cardiac dulness was diminished, the first sound was short, and the second sound was indistinct; there was no bruit. The man was pale, bald, with grey beard, with a good deal of soft subcutaneous fat; the abdomen was full and fat; the liver was not enlarged. The urine was acid, with a specific gravity of 1018, and it was free from sugar and albumin. The man was restless with a rather noisy delirium, but was evidently in great pain. The temperature varied between 100° and 101° F. There was no history or evidence of syphilis. On the lower part of the right leg was a pigmented scar of an ulcer. I amputated the limb at the knee-joint. There was no bleeding from the popliteal artery when the tourniquet was removed and the end of the vessel could be plainly seen securely plugged by soft solid vascular tissue. There was slight oozing of blood from vessels in the sheath of the artery, showing a very vascular condition of that sheath; only five ligatures were needed for the whole stump. Immediately after the operation the patient lost his delirium and his pain, he became quite quiet, and his general health rapidly improved. The stump healed well and the temperature fell to normal on July 9th, and on the 24th he went to a convalescent home at Swanley. (Owing to an accident the amputated member was not dissected.) For two years this man continued well and got about freely. But during the winter of 1897–98 he came to me at the hospital several times complaining of severe pain in the right foot and leg and a sense of coldness and numbness—these pains were much worse when the weather was very cold or if the part was not warmly covered up. I found the foot and leg as high as the knee cold and mottled in colour with very sluggish circulation, and I could not detect any pulsation in either the tibial or the popliteal artery. I advised him to rest the limb and to keep it very warm. It was evident that the disease had now affected the arteries of the right foot and leg. On his last visit in the early summer of 1898 he was rather better. But he was suddenly readmitted to the hospital on Oct. 21st, 1898, in a very grave condition. He was incoherent, unable to answer questions, restless, and complained of pain in his foot and leg. His tongue was thickly coated with a white fur and he seemed to be very thirsty. His friends stated that his foot had become cold and blue on the 19th and that after that he had become rapidly more ill. I found the right foot and lower third of the leg very cold, mottled blue and white, slightly swelled, and the circulation, although nowhere arrested, was yet very sluggish. There was no pulse in the tibial, popliteal, or femoral arteries; they were all, when felt, firm cords. The arteries of the arms, on the other hand, were soft and not tortuous. The pulse was rapid, regular, and compressible. The urine was pale, of specific gravity 1005, acid, free from sugar, with a slight cloud of albumin on boiling. The temperature ranged between 99° and 100° F. I kept the limb as warm as I could with thick cotton wrappings, outside which were placed hot bottles, and tried to relieve his pain with morphia. But he got worse. On the 24th I could not demonstrate any circulation in the foot; in the lower third of the leg it was very languid, but the upper half of the leg was warmer and the circulation was fairly active. The superficial veins were not thrombosed. His temperature was higher (101°), he was less conscious, and sometimes passed his urine in the bed. Remembering his rapid improvement after the former amputation I decided to remove the limb at the time and did it on the 24th. He slept well after the operation and woke up quieter and more rational. The next afternoon, however, he became more restless; his temperature rose; on the 26th it reached 103 8°, his pulse was counted at 156, and just before midnight on the 26th he died.

On dissecting the leg we found the popliteal artery blocked by a firm organising clot. The posterior tibial artery was quite small, occluded in its entire length by a soft colourless clot; the wall of the vessel was considerably thickened, especially at the posterior part of its circumference. The anterior tibial artery was small, with thickened walls, but had still a narrow lumen. The arteries were very firmly matted to their companion veins and were separated only with great difficulty. The post-mortem examination was made by Dr. A. F. Voelcker who recorded that the heart was dilated, flabby, with ante-mortem clots in both ventricles and in the right auricular appendix. The aorta in the thorax showed very trifling disease and there was no atheromatous ulceration. The carotid and subclavian arteries and the jugular, innominate, and superior caval veins were normal. The femoral and iliac vessels were blocked with clot, the lumen of the vessels was only a little diminished, and except for some calcareous patches the walls did not show any marked change. The clot extended up the abdominal aorta as high as the origin of the renal branches and here ended in a conical tip. The left kidney showed one infarct; the right had many.

This case is fairly typical of the affection called obliterative arteritis. I would call attention specially to the insidious onset, slow progress, the severe pain coming on as the first symptom and lasting throughout—pain that was worse in cold weather or when from any cause the affected part was exposed to cooling. Then the signs of local ischæmia with loss of pulse in the arteries and their conversion into solid cords, passing at length into gangrene of the most distant sections of the member,—all th associated with a healthy condition of the arteries genera as shown by their softness, smoothness, and absence of co volution and locomotor pulse at the elbow and temple, instance. The symptoms may vary in intensity a little fro time to time, but there is never the marked periodicity intermission of symptoms that characterise Raynaud disease. The obstruction to the circulation, whatever it is, organic and permanent from the first, and capable of reli only by the agency of anastomosing and alternative arteri The essence of Raynaud's disease is vascular spasm, variab and temporary, and only causing permanent changes— gangrene—when prolonged spasm is followed by thrombos Hæmoglobinuria which often occurs in Raynaud's disease never present in obliterative arteritis. The case which I hav quoted is instructive, too, in the recurrence of the malady in another limb, and this event is so important that I will briefly quote another case in which I have seen it

CASE 2 —A man, aged 60 years, a carpenter, was admitted into Middlesex Hospital under my care on May 12th, 1897 There was no family history of importance His general health had always been good, he had been a temperate man and had not had syphilis, gout, or tubercle He told us that he was subject to chilblains, especially when young, and that he had injured his right leg and foot on two occasions, once, 28 years before we saw him, when the lower part of the leg was "crushed" and it took six months to heal up 18 years later the right great toe was contused, the nail separated and had never grown again He had been laid up for three and a half years when I first saw him The trouble began, he said with a sore formed on the left heel which became black (gangrenous); later the little toe, then the second toe, and afterwards the third toe became gangrenous, part of the second toe had separated spontaneously Four months before admission he noticed a black spot on the great toe Two months later the skin over the dorsum of the foot became blue, and this spread to the leg All this time he had suffered from dull aching pain with sharp twinges in a part before it became black He was a dark-haired, thin, emaciated man He was depressed, haggard looking, and complained of great pain and inability to sleep The left foot and ankle were blue and cold and on the outer side this extended as high as the middle of the leg The three inner toes were mummified, there was a large patch of dry gangrene on the dorsum of the foot, the sole of the foot was purple and cold but not actually gangrenous No pulse was felt in either tibial artery, there was slight pulsation in the popliteal artery There was some matting of tissues over the dorsum of the right foot and the lower fourth of the leg; the skin was thin and atrophied, there was no loss of sensation or of pulsation in the arteries The heart was healthy; the temporal artery was not visible or tortuous there was no locomotion or tortuosity of the brachial artery at the elbow The urine had a specific gravity of 1017 it was free from sugar, and it contained excess of phosphates and a faint trace of albumin The temperature ranged from 100° to 101° F I amputated the left leg at the knee-joint only three arteries were tied—the popliteal, a large branch coming off from it and the internal sural artery, the popliteal artery was thickened with a narrow lumen and would not twist The arteries in the amputated leg were found to be all greatly thickened, the dorsal artery of the foot and the external plantar artery were occluded, the internal plantar was still patent The veins in the sole were thrombosed, those in the leg were pervious The man made a slow convalescence, part of the outer flap sloughed, and the bone had to be shortened But he eventually left the hospital for the convalescent home in August, 1897, free from pain, sleeping well, cheerful, and quite a different man from when he came in

He remained well till March 1899, when he found that the inner side of his great toe was tender and he began to suffer pain in the foot At the end of September a black patch appeared at the root of the great toe and the gangrene spread to the other toes and the dorsum of the foot The pain meantime increased to great severity, described as aching in character, with sharp twinges or paroxysms He was again admitted into the hospital on Nov 29th 1899, having been ill nine months The left stump was sound and well, it was very difficult to detect any pulsation in the femoral artery on that side The right foot was swollen, cold, mottled in colour, and the toes were gangrenous He complained of intense pain in the foot and was evidently in great suffering There was no pulse to be felt in any artery below the femoral The radial artery was not hardened or tortuous and there was no evidence of disease in other arteries The urine was of specific gravity 1020, free from sugar, and contained a trace of albumin On Dec 2nd I amputated through the condyles of the femur by Lister's method The popliteal and two or three small arteries were tied, the wall of the popliteal artery was much thickened Convalescence was again slow but he went to Clacton with the stump healed on Jan 11th and returned on Feb 6th, having gained 13½ pounds in the four weeks I have seen this man occasionally since The left stump has given him no trouble, but on his last visit to me the right thigh was very painful, it was cold, rather blotchy and blue, and I could not feel any pulse in the femoral artery I advised him to keep it very warm.

The liability for the disease to attack both lower limbs was illustrated by a case that I reported to the Clinical Society and which will be found recorded in vol xxiv of that society's Transactions

CASE 3 —The patient was a man, aged 43 years, a draper's traveller While an inmate of an asylum for acute mania supervening upon an attack of influenza he was seized with severe pain in his feet and legs They were noticed to become cold and blue and in a few days gangrenous When admitted to the Middlesex Hospital there was gangrene on each side as high as the bases of the malleoli with mummification of the toes and œdema of the legs Pulsation could not be felt in the popliteal or tibial arteries, the heart sounds were normal, the pulse was 88, and the brachial arteries were not obviously diseased The urine was acid, free from albumin and sugar I amputated the legs at the knee-joints and the patient made a good recovery I have heard nothing of him since The popliteal arteries, where divided, were filled with organising clot, and the wall of the vein was thickened The arteries and some of the veins in the leg showed marked thickening of the interior coat with, in places, occlusion of the lumen by coagulum, there was no calcareous degeneration

These three cases will suffice to illustrate the tendency of the disease to attack the vessels of more than one limb, either concurrently or successively Mr Spencer has recorded a very interesting case in which three limbs, the right arm and both legs, were simultaneously affected.

Let me now relate some cases from which I think we may learn something of the etiology of this affection The first of them is that of a woman who developed symptoms of erythromelalgia after an attack of influenza and then shortly afterwards showed signs of local ischæmia in the same limb caused by arterial obliteration

CASE 4 —The patient was a woman, aged 65 years, seen in consultation with Dr Ker and Dr Aldren Turner I am indebted to Dr Turner for the notes of the earlier history of this patient This patient had enjoyed good health until the early part of 1898 when she had an attack of influenza She made a good recovery and remained well through the summer In October, 1898, she experienced pain in her right foot without any loss of power This continued more or less all through that winter and the following spring, and in August, 1899, she consulted Dr Aldren Turner He found marked tenderness over most of the nerves of the upper and lower limbs, she complained of pain in the right foot, and over the toes there was marked superficial pain, with redness and increased heat She could scarcely bear to place the foot on the ground so great was the pain produced There was no paralysis She was thin and all the tissues were flabby Dr Turner ordered galvanism When next seen in September there was marked improvement in the foot—apparently as the result of the galvanism General massage and the recumbent position were then ordered, and bromide of potassium, salicylate of soda, and phenacetin were prescribed On Oct 6th Dr Turner received a letter from Dr Ker, stating that there had not been any improvement lately and the treatment seemed to have lost its beneficial effect But very soon after that the patient appeared to get quite well, she went about freely, walking was easy to her, and she went on a visit into the country On Jan 14th 1900, Dr Turner visited her in the country and learnt that she had continued well until the onset of very cold frosty weather about 14 days before Christmas when she had great pain and a burning sensation in the right foot, followed shortly after by signs of local asphyxia in the toes—chiefly the second toe At his visit he found all the toes of the right foot blue, there was a large blue patch over the right heel, and another over the dorsum of the foot The foot felt moderately cold to his hand, but subjectively was said to be very cold The toes were very tender, there was no anæsthesia The pain in the foot was intense at times, chiefly at night. There was no pulse in the posterior tibial artery, the radial pulse was of good volume and there was no sign of marked atheroma; and no affection of the nose or ears was present. The patient complained of slight pains in the left toes, where there was some doubtful redness, and also of slight numbness in the fingers. The pain continued very severe, the condition of the foot became worse, and I was asked to see the patient on Jan. 24th There was then gangrene of the toes and dorsum of the foot and the heel I could not detect pulsation in any of the arteries of the right lower limb below the middle of the thigh; the arteries could be felt as firm cords Pulsation could be plainly felt in all the arteries of the left thigh and leg. The urine contained lithates, but was free from sugar and albumin. The radial, brachial, and temporal arteries did not show atheromatous change. The patient was thin, much worn by her suffering, and her appetite was failing. She got very little sleep. The heart and lungs and the liver were healthy. The right kidney was moveable. There was no evidence of syphilis or of alcoholism. We advised amputation and next day I removed the limb just above the knee-joint. The popliteal artery was a solid cord and did not require a ligature. She made a good recovery from the operation, the stump healed well, and the pain was at once greatly relieved and the patient's general condition correspondingly improved. I was, however, asked to see this patient in March—two months after the amputation—and I found that she was then suffering from severe pain in the thigh. This was swollen quite considerably and the skin was marked with blotches of blue and red; the surface was cold. The pain in the thigh was described as very severe. I could not feel any pulse in the femoral or external iliac arteries. The arteries on the left side pulsated normally. I advised that the limb should be kept raised, very warmly swathed, and gently massaged twice a day. At the same time I gave a serious prognosis, as I feared that the disease might extend to some visceral artery. I did not see the patient again, but Dr. Ker has informed me that the pain, swelling, and discolouration of the thigh disappeared, and the patient seemed to get "quite well" so far as the arterial disease was concerned. She died in 1901 from some chest affection—not from anything connected with the old trouble. She was not then under Dr. Ker's care and I have not been able to obtain more precise information. The arteries in the amputated limb showed the usual changes. The popliteal, tibial, and peroneal vessels, as far as they could be traced, were converted into solid cords with greatly thickened walls. The tunica intima was much thickened and the narrowed lumen was occluded with organising thrombus

This case is specially interesting because of the history of the onset of the affection—unique in my experience and reading. When Dr. Aldren Turner first saw this patient she presented the symptoms of erythromelalgia—that is to say, neuralgic pains with signs of dilatation of the arteries and increased vascularity of the tissues. There was local heat and the pain was greatly increased by putting the foot to the ground and by warmth. This was the state of things in the summer of 1899, and these symptoms passed off and the patient appeared to be quite well in the autumn. But with the onset of wintry weather the picture was strangely altered; the local heat and flushing were changed into coldness and sluggish circulation which gradually culminated in gangrene. Erythromelalgia is a rare affection and but little is known about it. In his excellent article in Clifford Allbutt's "System of Medicine" Sir Thomas Barlow sums up the evidence for and against the various views of its pathology that have been advanced, and shows that the balance of evidence is in favour of the view of its consisting in a dilatation of the arteries caused by paresis or inhibition of the vaso-motor nerves Whether this be a primary or a sequential phenomenon the dilated arteries are the most important feature of the disease, and Sir Thomas Barlow very pertinently remarks that the arterial dilatation might excite changes in the intima and lead to thickening of the arteries and narrowing of their tissues; he refers to Thoma's experiments to show that increased arterial tension, if kept up, leads to proliferation of the intima The case I have related shows us this very sequence. It is also of interest as an illustration of the tendency of the disease to spread upwards even after amputation well above the gangrenous area and of the smaller gravity of the disease in the thigh than in the foot and the leg.

The next case illustrates another cause of the same condition.

CASE 5—The patient was a woman, aged 45 years, seen in consultation with Dr S Blake Jolly. For many years she had suffered from very severe menorrhagia which had kept her in a state of extreme anæmia. For years she had taken alcohol in excess, chiefly in the form of spirit. She was constantly needing medical attention, either for the hæmorrhage, or the anæmia, or the effects of special alcoholic excess Ten days before I saw her Dr. Jolly was called in and found her in great pain in her left foot with paroxysms of very severe agony; the foot was colder than the other, pale, mottled in colour, with sluggish circulation. The severe pain continued in spite of the application of local heat, and injections of morphia had to be given. I saw the patient on March 6th, 1900; she was very stout and flabby with a very fat abdomen, her skin was white and her mucous membranes were very pale, and she looked very unhealthy. The toes of the left foot were gangrenous, blue-red in colour, not altered in size, and the gangrene extended for about an inch on to the dorsum of the foot and a little further on to the sole. The rest of the foot was cold, mottled blue and white in colour, but the skin retained its sensitiveness as far down as the edge of the gangrene. I could not feel a pulse in the popliteal artery or either of the tibial arteries; there was pulsation in the femoral artery and in the tibial arteries of the right side. There was no evidence of general atheroma of the arteries. The brachial artery was not tortuous or hard. There was no valvular disease of the heart. The urine was free from sugar, but it contained a very slight trace of albumin. This patient was in very severe pain in the foot and leg. I recommended amputation and next day removed the limb above the knee-joint. This patient made an excellent recovery. I heard of her quite recently from Dr. Jolly and he told me that her stump had remained well, so had her left foot and leg, and that she had continued the abstinence from alcohol which we enforced during the healing of the wound and with very great benefit to herself. I think the *causa causans* in this case was the alcoholism—the irritating effect of the alcohol circulating in her blood. The case illustrates also what we so often see—the great benefit which alcoholic patients derive from breaking off the habit and excluding alcohol altogether from their dietary even when organic change such as obliterative arteritis has taken place. If this patient will continue her abstinence from alcohol I am very hopeful that she will have no return of the disease. She has been free from it for two years already.

In the following case the condition probably resulted from syphilis. This patient was in the Middlesex Hospital under the care of Dr. W. Pasteur, and I am indebted to him for an opportunity of examining the man and for permission to use the notes of the case.

CASE 6.—A man, aged 48 years, a gardener, was admitted into Middlesex Hospital on Jan. 3rd, 1898 He had had good health up to the time of this illness and we failed to elicit from him any history of syphilis or of injury. He said that for three and a half years he had suffered from redness and a burning and stinging pain in the left great toe at night, so severe as to prevent sleep. This pain sometimes came on during the day. Similar symptoms came on in the right foot about six weeks after he noticed them in the left. The feet were at times quite white, at others blue, and he noticed then that when he pressed the colour out with his finger it returned very slowly. The great toes suffered most, the other toes to a less extent He had not noticed any numbness or loss of sensation. Six months before he came under observation he observed mottled redness of the soles of the feet, and a month before admission he saw a blister on the tip of the right great toe; this gradually extended under the nail and beneath it a black eschar was seen. This change was accompanied by most excruciating pain. He was a man of spare build and nervous habit; his pulse was 72, weak and compressible; the heart sounds were healthy. The urine was acid, 1020, and there was no albumin or sugar. The temperature ranged between 97·6° and 99° F. The skin of each foot, especially on the sole, was much mottled and generally reddened; on the end of the right great toe was a patch of black gangrenous skin. He suffered great pain, and even hypodermic injections of morphia failed to give him more than two hours' sleep at a time. There was no pulse in either posterior tibial artery or in the left popliteal and femoral; that in the right femoral artery was quite distinct The gangrenous patch on the toe extended a little, the slough slowly separated, and the ulcerated surface still more slowly healed. He was sent to Clacton on Feb. 27th in good general health, nearly free from pain, but still showing blotchy discolouration and sluggish circulation in both feet. The man returned to hospital on April 13th, 1898, on account of increasing pain in the left foot. The right femoral pulse was only just perceptible, the left could not be felt. and the artery was represented by a hard cord in Scarpa's triangle. No arterial pulse was felt in either limb below the femoral artery. The toes of the left foot were of dark blue-black colour and "somewhat swollen." There was very distinct "marbling" of the foot with purple and red and paler areas. The lividity of the toes increased, blisters formed and burst, and exposed foul, discharging surfaces, and slowly in quoted is instructive, too, in the recurrence of the malady in another limb, and this event is so important that I will briefly quote another case in which I have seen it.

CASE 2.—A man, aged 60 years, a carpenter, was admitted into Middlesex Hospital under my care on May 12th, 1897. There was no family history of importance. His general alth had always been good; he had been a temperate man d had not had syphilis, gout, or tubercle. He told us that e was subject to chilblains, especially when young, and at he had injured his right leg and foot on two occasions, nce, 28 years before we saw him, when the lower part of the eg was "crushed" and it took six months to heal up. 18 years later the right great toe was contused; the nail separated and had never grown again. He had been laid up for three and a half years when I first saw him. The trouble began, he said, with a sore formed on the left heel which became black (gangrenous); later the little toe, then the second toe, and afterwards the third toe became gangrenous; part of the second toe had separated spontaneously. Four months before admission he noticed a black spot on the great toe. Two months later the skin over the dorsum of the foot became blue, and this spread to the leg. All this time he had suffered from dull aching pain with sharp twinges in a part before it became black. He was a dark-haired, thin, emaciated man. He was depressed, haggard-looking, and complained of great pain and inability to sleep. The left foot and ankle were blue and cold and on the outer side this extended as high as the middle of the leg. The three inner toes were mummified; there was a large patch of dry gangrene on the dorsum of the foot; the sole of the foot was purple and cold but not ctually gangrenous. No pulse was felt in either tibial rtery; there was slight pulsation in the popliteal artery. There was some matting of tissues over the dorsum of the right foot and the lower fourth of the leg; the skin was thin and atrophied; there was no loss of sensation or of pulsation in the arteries. The heart was healthy; the temporal artery was not visible or tortuous, there was no locomotion or tortuosity of the brachial artery at the elbow. The urine had a specific gravity of 1017, it was free from sugar, and it contained excess of phosphates and a faint trace of albumin. The temperature ranged from 100° to 101° F. I amputated the left leg at the knee-joint; only three arteries were tied—the popliteal, a large branch coming off from it and the internal sural artery; the popliteal artery was thickened with a narrow lumen and would not twist. The arteries in the amputated leg were found to be all greatly thickened; the dorsal artery of the foot and the external plantar artery were occluded, the internal plantar was still patent. The veins in the sole were thrombosed, those in the leg were pervious. The man made a slow convalescence, part of the outer flap sloughed, and the bone had to be shortened. But he eventually left the hospital for the convalescent home in August, 1897, free from pain, sleeping well, cheerful, and quite a different man from when he came in.

He remained well till March, 1899, when he found that the inner side of his great toe was tender and he began to suffer pain in the foot. At the end of September a black patch appeared at the root of the great toe and the gangrene spread to the other toes and the dorsum of the foot. The pain meantime increased to great severity, described as aching in character, with sharp twinges or paroxysms. He was again admitted into the hospital on Nov. 29th, 1899, having been ill nine months. The left stump was sound and well; it was very difficult to detect any pulsation in the femoral artery on that side. The right foot was swollen, cold, mottled in colour, and the toes were gangrenous. He complained of intense pain in the foot and was evidently in great suffering. There was no pulse to be felt in any artery below the femoral. The radial artery was not hardened or tortuous and there was no evidence of disease in other arteries. The urine was of specific gravity 1020, free from sugar, and contained a trace of albumin. On Dec. 2nd I amputated through the condyles of the femur by Lister's method. The popliteal and two or three small arteries were tied; the wall of the popliteal artery was much thickened. Convalescence was again slow, but he went to Clacton with the stump healed on Jan 11th and returned on Feb. 6th, having gained 13½ pounds in the four weeks. I have seen this man occasionally since. The left stump has given him no trouble, but on his last visit to me the right thigh was very painful; it was cold, rather blotchy and blue, and I could not feel any pulse in the femoral artery. I advised him to keep it very warm.

The liability for the disease to attack both lower limbs was illustrated by a case that I reported to the Clinical Society, and which will be found recorded in vol. xxiv. of that society's Transactions.

CASE 3.—The patient was a man, aged 43 years, a draper's traveller. While an inmate of an asylum for acute mania supervening upon an attack of influenza he was seized with severe pain in his feet and legs. They were noticed to become cold and blue and in a few days gangrenous. When admitted to the Middlesex Hospital there was gangrene on each side as high as the bases of the malleoli with mummification of the toes and œdema of the legs. Pulsation could not be felt in the popliteal or tibial arteries, the heart sounds were normal, the pulse was 88, and the brachial arteries were not obviously diseased. The urine was acid, free from albumin and sugar. I amputated the legs at the knee-joints and the patient made a good recovery. I have heard nothing of him since. The popliteal arteries, where divided, were filled with organising clot, and the wall of the vein was thickened. The arteries and some of the veins in the leg showed marked thickening of the interior coat with, in places, occlusion of the lumen by coagulum; there was no calcareous degeneration.

These three cases will suffice to illustrate the tendency of the disease to attack the vessels of more than one limb, either concurrently or successively. Mr. Spencer has recorded a very interesting case in which three limbs, the right arm and both legs, were simultaneously affected.

Let me now relate some cases from which I think we may learn something of the etiology of this affection. The first of them is that of a woman who developed symptoms of erythromelalgia after an attack of influenza and then shortly afterwards showed signs of local ischæmia in the same limb caused by arterial obliteration.

CASE 4.—The patient was a woman, aged 65 years, seen in consultation with Dr. Ker and Dr. Aldren Turner. I am indebted to Dr. Turner for the notes of the earlier history of this patient. This patient had enjoyed good health until the early part of 1898, when she had an attack of influenza. She made a good recovery and remained well through the summer. In October, 1898, she experienced pain in her right foot without any loss of power. This continued more or less all through that winter and the following spring, and in August, 1899, she consulted Dr. Aldren Turner. He found marked tenderness over most of the nerves of the upper and lower limbs; she complained of pain in the right foot, and over the toes there was marked superficial pain, with redness and increased heat. She could scarcely bear to place the foot on the ground so great was the pain produced. There was no paralysis. She was thin and all the tissues were flabby. Dr Turner ordered galvanism. When next seen in September there was marked improvement in the foot—apparently as the result of the galvanism. General massage and the recumbent position were then ordered, and bromide of potassium, salicylate of soda, and phenacetin were prescribed. On Oct. 6th Dr Turner received a letter from Dr. Ker, stating that there had not been any improvement lately and the treatment seemed to have lost its beneficial effect. But very soon after that the patient appeared to get quite well, she went about freely, walking was easy to her, and she went on a visit into the country. On Jan 14th, 1900, Dr. Turner visited her in the country and learnt that she had continued well until the onset of very cold frosty weather about 14 days before Christmas, when she had great pain and a burning sensation in the right foot, followed shortly after by signs of local asphyxia in the toes—chiefly the second toe. At his visit he found all the toes of the right foot blue, there was a large blue patch over the right heel, and another over the dorsum of the foot. The foot felt moderately cold to his hand, but subjectively was said to be very cold. The toes were very tender; there was no anæsthesia. The pain in the foot was intense at times, chiefly at night. There was no pulse in the posterior tibial artery; the radial pulse was of good volume and there was no sign of marked atheroma; and no affection of the nose or ears was present. The patient complained of slight pains in the left toes, where there was some doubtful redness, and also of slight numbness in the fingers. The pain continued very severe, the condition of the foot became worse, and I was asked to see the patient on Jan. 24th. There was then gangrene of the toes and dorsum of the foot and the heel. I could not detect pulsation in any of the arteries of the right lower limb below the middle of the thigh; the arteries could be felt as firm cords. Pulsation could be

*Age.*—My youngest patient was 19 years of age and my oldest was 60 years of age. It seems to be a disease of adult life, not occurring in infancy or in old age. Dr. Bryant and Dr. W. Hale White have recorded a remarkable case in the fifty-fifth volume of the Guy's Hospital Reports of an infant, six months old, who had gangrene of the toes and distal half of the foot. The child was greatly emaciated and died. There was widespread arterial disease, the inner coat was greatly thickened and there was calcification of the deep layers of the intima and of the media, so that the artery cracked when bent and felt gritty. I hesitate to include this case in the same category as those which we are considering. It seems to stand out as almost unique—possibly it is of the same nature as one recorded by Durante.[17]

*Etiology.*—Various views of the causes of this form of endarteritis have been advanced. Friedlander attributed it to the influence of injury and external cold. Wwedensky believes that there is a neuritis associated with, and possibly antecedent to, the arteritis. Sternberg attributed it to the effect of various injuries upon a weak and depressed vascular system. Hollis suggests that by the repeated impact of foreign particles against the sides of a small artery a state of "irritation" or "molecular unrest" is established within certain endothelial cells. This unrest manifests itself physiologically by rousing the little central mass of nuclear protoplasm of the cell from a dormant condition to activity. We really know so little of the ultimate causes and processes of disease that it is difficult to accept or to reject such theories as these Of all known causes syphilis is perhaps the most certain; influenza, alcoholism, erythromelalgia, cold, contusions, and previous thrombosis or phlebitis may be regarded as more or less important factors in originating the disease. Diabetes sometimes causes gangrene by exciting this disease.

*Treatment.*—There is little to say on the subject of treatment. In the earlier and less advanced stages of the malady prolonged rest of the affected part is certainly called for. Local warmth should be carefully supplied. Anodynes often in large quantities may be necessary for the relief of pain. Massage carefully carried out has also an important influence in furthering the opening out of collateral vessels, in promoting absorption through the lymphatics, and in freeing the muscles and other tissues of their waste products. In the acute stage the parts are too tender to admit of it; in all early cases it must be most cautiously employed; where the disease seems to be arrested and we have to deal with its effects only it may be used a little more vigorously. Small mummified areas may be left to separate naturally, especially in the hand. For more extensive gangrene, which is always, I believe, of the "mixed" form, amputation is necessary; the relief to pain that the operation affords always reconciles the patient to the mutilation The operation should be done high above the gangrenous spot and at a place and by a method that throws least strain upon the vessels of the part. Thus amputation through the lower part of the thigh is to be preferred to disarticulation at the knee and musculo-cutaneous flaps are to be chosen in preference to skin flaps.

WOMEN AS SURGICAL OPERATORS.—At the annual meeting in connexion with the New Hospital for Women, Euston-road, Sir Thomas Smith, Bart, K.C.V.O, F R C.S Eng., referred to the surgical work done at the New Hospital for Women. At that hospital, he said, women surgeons had gained a reputation for good surgery and had dissipated all prejudice which had existed against them. There had been attended at that hospital upwards of 1900 cases of maternity and up to within a short time of that meeting he could have said that among those cases there had been no deaths. The case he referred to, however, was not a maternity case, and so they had 1900 cases of maternity attended from that hospital without a death. 577 major operations had been performed with a mortality of under 6 per cent. He had been allowed personally to attend the operations in the operating theatre of the hospital, and he had very great pleasure in stating that he had nothing but admiration to express for the great dexterity and celerity with which the operations had been performed.

ABSTRACT OF

# The Hunterian Lectures

ON

# THE ANATOMY, PHYSIOLOGY, AND PATHOLOGY OF THE IMPERFECTLY DESCENDED TESTIS.

*Delivered before the Royal College of Surgeons of England on Feb. 24th, 26th, and 28th, 1902,*

BY W. McADAM ECCLES, M.S. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY; SENIOR ASSISTANT SURGEON, WEST LONDON HOSPITAL; ASSISTANT SURGEON, CITY OF LONDON TRUSS SOCIETY.

## LECTURE III.[1]

*Delivered on Feb. 28th.*

### PATHOLOGY—(*continued*).

*Cysts of the imperfectly descended testis.*—There are at least four varieties of cysts that may be developed in connexion with the testis that has failed to reach the scrotum. These are: (1) cysts formed upon the epididymis; (2) cysts found in the testis proper; (3) cysts due to fœtal remains; and (4) dermoid cysts, teratomata.

1. Cysts in connexion with the epididymis.—Like the cysts derived from the epididymis of the fully descended organ, so those found associated with the arrested gland are of two varieties, the small and the large. In the former the cysts never tend to enlarge to any but a comparatively small size, certainly not greater than that of an ordinary cob-nut. They are not therefore of much clinical importance. In the latter there is a tendency for the cysts to grow and they may assume such proportions as to become of very definite clinical significance. Small cysts in the epididymis of the fully descended organ are uncommon before the age of 40 and almost unknown previous to puberty. In the imperfectly migrated gland, on the other hand, they may appear earlier and more frequently than this. They may be sessile or pedunculated. When of the latter form they occasionally give rise to the production of loose bodies in the tunica vaginalis of the testis. Not infrequently they are multiple and sometimes they are very numerous. When pedunculated they cause small balloon-shaped swellings, very firm to the touch, almost giving the impression that they are of a solid nature. When sessile they raise the serous membrane so as to produce small oval or hemispherical tumours, also with the feeling of extreme hardness If punctured a clear fluid, as a rule, escapes, which but rarely contains spermatozoa. It is possible that rupture of one or more of these small cysts may lead to the production of a vaginal hydrocele on account of some irritation set up by the extravasated fluid These small cysts owe their origin to one of two sources. Either they are involution cysts due to the distension of previously existing cavities or they are connected with some fœtal remains, and are therefore cysts of congenital origin If they are derived from the blockage and dilatation of the ducts or tubes of the epididymis they must be formed in the depths of this structure and gradually reach the surface, there to elevate the serous covering of the tube and in some cases to become pedunculated, possibly as the outcome of the almost constant pressure and movement to which they are likely to be subjected. Further, should this view of their origin be correct it would be thought that there ought to be a definite communication between the ducts of the epididymis and the cavity of the cysts themselves. It is doubtful whether such has ever been shown to exist, for by careful injection of the ducts with mercury none has ever penetrated into the interior of the cysts, and it is but rare to discover any traces of spermatozoa in the fluid even of those cysts which are found associated with a normally placed and developed testis. But in spite of these facts it does not necessarily follow that a communication

---

[1] Lectures I. and II. were published in THE LANCET of March 1st, 1902, p 569.

a month or so the toes were quite gangrenous. All this time the patient suffered very severe pain. The urine was sometimes quite normal; more often it contained just a trace of albumin. Nothing was detected abnormal in the arteries of the upper limbs. On May 27th the urine was noticed to be of a dark orange colour, of specific gravity 1020, no albumin or sugar. This colour persisted up to the man's death. Albumin was sometimes present in small quantity. It did not give the reaction for blood-pigment, bile, or indican. On the 31st the gangrene of the foot was found to be extending towards the heel. He was frequently sick and was unable to retain any food. On June 3rd the vomiting, with much retching, returned, and persisted until the man died from exhaustion on the 8th. On the 7th a tumour was discovered occupying the greater part of the lower half of the abdomen. Its outline was indistinct and it was dull on percussion. Above it percussion revealed a distended stomach. This "tumour" was not present three days before, it was uninfluenced by emptying the bladder by a catheter.

At the post-mortem examination a gumma was found in the liver as well as definite syphilitic infiltration; the vessels of the liver were not thickened. A gumma was also found in the spleen. The lower 21 inches of the ileum were firmly adherent to the anterior abdominal wall and to each other. This portion of the intestine was purple-black in colour, without any peritoneal lustre, and its coats were greatly thickened by an infiltration of coagulated blood, so that its lumen was considerably diminished. The intestine above this was greatly distended. The colon was filled with feculent material of a dark coffee-ground colour. The mesentery corresponding to the affected part of the bowel was much thickened from extensive hæmorrhage into it. The superior mesenteric vein was distended with a thrombus quite up to the commencement of the portal vein. The superior mesenteric artery was markedly thickened and its lumen was almost obliterated in parts. A thrombus extended from the upper end of the left external iliac artery to the popliteal artery, and on the right side a clot extended from the upper end of the external iliac artery down into the tibial arteries two inches below the bifurcation of the popliteal. The heart was healthy and the abdominal aorta was healthy except for small areas of atheroma around the mouths of branches. A microscopical examination of the vessels showed distinct thickening of the intima of the superior mesenteric artery with a loose connective tissue; in the arteria dorsalis pedis there were similar changes except that the endothelium, though irregularly thickened, had a dense structure as compared with the loose one seen in the mesenteric artery.

In this case the cause of the disease was probably syphilis. There were old endarteritis of the vessels in the feet, more recent extensive thrombosis of the arteries above, and in addition arteritis and (possibly) phlebitis of the superior mesenteric vessels with thrombosis leading to great hæmorrhage into the walls of the intestine with corresponding loss of function.

I have seen two cases of this disease in the upper limb, one of which is very fully recorded in Vol. xvii. of the Transactions of the Clinical Society.

CASE 7.—This case occurred in a young brickmaker. The painful illness extended over about eight months and the main arteries of the limb were gradually obliterated up as high as the upper end of the brachial artery. There was gangrene of the tips of two digits. While the disease was active the pain was most intense.

CASE 8.—This case occurred in the right arm of a woman between 30 and 40 years of age whom I saw on one occasion only as she was passing through London. After an attack of influenza she began to suffer with severe pain in the right hand and forearm, made worse by using it and by exposure. The pain was attributed to neuritis; remedies had no effect upon it. When I saw her she was much better and was returning home after a visit to Bournemouth. I found the radial, ulnar, and brachial arteries as high as the middle of the arm converted into firm pulseless cords; the forearm was a little wasted, tender, bluish red in colour, not so warm as its fellow, and painful if allowed to get cold. The other arteries of the body and of the heart were healthy; so was the urine.

CASE 9.—A man, aged 43 years, was seen by me once only in 1896. He had lived a healthy active life and there was no history of rheumatism, gout, or syphilis. In the autumn of 1890 when out shooting he suddenly felt his right leg become cold, weak, and painful; this was not due to any injury, strain, or exposure to cold. He lay up for many weeks at the suggestion of his medical man who told him that there was no pulse in his posterior tibial artery. He remained well until September, 1891, and then, again when out shooting, he was seized with the same kind of pain in his left foot. This attack was more serious than the former one; the pain was very severe, and the second toe became almost gangrenous. Among others he was seen by M. Charcot who prescribed prolonged rest in the recumbent position. He rested the leg for six months. After that he had two attacks of phlebitis—one in each thigh. When I saw him in 1896 he could walk with comfort for 100 yards, but then a painful sense of weakness in the legs came over him. When standing he was always desirous of sitting or lying down. Each leg was slightly œdematous and the circulation in the feet and lower part of the leg was distinctly sluggish. On the right side there was no pulse in either of the tibial arteries; on the left side there was no pulse in the anterior tibial and only a slight one in the posterior tibial vessel. Both femoral arteries were normal and so were the arteries of the head and neck. There was no disease of the heart or any sign of aneurysm; the urine was 1018, acid, and free from albumin and sugar. The liver and spleen seemed to be healthy. I recommended this patient to use his legs a little more and to have them carefully massaged. I have not seen him since. The history of this case is certainly peculiar. The sudden onset of the symptoms is suggestive of embolism, but there was no obvious source of such. The recurrence of the attack under exactly similar circumstances is striking, and yet I cannot see what clue it gives us. In other respects the case resembles endarteritis, and in each leg the obliterated vessel could be clearly demonstrated.

These cases illustrate several points in the history of this affection in addition to those which I mentioned in my preliminary summary. I will refer to a few of them. The *extreme chronicity* of the process is well exemplified by Cases 2 and 6, where it had been going on for three and a half years before I saw the patients. Cases 3, 4, and 5 are, on the other hand, examples of a more acute form of the malady, and intermediate grades are furnished by Cases 1, 7, and 8. The *pain* which is experienced by these patients is generally very severe. I have never seen stronger evidence of extreme pain in anyone than I witnessed in the young man whom I saw in 1884 (Case 7). He often writhed on the floor in agony that even large doses of morphia had little effect in controlling. Pain is the earliest symptom noticed; it has been described as "rheumatic," also as pain in the bones; it is referred to the deep structures of the part and is aching in character, and the intensity of this ache may culminate in an agony. It is often worse at night, is generally made worse by use of the part, and is always aggravated by exposure. The *ischæmia* varies in degree. As a rule there is not much alteration in colour until gangrene is threatened; what there is is blotchy in distribution and dull red. It is specially noteworthy that it is not accompanied with anæsthesia. There may be slight wasting of the part or swelling from œdema—this generally due to venous obstruction. The *gangrene* may be a slow mummification or a more rapid sphacelation; in some cases the parts preserve their consistence and proportions quite remarkably, being neither "dry" nor "moist." This variation, no doubt, depends upon the degree to which venous obstruction is associated with the arterial obstruction, if, indeed, it is present at all. The case which Dr. Pasteur has allowed me to use (Case 6) showed the extreme degree of venous thrombosis in the mesentery with extensive hæmorrhage into the bowels and between the layers of the mesentery. Another feature of the gangrene often noticed is its patchy distribution—in some cases, no doubt, it is total up to a given level (Case 3), but in others (e.g., Cases 1 and 2) separate areas of the foot necrose. This is easily explained by the irregular extension along the arteries of the obstructive disease. *Fever* is usually present when the disease is active (see Cases 1, 2, and 7), and other constitutional effects may be witnessed, such as wasting, loss of appetite, and delirium. The state of the *other arteries* of the body is naturally laid great stress upon in diagnosis. Widespread atheroma or calcification affords an obvious explanation of interference with the circulation in distal parts; but, of course, this disease may occur in patients who manifest some degree of atheroma, and an instance of this is afforded in Case 1.

*Sex.*—The disease is certainly more common in men than in women—in my cases in the proportion of seven to two mixed-celled variety. These two sarcomata are of rapid growth, commencing generally in the connective tissue of the body of the gland, being but rarely primary in the epididymis. At first the new growth is confined within the tunica albuginea of the testis and is often surrounded with fluid in the tunica vaginalis, which fluid is not infrequently blood-stained. As the growth advances it transgresses the confines of the tunica albuginea and involves the surrounding structures. Usually, however, lymphatic glandular infection or secondary deposit in viscera has taken place before considerable local extension has occurred. The sarcomatous elements often in the imperfectly descended organ appear first in the connective tissue forming the walls of the poorly developed seminal tubules, or in the tissue found between these parts. The invasion of the round or spindle cells displaces the tubules further and further from one another and at the same time compresses them so that their shape becomes completely altered, their lumen entirely obliterated, and their imperfect epithelial cell-lining destroyed. The deposition of interstitial fibrous tissue in these sarcomata is not uncommon and in some instances it is present in a marked degree. No instance of cartilage being present with the sarcomatous elements in a testis which has not reached the scrotum is on record. This is a matter of some interest seeing that cartilage is comparatively frequently found in the spindle-celled sarcoma of the fully descended organ. The testis is extremely rich in minute lymphatic vessels which surround the tubules and, uniting to form larger vessels, run in the septa between the compartments of the gland. Most of the lymph is conveyed by these channels to the corpus Highmori and thence by way of larger vessels, constituting the lymphatics of the cord, to the lumbar lymphatic glands. Efferent vessels from these glands pass to the receptaculum chyli, and thus in one case at least there was an enlargement of the left supra-clavicular glands in sarcoma of an inguinal testis. Secondary growths in every way resemble the primary lesions. They may be found in the lungs, liver, spleen, and peritoneum, in addition to the lumbar glands. Blood-vessels, particularly the inferior vena cava, are sometimes the site of the secondary deposits whereby a blocking of their lumen is caused which very seriously impedes the return of blood from the lower extremities. Œdema may also be produced by the direct pressure upon the vena cava of an intra-abdominal sarcomatous testis or by the diseased lymphatic glands in the right lumbar region. By microscopical examination there will be seen either round or spindle cells disseminated in the meshes of the connective tissues of the gland, and in some instances it is difficult to say whether the trabeculæ present are those which originally existed in the gland or are themselves part of the new growth. As in cases of sarcoma of the fully descended organ, there is but little recorded that is of much value as to the real cause of the sarcoma of the partially descended testis

On analysing a considerable number of instances of sarcoma of an imperfectly migrated testis—in fact, all those which it has been possible to find in medical literature up to the present year—some interesting facts become apparent. It will be found that the disease begins most usually between the ages of 20 and 40 years, and it is therefore a disease rather of middle life. Sarcoma of the fully descended gland is not uncommon in quite young boys. There does not seem to be any marked difference as to which side the new growth attacks. This is not altogether in accord with the fact that the right testis is the one that is most frequently the seat of arrest. There is, therefore, possibly some reason why the testis on the left side should be more frequently the seat of the new growth, but none suggests itself to me. The position that the testis has been found in when diseased is also of interest. Inguinal inclusion is the most common place for the arrested testis to be found, and thus it is the general position in which sarcomatous imperfectly descended testes are discovered. After this position the abdominal retention is the next most productive of a malignant new growth, which again is of interest from the fact that abdominal inclusion is not the second most common position for the testis to be found, just below the superficial abdominal ring being more usual.

A definite history of an injury, such as a blow, a squeeze, &c., is not infrequently given in the cases where sarcoma attacks the testis lying in the scrotum, but when the lesion affects the imperfectly descended testis a predisposing cause of this nature is not nearly so common or so clear. On the other hand, it must be remembered that the testis which lies in the inguinal canal is subjected to numberless though probably slight occasions of violence, which may pass in the greater number of instances without any notice being taken of them. As was shown when inflammation of the arrested organ was being discussed, muscular effort, blows, extrusion of the organ suddenly through the deep or through the superficial abdominal ring, all contribute to the onset of inflammation and possibly also to the incidence of neoplasms. When the testis is retained within the abdominal walls it cannot be so exposed to the risk of injury, and yet it has been seen that the abdominal inclusion does not by any means protect the gland from the onset of malignant disease. It is conceivable that the pressure to which the testis is so repeatedly subjected when it lies in the inguinal canal may produce such an effect upon the ill-developed gland as to induce some fœtal relic within it to start into malignant activity in the form of a sarcomatous growth. On the other hand, it is possible that some injury may result in the formation of reparative material which being arrested at that stage when its cells so closely resemble those of sarcoma this new growth may actually later derive its origin from this source. And, lastly, it is possible that the injury to which the testis is exposed may result in such an inflammation that the tissues of the gland are unable to withstand the ingress of parasites, should such be the essential cause of the new growth. Previous inflammation, other than that which has been due to trauma, is rare also apparently in cases of new formation in the arrested testis. There is, however, at least one case in which the malignant trouble was preceded by a double orchitis secondary to parotitis, but the interval of time between the two affections was considerable—namely, 23 years.

An associated hernia is such a common complication of an imperfectly descended testis that caution must be used in considering that it has any influence on the production of malignant disease, though this has been much asserted by some observers. In the 854 instances of arrest of the testis accompanied by hernia which have been already mentioned in no single instance was a sarcomatous growth also present. Further, out of 26 cases of sarcoma of the imperfectly descended testis only two had a hernia associated with the new growth, and in neither of these did the protrusion seem to have any bearing whatever on the production of the neoplasm. Two other patients had worn trusses for supposed herniæ, but only with a possible relation to the onset of the new growth in one. But there are two facts that must be taken into consideration under this heading—namely, that many instances of imperfect descent of the testis are mistaken for hernial protrusions and a truss is applied, and also that a hernia is in reality so frequently present with the arrested testis that a truss is needed, and therefore most of the cases in which a sarcoma has developed were in patients who had been wearers of trusses. It is, however, extremely doubtful whether a truss worn over the inguinal canal in the case of an inguinal inclusion of a testis really does produce harmful pressure on the gland provided that the truss is of right construction and size. On the other hand, the pressure of a truss if applied over a testis that is lying just below the superficial abdominal ring is ever prone to excite the occurrence of inflammation in the organ, but sarcoma, as has been seen, is rare in a gland so placed Heredity does not seem to have the slightest influence on the production of sarcoma of the imperfectly descended testis. The persistence or not of embryonic traces or cell elements—possibly such as might reasonably be termed "rests"—in testes that have failed to reach their normal resting-place is a matter which requires a closer histological investigation and for this purpose, among others, every imperfectly descended testis that is removed should be submitted to a rigid microscopic examination. Further, in every castration for early sarcoma—and such early removal should be of increasing frequency, and whether the gland affected is an imperfectly or a fully descended one—the testis should be considered as likely to throw some light on this till now obscure question of etiology.

It is well recognised that vestigial elements in imperfectly developed organs are peculiarly liable to give origin to malignant growths As was shown in the first lecture, the examination of testes which have failed to reach the scrotum reveals in most of the instances two distinct abnormalities Firstly, the seminiferous tubules are atrophic or undeveloped and present no signs of spermatogenesis; and may not have existed at an earlier period in the formation of the cyst than the one that was taken for the injection experiment and that the aperture may have become obliterated. Spermatozoa, moreover, may in time become completely disintegrated in the fluid in which they lie. Another argument in favour of this origin of these small cysts is the fact that the epithelium lining their wall bears a close resemblance to the epithelium of that which lines the ducts of the epididymis The senile changes which occur in the epididymis when the testis is fully descended and the similar changes which take place in the testicular tissue of the organ that has failed to reach the scrotum consequent upon repeated attacks of inflammation both go to prove that there is an increase in the interstitial connective tissue. This new fibrous tissue, by a process of contraction to which it is ever prone, may bring about the obliteration of portions of certain ducts with a dilatation of that part which remains patent.

With regard to the theory that these small cysts of the epididymis owe their origin to the dilatation of fœtal remains, such as traces of the Müllerian duct, in favour of it may be advanced the fact that the enlargement usually occurs close to the spot where such remains are likely to be left, and against it is the knowledge that they seldom, if ever, are found in quite early life, a period of existence in which it might be thought that they would have been common.

The large cysts of the epididymis of the retained testis have their origin altogether within the substance of the epididymis in the majority of instances and are probably closely connected with the seminal tubulès or the ducts of the epididymis. They are usually single, have a tendency to increase in size so that at times they assume considerable proportions, they often contain spermatozoa when the gland to which they belong is functionally active, and they can be readily palpated from without. They are generally found during the period of sexual activity and are therefore more common at an earlier age than the small cysts of the epididymis which have been just dealt with. The fluid that they contain is, as a rule, limpid and colourless or slightly milky. Occasionally the contents may be straw-coloured, more like the fluid found within an ordinary vaginal hydrocele.

There are, again, two theories as to the causation of these large cysts of the epididymis. They may in the first place be derived from the dilatation of one of the seminal tubules, one of the vasa efferentia, one of the ducts of the epididymis itself, or even in the sac that may result from the inflammation produced by the rupture, traumatic or spontaneous, of a seminal tubule. There is no doubt about the fact that spermatozoa in the active gland are generally present in the fluid of the encysted hydrocele, and that this proves a direct communication probably between the sperm-producing testis and the connected cyst. Further, the origin of some of these large cysts sometimes from fœtal remains is certain, and in these instances the sac will not contain any spermatozoa. Large cysts of the epididymis are not common in association with the imperfectly descended testis.

2. Cysts in connexion with the testis proper.—That the tissue forming the testis proper can originate cysts is a fact that is well recognised. They have been for the most part designated simple cysts or cystic fibroma of the testis. They are found in connexion with the imperfectly descended testis as well as in that organ which has reached the scrotum. They are, perhaps, more usually seen in the lower animals than in the human subject. Sometimes the cyst is derived from the tissue forming the corpus Highmori and its walls are then lined with ciliated epithelium.

3. Cysts in connexion with fœtal remains.—Attention has been already drawn to the fact that cysts in connexion with the imperfectly descended testis are derived from the dilatation of certain fœtal remains, and perhaps more frequently so in the arrested testis than in the one that has fully descended. They are extremely interesting, and may be classified as follows: those derived (*a*) from the hydatid of Morgagni; (*b*) from the Wolffian tubules; (*c*) from the vasa aberrantia; and (*d*) from the paradidymis. These cysts vary much in their characters. One which was found in the abdomen of a sheep, considered before death to be of the female sex, occupied the pelvis. It was four and a half inches in diameter. The vas deferens of the same side was thin and membranous and impervious save at its termination. It was lost on the wall of the cyst, which was filled with a greenish-grey putty-like substance and composed chiefly of a fatty material. Part of the cyst wall was covered with outspread bands of striped muscle. The cyst was composed of an inner layer of embryonic tissue of round cells, a middle layer of spindle cells, and an outer layer of fibrous tissue; these three layers probably represented the different stages in the development of the tissue. The cyst was either an undifferentiated genital gland, or it had been developed in connexion with the remains of the Wolffian body. Another cyst that I have examined was formed from the left testis which was removed from the abdomen of a horse, aged two years The right testis was normal and had been removed from the scrotum three months earlier. The left testis was converted into a cyst of about the size of a walnut, the cavity of which contained a fatty, sebaceous-like material and in the centre of it a worm, probably a strongylus armatus, which had reached the gland almost certainly by passing down the spermatic artery. I have further lately seen an almost similar specimen, in which again a strongylus was found.

4 So-called dermoid cysts of the testis that have reached the scrotum have been undeniably observed, although it is no doubt true that some of the specimens that have been recorded are more likely to have been dermoids derived from the scrotal tissues rather than from the testicular body. I have not been able to trace a record of a true dermoid cyst of an imperfectly descended testis in the human subject, but there are several recorded in animals, and particularly in the horse. In these latter animals they have been shown to present similar characters to the common dermoids found in the human ovary, and probably their origin is somewhat the same. They may be in reality an attempt on the part of nature to produce a descendant from germinal epithelium which has remained from the primary genital mass but undifferentiated, and this abortive development, being without the help of the union of cells of the two sexes, results in the formation of the heterogeneous mass of sebaceous matter, teeth, ossifying cartilage, bone, hairs, &c. It is conceivable that the testis, and especially the imperfectly descended one, may contain the same or similar cells to those which the ovary does and from which this curious growth takes its origin. Finally, it must always be borne in mind that cysts may develop in connexion with malignant disease of an imperfectly descended testis, though such seem to be rarer than in the case of the gland that has passed into the scrotum.

*Malignant new growths of the imperfectly descended testis* —Both sarcoma and carcinoma may attack an imperfectly descended testis, but the mesoblastic neoplasm seems to be of rather more frequent occurrence than the epiblastic. Sarcoma of a testis, whether of the fully descended or the partially migrated organ, is a comparatively rare disease. Considering that every male, except an infinitesimal minority, has at birth two testes, wherever they may be situated, it follows that the number of testes that might become the seat of a new growth of a malignant character is enormous, yet the instances of such lesions admitted into large hospitals are decidedly small. From the published statistics of one hospital at which over 4000 males are annually admitted there were only 38 cases of sarcoma of the testis, whether fully or imperfectly descended, seen in 15 years, giving an average of two and a half cases a year. It is a matter of extreme difficulty to determine satisfactorily whether a testis that has not reached the scrotum or has passed into an abnormal position is proportionally more liable to become attacked with sarcoma than one which is situated in its usual place. In the 38 cases which have just been alluded to only one was in a testis which was imperfectly descended, the gland lying in the abdomen and belonging to the left side. In a close examination of 48,000 males with hernia 854 had imperfect descent of one or both testes, or one in every 56, and none of these presented any form of malignant disease of the testis, though many had had attacks of inflammation of the testis, and in some instances these had been often repeated. The forms of sarcoma that affect the testis when it is retained are similar to those that occur in the normally placed gland, although there are not, so far as I have been able to determine, instances of every variety. The varieties as a rule met with are: the round-celled, whether chiefly of large or small cells, the spindle-celled, the mixed-celled, and the myxo-sarcoma. Chondro-sarcoma, lympho-sarcoma, and melano-sarcoma have not apparently been observed in connexion with a partially descended testis. Round celled sarcoma is undoubtedly the most usual form to occur, and after this the

secondly, there is a distinct increase in the interstitial cellular elements. It is open to question whether these latter cells, which appear in so much larger numbers than they do in normally placed testes, have an epithelial or mesoblastic origin. If epithelial, then they may be the remains of the lining of aborted seminiferous tubes; if mesoblastic, probably they are the remnants of the Wolffian body. Although there does not at present seem to be sufficient evidence definitely to determine their source, yet on the whole it would appear that they owe their existence to mesoblastic rather than to epiblastic tissue The cells, moreover, are somewhat like those of the adrenal, particularly the cortex of this structure, but it is doubtful whether they can be taken as the remains of such. As has been stated, the majority of malignant growths of the testis which has been arrested are of a sarcomatous nature, and the occurrence of these interstitial cells may therefore be an explanation of this frequency.

While it has already been noticed that carcinoma of the imperfectly descended testis is less common than sarcoma of the gland, yet it is probable that this is even more distinctly so from the fact that many of the cases which have been recorded as "cancer," "encephaloid," or "medullary" disease by the older writers were in reality examples of sarcoma rather than of carcinoma. Several varieties of carcinoma are met with in the imperfectly descended testis: the encephaloid or medullary, the schirrous and the colloid, and, lastly, a rare form of chondro-carcinoma. The cells are spheroidal, oval, or polygonal. They are abundantly rich in protoplasm, and do not, as a rule, have very distinct outlines, both of which peculiarities are strong evidence of their epithelial origin. The most probable source of the cells, and, therefore, the growth of which they form the chief part, is from the imperfectly formed epithelial elements of the seminal tubules. Another reason why carcinoma of the arrested testis is comparatively uncommon may be found in the fact that there is so little active epithelium present in the poorly developed organ. In the fully descended gland the tubular epithelium is constantly, between puberty and the involution of the testis, undergoing division and subdivision for the formation of spermatozoa, a condition which has a predisposing influence upon the incidence of carcinoma.

While sarcoma of the arrested testis occurs most usually between the ages of 20 and 40 years carcinoma is, on the whole, a disease of rather later life—namely, between the ages of 30 and 50 years The two sides of the body are equally liable to the affection. Of the more recent cases in which the microscopical examination has proved the presence of undoubted carcinoma the testis has been found in the abdomen, the inguinal canal, and just below the superficial ring. There is no record of a case of carcinoma of the testis when lying in the perineum or in Scarpa's triangle.

With regard to causation, injury would seem to have rather more association with the onset of carcinoma than it had with the development of sarcoma, and this particularly when the testis has been lying in the inguinal canal Previous inflammation has apparently no very definite bearing upon the origin of the disease In a few instances there has been a history pointing to some hereditary influence. Secondary glandular and visceral infection is very rapid in its appearance and the case runs a peculiarly quick and fatal course.

*Hydrocele in connexion with imperfect descent of the testis.*—When the testis is arrested within the abdominal cavity no tunica vaginalis testis is developed, and therefore there can be no intra-abdominal hydrocele formed. But when the organ has passed beyond the bounds of the abdominal wall, then a processus vaginalis testis will always be found of a smaller or greater extent, and a hydrocele may therefore be in evidence Further, it is true that when a testis is retained within the abdomen sometimes a processus vaginalis may be drawn down into the inguinal canal, the scrotum, or even into the perineum or Scarpa's triangle. It is possible, then, to have a hydrocele outside the abdominal wall with a testis which is completely retained within that cavity. A short classification of hydroceles in connexion with imperfect descent of the testis may be given as follows: inguinal, scrotal, bilocular, and trilocular, peritoneal, and in Scarpa's triangle. An inguinal hydrocele may be further subdivided into two classes—one in which the testis is still within the abdomen and the other in which it is lying in the inguinal canal. When the testis is within the abdomen the processus vaginalis may still communicate with the general cavity of the peritoneum, or it may be shut off from that space, and the same difference may be found in association with the inguinal testis. When the processus vaginalis has been formed, but the testis is arrested within the abdomen, it is usual for the pouch of peritoneum to remain in communication with the general cavity of the serous membrane. Fluid, therefore, which may be found in it has either been formed *in situ*, or has drained down from the peritoneal cavity In both cases it will be freely reducible, or rather it will flow back into the abdomen when the patient assumes the horizontal posture. When the communication is obliterated, then, when fluid collects, there will be irreducibility and the cyst will present all the signs of an inguinal hydrocele of the processus vaginalis, except for the fact that a testis can never be felt within it.

Inguinal hydrocele with the testis in the canal is the most common form of hydrocele in association with an arrested testis. When there is a communication of the processus vaginalis it may be either a very free one or it may be blocked by the testis. When the tunica vaginalis is shut off from the general cavity of the abdomen the hydrocele may be unilocular or multilocular. The fluid found within is of the ordinary serous hydrocele nature or is inflammatory in its origin and characters In a certain number of instances the testis, when it occupies a position at the upper limit of the canal, acts as a plug to the deep abdominal ring and thus prevents the return of the fluid within the sac except under special conditions. Unilocular hydroceles with the communication with the abdominal cavity shut off may be acute or chronic, the acute being as a rule due to inflammatory attacks, while the chronic is probably caused by slight recurrent inflammations. The multilocular hydroceles are the outcome of inflammation, which has not only caused the formation of the fluid but has led to production of adhesions which have divided up the cavity of the tunica vaginalis. Truss pressure is not a marked cause of hydrocele, for out of 936 cases in which a truss had been worn only 32 were complicated by a hydrocele. A scrotal hydrocele is one in which the processus vaginalis testis has passed into the scrotum beyond the place of the arrest of the accompanying testis. As a rule, that part of the pouch which lies below the superficial abdominal ring becomes shut off from the rest before the onset of the hydrocele. Such a condition is not so very uncommon. The presence of the fluid in the upper part of the scrotum may be mistaken for the testis in its normal position, particularly if the scrotum on that side is fairly well developed and there is no evidence of any inguinal swelling. These scrotal hydroceles do not, as a rule, reach any great size. The peritoneal process accompanying the testis is by no means infrequently drawn down into the scrotum beyond the site of the arrested testis and in such a case the original communication with the general cavity of the abdomen may remain patent or it may become cut off. If it is closed, then all the conditions necessary for the development of a bilocular hydrocele are present and the same may be said of those instances in which the imperfectly descended testis acts as a plug at the deep abdominal ring, preventing the return into the abdomen of any fluid which has collected in either portion of the processus vaginalis, the inguinal or the scrotal. Distension, therefore, of the inguinal and scrotal parts of the peritoneal pouch will lead to the formation of one variety of bilocular hydrocele and a swelling will be apparent both in the groin and in the scrotum. Both of these portions may be tense or one may be lax and the other firm, and on pressure being applied to the less tense sac the other will become more firm immediately. Fluctuation can also be readily obtained through from one to the other As a rule, both portions are translucent and although the inguinal portion may have a forward impulse on coughing, the scrotal part is not thereby affected. When the communication with the abdomen is cut off, the fluid in both of the swellings will be irreducible Where an aperture still exists, even though the testis may block the opening, there will be variations in the fulness and the tenseness of the swellings, and under certain conditions the whole of the tumour may be made to disappear by reason of the reduction of the fluid. If the inguinal portion can be emptied the testis, smaller than normal, can usually be readily palpated in the inguinal canal and generally at the upper end of that passage. In some instances the scrotal portion of the sac may be completely shut off from the inguinal part and both become distended with fluid. This separation is commonly at the site of the superficial ring.

A second variety of hydrocele occurs when the testis is arrested whether within the abdomen, in the inguinal canal, or just below the superficial ring, and that portion of the processes vaginalis which lies in the canal becomes distended with fluid and, being unable to contain more without further space, a secondary sac is formed in one of the planes of the abdominal wall. Sometimes this additional portion is protruded in the space between the aponeurosis of the external oblique and the muscular tissue of the internal oblique muscles. In other cases, less common, with the testis lying without the superficial ring, the primary pouch of peritoneum also traverses the same aperture, and then, instead of entering the scrotum, which may be practically absent, mounts upward and outward on the abdominal wall in the plane between the aponeurosis of the external oblique and the skin.

The third variety is very rare and consists of a secondary sac lying in the extra-peritoneal tissue behind the body of the os pubis in the pelvis. The three varieties may be respectively termed the deep interstitial, the superficial interstitial, and the properitoneal. Sometimes the superadded sac may become of enormous size and may mount up on the abdominal wall so as to lie in such position as to simulate a hydronephrosis.

A few instances of trilocular hydrocele have been seen. In these there is, in addition to the two pouches of the bilocular hydrocele just described, a third pouch which lies in the upper part of the scrotum. The arrested testis is to be found either in the canal or just below the superficial ring. Probably in the majority of instances the inguinal and the scrotal portions are the first to be formed and subsequently the interstitial diverticulum is produced. When the testis has passed into the perineum the processus vaginalis that accompanies it may become the site of a collection of fluid, usually as the outcome of an inflammatory process in the ectopic organ. In like manner a testis which has passed into Scarpa's triangle is liable to have its surrounding peritoneal sac distended with fluid as the outcome of inflammation.

*Hernia in association with imperfectly descended testes.*—It is probable that a hernial protrusion is the most frequent pathological condition associated with imperfect descent of the testis. The exact frequency in which inguinal hernia accompanies imperfect descent of the testis is difficult to estimate, but from a review of a large number of cases it is distinctly more than half. As has already been seen, in the majority of cases of arrested testes there is an associated want of formation or arrest of development of the annexa. Thus it happens that there remains a patent process of the peritoneum into which abdominal viscera may descend. It is, however, necessary, as in the herniæ of congenital type with a testis normally placed, that there should be some other besides this primary predisposing factor, and, indeed, other than the imperfect development which so often accompanies imperfect descent. Neither of these two factors is in itself sufficient actually to determine protrusion. 35 per cent. of the cases of herniæ with arrested testis occur in the first year of life, while of those in persons who are not affected with imperfect descent, only 7·7 per cent. commence before 12 months of age, showing that the congenital defect has an undoubted influence on the onset of the protrusion. Inguinal and abdominal inclusion favour the early development of a hernia. The exciting causes may be such as are present in other so-called congenital herniæ—viz., disease of the lungs, over-distension of the abdomen by intestinal gas, obstruction to the outflow of urine, constipation, and other less common conditions. It may be also true that the presence of the testis in the inguinal canal may in itself prevent the proper sphincter-like action of the lower fibres of the internal oblique and transversalis. This and other reasons would seem to show that the position in which the testis is arrested plays an important part in the frequency with which a hernia is developed.

There are at least five varieties of inguinal hernia associated with imperfect descent of the testis—namely, bubonocele, scrotal, interstitial, cruro-scrotal, and superficial perineal As would be naturally expected a bubonocele is the most frequent form of inguinal hernia to be met with in association with imperfect descent of the testis. It is, moreover, the early stage of several of the other varieties. With the non-closure of the processus vaginalis nothing is more likely to happen when the testis is lying in the inguinal canal than that some of the abdominal viscera should prolapse into the waiting sac The same may happen when the testis is completely retained within the abdomen, provided that a peritoneal pouch has entered the canal and has remained patent. As a rule the testis can be palpated and its exact position made out. Sometimes the contents of the sac will obscure the presence of the gland which, however, can be felt on the return of the viscera within the abdomen. The deep ring, the potential opening in the transversalis fascia through which the organ has entered the canal, is usually small and therefore strangulation, should it occur, is frequently very severe. There is generally an intimate relationship between the back of the peritoneal pouch and the short spermatic cord and their separation the one from the other may be a matter of some difficulty in a radical operation upon the hernia. In some cases there will be found adhesions between the contents of the sac and the upper part of the testis, thus rendering the hernia an irreducible one. In the history of the case it is frequently stated that the swelling which has been noticed in the inguinal region becomes larger on the advent of the hernia. A bubonocele may also be associated with a testis which has transgressed the confines of the inguinal canal and is lying in front of the body of the os pubis. Further, a scrotal hernia may be associated with imperfect descent of the testis. By this term is meant a protrusion which, having left the inguinal canal through the superficial ring, has passed into the scrotal tissue and has not distended the fold between the scrotum and the thigh. A scrotal hernia is further covered with dartos tissues and expands more or less the scrotum, which, until the entrance of the hernia into it, has remained undistended owing to the absence of the corresponding testicle. When the scrotum is but poorly developed then the hernia will actually have to dilate the parts so as to obtain room for itself. The explanation of the scrotal protrusion lies as a rule in the fact that a pouch of peritoneum is so frequently drawn down by the gubernaculum testis into the region of the scrotum beyond the site of the arrested organ.

By an insterstitial hernia is understood an inguinal protrusion, a part or the whole of the sac of which is placed in one or other of the planes of the abdominal wall, transgressing the ordinary limits of an inguinal hernia. Interstitial herniæ may be associated with imperfect or abnormal descent of the testis. On the other hand, they are also found present in males whose testes have reached their normal position in the scrotum. And further, they actually occur in female subjects in a proportion greater than in the male sex; and lastly, all instances of inguinal hernia associated with imperfect descent of the testis are not of the interstitial variety. These statements of fact go to prove conclusively that imperfect transition of the testis is not a necessary accompaniment of interstitial inguinal hernia. An examination, however, of a large number of cases of this form of protrusion in males leads to clear evidence that imperfect descent of the testis has a marked bearing upon a development of the hernia. Nearly 1 per cent. of inguinal hernia in male subjects is of the interstitial variety; 5 per cent. of those who show hernial protrusions with imperfect descent of the testis present one or other of the varieties of interstitial hernia. In males 73 4 per cent. of interstitial inguinal herniæ are associated with more or less imperfect descent of the testis. The position of the arrested testis is a matter of great interest in view of the relationship which undoubtedly exists between the imperfect descent and the interstitial sac. The position, however, which is observed is usually that which is found at the time when the patient presents himself for treatment, and it does not, therefore, necessarily imply that this was the site of the testis when the hernia first made its appearance. It is not common, however, for the testis to alter its position after the commencement of a hernia, though undoubtedly this may occur in some cases. In the majority of instances the arrested testis is found in the inguinal canal and at a position towards the lower end of that space. Next, it is most usually seen just below the superficial abdominal ring, and in some of these latter cases it is conceivable that it may have been pushed by the oncoming hernia through the superficial ring In a few instances it may be found lying on the aponeurosis of the external oblique and towards the anterior superior spine of the ilium, again having reached the spot by the pressure exerted by the protruded viscera.

Several theories have been advanced to explain the relationship between the arrest of the testis and the development of an interstitial hernia. First, there is the position of the testis itself, for if lying in the inguinal canal and especially if occupying a position at its lower and inner end, tethered by a short cord, it may act as a barrier to the of the contents of a hernial sac through the superficial abdominal ring. Repeated expiratory efforts drive the viscera into a patent processus vaginalis, and after a time tend to force the testis and the viscera from the canal through the superficial ring. The gland is, however, prevented from being extruded by its short cord and the peritoneal pouch dilates in the plane of least resistance, but on the other hand, the smallness of the superficial ring itself may be the cause of the imprisonment both of the testis and of the contents of the sac. Secondly, want of muscular development in the inguinal region is not infrequently present with a want of descent of the testis and may be a reason why the hernial sac insinuates itself in the planes of the abdominal wall, though it is open to question whether the abnormal condition of the muscles is not rather the result of the pressure exerted by the hernial protrusion than the cause of the formation of the sac. Thirdly, it is possible that some abnormal drag of the gubernaculum testis on a portion of the peritoneum near the abdominal opening of the processus vaginalis may cause adventitious pouches to be formed and these lead to the production of an interstitial sac.

There are three chief varieties of interstitial hernia usually described. In the first the sac is found between the aponeurosis of the external oblique and the muscular fibres of the internal oblique and this is the one which is most frequently associated with arrest of the testis. It usually presents an external swelling which is very characteristic in its shape and extent, beginning in the region of the inguinal canal, it mounts upwards and outwards towards the anterior superior spine of the ilium. The whole course of the gradual formation of the tumour can be observed if a patient, after the contents of the sac have been reduced, is directed to lie on his back and cough. There is no other condition that will give the spectacle of a gradually increasing tumour under these circumstances. The shape of the swelling is usually ovoid and its margins are fairly distinct. It is flattened on the surface and does not project far from the abdominal wall. The limits of the tumour may be wide and sometimes it reaches as high as the costal arch, sometimes it may overlap the rectus muscles or may even hang down in front of Poupart's ligament so as to simulate a femoral hernia. The contents of the sac can generally be reduced, though sometimes it is a difficult matter entirely to empty it. When reduction has been effected, the ill developed testis can be made out lying in the inguinal canal. When there is a scrotal portion as well as an interstitial, the former is usually secondary to the development of the latter and usually *indicates that the resistance to the increase in the* primary part has become greater than that to the entry of the viscera into the scrotum. The second variety of interstitial hernia is that in which the sac is placed between the aponeurosis of the external oblique and the skin. It also is not infrequently associated with an arrest of the testis. The method in which the sac has arrived at its position may be one of two. Either the peritoneum has been pushed forward and then upward through a gap in the aponeurosis, or the sac, at first lying in the inguinal canal, has transgressed the bounds of this space, protruded through the superficial ring and finding its way into the scrotum blocked has turned upward on the abdominal wall. In both of these the direction taken by the hernia is that of the least resistance for the attachment of the deep layer of the superficial fascia to the front of Poupart's ligament would bar its progress into the thigh. As a rule, the external swelling present in the second variety is more pronounced than that of the first. Some help may be obtained in the diagnosis between the two forms by requesting the recumbent sufferer to raise *his head and shoulders*, and thus throw into action the abdominal muscles when if the external oblique is placed in front of the sac the hernia will become more tense but will not evidently increase much, while if the aponeurosis be posterior to the bulk of the swelling then this will be markedly enlarged and its tenseness will only be augmented in proportion to its size. The third form of interstitial hernia is that in which the sac lies in the plane between the transversalis fascia and the peritoneum, that is in the extra-peritoneal tissue. This is a rare form and one which is not so commonly associated with imperfect descent of the testis. There is usually a scrotal portion of the sac in addition to the properitoneal. In almost every case the additional portion of the sac within the abdominal wall has not been recognised until after death or during an operation on account of the strangulation for there is no external swelling and it is rare that the deeper part of the sac can be palpated. There are two chief sites in which the secondary sac may be placed, one the iliac fossa and the other the prevesical region.

By a cruro scrotal hernia is meant a hernial sac which distends not the scrotal tissues but the fold of skin which is found between the scrotum and the thigh. The hernia, therefore, will be covered *with ordinary cutaneous tissue and* not with dartos. It is always associated with an imperfect or abnormal descent of the testis, and the hernia follows the organ. The testis, usually an imperfectly developed one, having left the inguinal canal, is for some reason—probably either a want of development of the scrotal tissue or a tenseness of the fascia at the entrance of the scrotum—prevented from continuing its further descent into that region. It will therefore remain permanently in the cruro-scrotal fold, or pass into the perineum or possibly into Scarpa's triangle. If the processus vaginalis testis which accompanies it remains patent *viscera may descend into it* and gradually distend the fold so as to form a cruro scrotal hernia. As the hernia progresses the pouch becomes larger and more definite and hangs directly downwards and does not pass backwards into the perineum. On examining a patient who is the subject of this form of hernia it will be first noticed that the scrotum is either imperfectly developed on one side or, being developed, it is not distended. Lying external to it and separated from it by a distinct sulcus is an adventitious sac covered with normal skin. On the patient being requested to cough an expansile impulse will be felt in the swelling. The contents of the sac are usually reducible and after reduction a small testis may usually be felt fixed at the bottom of the pouch of skin which, when the viscera are not distending it, hangs lax and is thrown into folds.

A hernia which accompanies the testis into the tissues of the perineum may be designated a superficial perineal hernia, it being termed superficial to distinguish it from that rare form of perineal hernia which leaves the pelvis through a gap in its floor. The course of the descent of a superficial perineal hernia is from the abdomen, along the canal, through the superficial ring, past the scrotum near its entrance and then backwards towards the margin of the anus. This form of hernia is necessarily rare, for perineal ectopia of the testis is uncommon, and even when present an accompanying hernia is seldom seen. It appears as an elastic swelling on one side of the perineum with an expansile impulse on cough, frequently resonant on percussion, and usually reducible on pressure. After the *return of the contents of the sac the testis, sometimes well* developed, can be felt lying by the side of the anus and often tethered by a band, probably of the gubernaculum, to the region of the external sphincter or tuberosity of the ischium.

# NEUROLOGICAL FRAGMENTS

### LOWEST LEVEL FITS.—HYPOTHESIS ON THE MECHANISM OF LARYNGEAL CRISIS IN TABES DORSALIS.—THE PHYSIOLOGICAL FACTOR IN SYMPTOMATOLOGIES.—REMARKS ON SOME OTHER LOWEST LEVEL FITS.—TERMINAL TONIC SPASMS

A LARYNGEAL crisis is one of what (THE LANCET, Feb 16th 1895 p 394) I called the Sub-maladies of Tabes Dorsalis. It is a respiratory, or a respiratorily beginning, fit; it is a "lowest level fit"—a "bulbar fit." Even a slight laryngeal crisis is a rudimentary respiratory fit. In severe laryngeal crises loss of consciousness and convulsion may occur. Grasset in his important work ("Maladies du Système Nerveux," 4th ed., vol i, p 548, chapter on "Progressive Locomotor Ataxy") writes: "Raymond a bien décrit les divers troubles bulbaires laryngo-bronchiques et notamment ce que Charcot et Cherchewsky ont étudié sous le nom de *vertige laryngé*." The following is by Raymond: "Au moment de la crise le malade éprouve une sensation de strangulation, de chaleur au larynx, suivie d'un véritable spasme de la glotte. Puis le malade perd connaissance; il tombe sur le sol, *il est pris de secousses comme un épileptique* [no italics in original]. Après quoi il se relève, et cette attaque peut se renouveler un certain nombre de fois." The following quotation from Marie's very valuable work, "Lectures on Diseases of the Spinal Cord," New Syd. Soc. (translated by Lubbock), p. 278, gives Charcot's account of the *laryngeal ictus* in tabes: "...... Usually a burning sensation is first felt in the region of the larynx, representing a form of aura, which is followed by a dry cough occurring in short hacks, the patient then falls to the ground in a state of unconsciousness, and most often general flaccidity, whilst epileptiform convulsions sometimes occur, causing the attack at times to resemble those which occur in epilepsy; the face is usually livid."

The convulsions and loss of consciousness result, I suppose, from asphyxia set up by spasm of the muscles closing the glottis and perhaps from spasm of other muscles of the thoracic cage. We must bear in mind that whilst highly supervenous blood annuls the function of convolutions, at least of those of the Rolandic area (motor province of the Middle Level), it strongly stimulates the Respiratory and some other "vital" centres of the Lowest Level.

In a severe laryngeal crisis the glottis is in an extreme expiratory condition; possibly, it is completely closed. In this note I state an hypothesis as to the neuro-muscular mechanism of this spasmodic closure or narrowing. It is an impossibility that this positive, or rather super-positive, thing can be caused, in a strict sense of the word cause,[1] by a negative lesion of any part of the nervous system. Yet in most cases of these crises in tabetics there presumably *is* a negative central lesion, one answering to paralysis of the abductor muscles of the vocal cords (Semon)—a negative lesion of the medulla centres for these muscles, some motor centres of the Lowest Level. I shall in what follows consider cases in which the abductor muscles are paralysed until I come towards the end of this note when cases of tabetic patients subject to laryngeal crises, who have no discoverable paralysis of these muscles, will be spoken of.

The adductor muscles of the vocal cords and, inferentially, their medulla centres, some centres of the lowest level, are, in the cases I now deal with, intact and so, too, is the Respiratory, medulla, centre, a Superior centre of the Lowest Level.[2]

Applying to a particular case a notion from Duchenne as to muscular action in general, I suggest that in normal conditions the abductor and adductor muscles of the vocal cords act in a "coöperation of antagonism" ("in amicable antagonism")—that when the glottis of a healthy man is widened there is *preponderating* action of the abductor muscles with *moderating* action of the adductors, and that when it is narrowed, there is *preponderating* action of the adductor muscles with *moderating* action of the abductors. And correspondingly, that there is simply preponderating activity, as the case may be, of the abductor or of the adductor (medulla) centres.[3]

We must bear well in mind that for respiration proper these two laryngeal motor centres, abductor and adductor (and also phrenic and costal motor centres, other centres of the Lowest Level) are some of the fundamental centres of the Lowest Level and are subordinate to the Respiratory (medulla) centre, one of the Superior centres of the Level. There is no reason to suppose that the abductor and adductor muscles of the vocal cords (similarly for muscles, which for the present I ignore, of other parts of the thoracic cage) ever act *respiratorily* (Organic Duty), except at the instigation of the Respiratory (medulla) centre and by intermediation of the medulla abductor and adductor motor centres for these muscles. I say "act respiratorily" because I suppose (THE LANCET, Feb. 23rd, 1895, p. 476, and THE LANCET, Dec. 16th, 1899, p. 1659) that the laryngeal motor centres (the medulla abductor and adductor centres spoken of) when they serve in an Animal Duty—that is, in "voluntary operations," that is, in operations of cerebral (Higher Level) initiation, for example, preparatory to, and during certain kinds of "effort" (as when lifting a heavy weight with one hand) or in drawing in the breath when told—are acted on (as are also the costal motor centres for movements of another part of the thoracic cage) by intermediation of fibres of the pyramidal tract which on their way down from motor centres of the Middle Level (Rolandic Region) of the cerebral subsystem pass by and, so to say, evade the Respiratory centre. I went further in speculation, suggesting that during these animal services of the thoracic cage the (medulla) Respiratory centre is inhibited by cerebral Higher Levels.[4]

To repeat. In health the Superior, the Respiratory, medulla, centre, my supposition is, puts both the abductor and adductor muscles of the vocal cords in action during inspiration proper (the action of the abductors then preponderating) and does or can put them both in action in expiration (the action of the adductors then preponderating); in each case the Respiratory centre acts on the vocal cords by intermediation of the subordinate abductor and adductor, motor centres.[5]

Besides governing the abductor and adductor motor centres of the medulla region of the lowest level, the Respiratory (medulla) centre—I am still dealing with healthy conditions—governs also those other motor centres of the cervical and dorsal regions of the lowest level which are for the diaphragmatic (phrenic centres) and costal movements (costal centres) of the thoracic cage. Now speaking of tabes abdominal muscles are, no doubt, engaged expiratorily in some stage of severe laryngeal crises. To return to a consideration of the mechanism of these Crises. (What I shall call the Respiratory Nervous System of the Lowest Level is, of course, much more complex than I describe it )

So far I have spoken as if in the case of those tabetic patients who are subject to laryngeal crises the only flaw in the Respiratory Nervous System of the Lowest Level is a *negative* lesion of, or of more or less of, the motor centres for the abductor movements of the vocal cords. Presumably there is something more than this negative lesion; there is also, I submit, an opposite, a super-positive, lesion, a so-called "irritative state," of some sensory medulla elements—a super-positive functional lesion produced by some pathological process.

In those tabetics who are subject to laryngeal crises it is said that there is hyperæsthesia of some part of the mucous membrane of the larynx. This, however, is, I suppose. understood to mean that there is an "irritative state," or as I prefer to say, a super-positive functional state of medull *sensory* nervous elements representing that part.[6] We ar here, it will be seen, assuming that there are sensory medull centres subservient to the Respiratory centre; these ar sensory companions of the motor abductor and adducto centres which are subordinate to the Respiratory centre. I healthy people the respiratory centre is, or can be, acted o *upwardly* from the mucous membrane of the larynx by inter mediation of these subservient sensory centres; and th muscles of the vocal cords are acted on *downwardly* by th of the contents of a hernial sac through the superficial abdominal ring. Repeated expiratory efforts drive the viscera into a patent processus vaginalis, and after a time tend to force the testis and the viscera from the canal through the superficial ring. The gland is, however, prevented from being extruded by its short cord and the peritoneal pouch dilates in the plane of least resistance, but, on the other hand, the smallness of the superficial ring itself may be the cause of the imprisonment both of the testis and of the contents of the sac. Secondly, want of muscular development in the inguinal region is not infrequently present with a want of descent of the testis, and may be a reason why the hernial sac insinuates itself in the planes of the abdominal wall, though it is open to question whether the abnormal condition of the muscles is not rather the result of the pressure exerted by the hernial protrusion than the cause of the formation of the sac. Thirdly, it is possible that some abnormal drag of the gubernaculum testis on a portion of the peritoneum near the abdominal opening of the processus vaginalis may cause adventitious pouches to be formed and these lead to the production of an interstitial sac.

---

[2] See THE LANCET, Feb 23rd, 1895, p 476, on Superior and Subordinate Centres of the Lowest Level.

[3] Possibly what we call the abductor medulla centre simply represents movements of the abductor muscles much more than it does movements of the adductors; similarly, *mutatis mutandis*, for the adductor centre.

[4] I here refer the reader to a case of supposed pneumonia recorde (No. XII., THE LANCET, Dec. 22nd, 1894, p 1472), in which with loss o the respiratory movements of the intercostal muscles, perfect "volun tary" (cerebral) movement of these same muscles remained possibl The knee jerks were absent.

[5] The term centre, as here applied in the expressions "abducto centre" and "adductor centre" and on other occasions, is not use rigidly Horsley and Semon (Phil. Trans., vol. 181 (1890), pp. 187–21 have, however, found that experimental excitation of two differen particular parts of the medulla oblongata produces, of one, adductio of the other abduction of the vocal cords." (In beginning the investigations on this matter Semon and Horsley found abductio alone to be represented in the medulla oblongata).

I may here mention that Risien Russell has found that movement both of the adductors and of the abductors of the vocal cords a represented in the cortex cerebri of the dog. The former (adductio are represented in the præcrucial gyrus, just where it terminates i the narrow isthmus which connects it with the anterior composit gyrus, as had been previously found by Krause and by Horsley an Semon. The latter (abduction) is represented in the anterior com posite gyrus just behind the supra-orbital sulcus and below the level the imaginary prolongation of the coronal sulcus, to touch the supr orbital sulcus. "The Influence of the Cerebral Cortex on the Laryn Phil. Trans., vol. 187 (1876) B. pp. 59–81.

[6] That there are so called "irritative" states of some centr elements of the lowest level in many tabetic patients is clear; I ref to "lightning pains"; these pains (super-positive things) cannot owing to a negative state (sclerosis, loss of function and structur destruction, of fibres), but must be owing to an exactly opposi functional state of some central nervous elements, I suppose to a s called "irritative" condition of cells of sensory centres of the cor In "Neurological Fragments" (THE LANCET, March 5th, 1892, p. 51 I spoke, quoting Semon, of an "irritative state" of the adduct centres in laryngeal crises. I now suppose, as I have said in the tex that these motor centres are healthy and that their over-action these crises is brought about in a very indirect way.

There are three chief varieties of interstitial hernia usually described In the first the sac is found between the aponeurosis of the external oblique and the muscular fibres of the internal oblique and this is the one which is most frequently associated with arrest of the testis. It usually presents an external swelling which is very characteristic in its shape and extent; beginning in the region of the inguinal canal, it mounts upwards and outwards towards the anterior superior spine of the ilium The whole course of the gradual formation of the tumour can be observed if a patient, after the contents of the sac have been reduced, is directed to lie on his back and cough There is no other condition that will give the spectacle of a gradually increasing tumour under these circumstances. The shape of the swelling is usually ovoid and its margins are fairly distinct. It is flattened on the surface and does not project far from the abdominal wall. The limits of the tumour may be wide and sometimes it reaches as high as the costal arch, sometimes it may overlap the rectus muscles or may even hang down in front of Poupart's ligament so as to simulate a femoral hernia The contents of the sac can generally be reduced, though sometimes it is a difficult matter entirely to empty it. When reduction has been effected, the ill-developed testis can be made out *lying in the inguinal* canal. When there is a scrotal portion as well as an interstitial, the former is usually secondary to the development of the latter and usually indicates that the resistance to the increase in the primary part has become greater than that to the entry of the viscera into the scrotum. The second variety of interstitial hernia is that in which the sac is placed between the aponeurosis of the external oblique and the skin. It also is not infrequently associated with an arrest of the testis. The method in which the sac has arrived at its position may be one of two. Either the peritoneum has been pushed forward and then upward through a gap in the aponeurosis, or the sac, at first lying in the inguinal canal, *has transgressed the* bounds of this *space, protruded* through the superficial ring, and finding its way into the scrotum blocked has turned upward on the abdominal wall. In both of these the direction taken by the hernia is that of the least resistance, for the attachment of the deep layer of the superficial fascia to the front of Poupart's ligament would bar its progress into the thigh. As a rule, the external swelling present in the second variety is more pronounced than that of the first. Some help may be obtained in the diagnosis between the two forms by requesting the recumbent sufferer to raise his head and shoulders, and thus throw into action the abdominal muscles, when if the external oblique is placed in front of the sac the hernia will become more tense, but will not evidently increase much, while if the aponeurosis be posterior to the bulk of the swelling then this will be markedly enlarged and its tenseness will only be augmented in proportion to its size The third form of interstitial hernia is that in which the sac lies in the plane between the transversalis fascia and the peritoneum, that is, in the extra-peritoneal tissue. This is a rare form and one which is not so commonly associated with imperfect descent of the testis. There is usually a scrotal portion of the sac in addition to the properitoneal. In almost every case the additional portion of the sac within the abdominal wall has not been recognised until after death or during an operation on account of the strangulation, for there is no external swelling and it is rare that the deeper part of the sac can be palpated. There are two chief sites in which the secondary sac may be placed, one the iliac fossa and the other the prevesical region.

By a cruro-scrotal hernia is meant a hernial sac which distends not the scrotal tissues but the fold of skin which is found between the scrotum and the thigh. The hernia, therefore, will be covered with ordinary cutaneous tissue and not with dartos It is always associated with an imperfect or abnormal descent of the testis, and the hernia follows the organ. The testis, usually an imperfectly developed one, having left the inguinal canal, is for some reason—probably either a want of development of the scrotal tissue or a tenseness of the fascia at the entrance of the scrotum—prevented from continuing its further descent into that region. It will therefore remain permanently in the cruro-scrotal fold, or pass into the perineum or possibly into Scarpa's triangle. If the processus vaginalis testis which accompanies it remains patent viscera may descend into it and gradually distend the fold so as to form a cruro-scrotal hernia. As the hernia progresses the pouch becomes larger and more definite, and hangs directly downwards and does not pass backwards into the perineum. On examining a patient who is the subject of this form of hernia it will be first noticed that the scrotum is either imperfectly developed on one side or, being developed, it is not distended. Lying external to it and separated from it by a distinct sulcus is an adventitious sac covered with normal skin. On the patient being requested to cough an expansile impulse will be felt in the swelling. The contents of the sac are usually reducible and after reduction a small testis may usually be felt fixed at the bottom of the pouch of skin which, when the viscera are not distending it, hangs lax and is thrown into folds.

A hernia which accompanies the testis into the tissues of the perineum may be designated a superficial perineal hernia, it being termed superficial to distinguish it from that rare form of perineal hernia which leaves the pelvis through a gap in its floor. The course of the descent of a superficial perineal hernia is from the abdomen, along the canal, through the superficial ring, past the scrotum near its entrance, and then backwards towards the margin of the anus. This form of hernia is necessarily rare, for perineal ectopia of the testis is uncommon, and even when present an accompanying hernia is seldom seen. It appears as an *elastic swelling on one side of the perineum with an* expansile impulse on cough, frequently resonant on percussion, and usually reducible on pressure. After the return of the contents of the sac the testis, sometimes well developed, can be felt lying by the side of the anus and often tethered by a band, probably of the gubernaculum, to the region of the external sphincter or tuberosity of the ischium.

### LOWEST LEVEL FITS.—HYPOTHESIS ON THE MECHANISM OF LARYNGEAL CRISIS IN TABES DORSALIS.—THE PHYSIOLOGICAL FACTOR IN SYMPTOMATOLOGIES.—REMARKS ON SOME OTHER LOWEST LEVEL FITS.—TERMINAL TONIC SPASMS.

A LARYNGEAL crisis is one of what (THE LANCET, Feb. 16th, 1895, p. 394) I called the Sub-maladies of Tabes Dorsalis. It is a respiratory, or a respiratorily beginning, fit; it is a "Lowest Level fit," a "bulbar fit." Even a slight laryngeal crisis is a rudimentary respiratory fit In severe laryngeal crises loss of consciousness and convulsion may occur. Grasset in his important work ("Maladies du Système Nerveux," 4th ed., vol. I., p. 548, chapter on "Progressive Locomotor Ataxy") writes: "Raymond a bien décrit les divers troubles bulbaires laryngo-bronchiques, et notamment ce que Charcot et Cherchewsky ont étudié sous le nom de *vertige laryngé.*" The following is by Raymond: "Au moment de la crise, le malade éprouve

The loss of consciousness may be partly owing to upward discharges from the Respiratory centre to the cerebral cortex (Binswanger and Horsley) or to super-venosity, or to both.

It may be said that if the mechanism of a severe laryngeal crisis be as stated, if the asphyxia started by closure of the glottis is increased in compound degree to a maximum by increasing stimulation of the respiratory centre by blood getting more and more super-venous, the patient must die in his attack. But, as I mentioned in a former paper (THE LANCET, March 5th, 1892, p. 509), Risien Russell has found[10] that a dog has gone through all stages of artificially produced asphyxia (convulsion, of course, in one of the stages), and yet, on removal of the tracheal clamp, has recovered without artificial respiration.

Mr. Victor Horsley was so good as to make for me some experiments and observations on the condition of the vocal cords during artificially produced asphyxia. (The animals were etherised.) It is of importance with regard to the asphyxia occurring in severe laryngeal crises to know what goes on in the larynx in the asphyxia of otherwise healthy animals in which abductor as well as adductor movements of the cords are possible. The following is the substance of an account written for me by Mr. Horsley.

A cat etherised was tracheotomised; a window was made in the trachea so that the larynx could be viewed from below. At 11.30 A.M. the vocal cords were moving strongly and synchronously with the chest. When the trachea was clamped;—

(A) At the commencement of Inspiration (i.e., abduction);—the cords abduct and remain abducted for about two seconds, and then move synchronously with the movements of the chest which follow and persist during the asphyxial state until towards the end when the cords stop with the chest;—

(B) At the commencement of Expiration (i.e., adduction);—the cords adduct firmly and remain adducted for about four seconds and then move synchronously with the chest as in (A).

If the asphyxial state be kept up until respiration stops and if after that artificial respiration be begun, the following is observed: (*a*) With the *first* insufflation of the chest there occurs an inspiratory movement of the vocal cords (i.e., abduction). (*b*) Next succeed a few irregular movements of the cords partly synchronous with the chest movements which begin to recover and accelerate spontaneously even before the artificial insufflation of the chest is stopped. (*c*) The artificial respiration being stopped it is found that the chest moves rapidly (100 per minute) but that the cords are in strong abduction[11] and remain so. (*d*) Gradually as the effect of the asphyxia passes off the cords begin to move, but very slowly, the abductions being prolonged over the period of two movements of the chest. Consequently the rhythm of larynx to chest is one to three and therefore asynchronous. (*e*) Gradually after about a quarter of an hour normal synchronism is restored.

Mr. Horsley observed the same in a dog except that the abduction arrest of the laryngeal movements was only slightly marked.

In the animals experimented on the abductor muscles and their centres were intact and thus there was inspiratory activity of the vocal cords in asphyxia, a thing impossible in the asphyxia of a tabetic with paralysis of the abductors.

To return to Laryngeal Crises in tabetics. I do not conclude that the internal muscles of the larynx alone are concerned even in the first stage of the severe attacks we call *laryngeal* crises; experimental excitation of the superior laryngeal nerve in a lower vertebrate brings the abdominal muscles into expiratory action. Here is an important matter with regard to operative procedures in tabetic patients subject to severe laryngeal crises. Tracheotomy would obviate the effects of spasm of the adductors of the glottis in a laryngeal crisis, but could not prevent over-activity of other expiratory muscles—those of the abdominal wall, for example. The following quotation from the late Dr. Althaus' work, "Sclerosis of the Spinal Cord," p. 188, is interesting in this regard. In the case of severe laryngeal crises which he mentioned great benefit was derived from tracheotomy, but less severe crises occurred after the operation. Speaking of the severest of three degrees of laryngeal crises, Dr. Althaus wrote (I italicise some words): "The patient may die in the fit, the heart's action being likewise presently arrested. Krishaber has in such a case performed tracheotomy, and thereby probably saved the life of the patient. After the operation the crises became subdued, the laryngeal spasm being much less severe. The patient no longer lost his consciousness in such *fits and seemed to have rather more spasm in the diaphragm than in the larynx.* This man wore a canula for some years afterwards and when he felt an attack coming on, opened it at once in order to allow air to enter the windpipe."[12]

The neuro-muscular mechanism of a laryngeal crisis is supposed to illustrate the same general principle as does that of production of "secondary deviation" of the left eye in the case of paralysis of the external rectus of the right eye, when the patient tries to look far to the right. (I suppose that the lesion is of the trunk of the right sixth nerve.) In both cases there is over-development ("forcing") of one movement consequent on a strong, but yet abortive, attempt to develop an associated movement. There are, however, important differences in the application of the principle to the two cases, that is on the supposition that my hypothesis of the mechanism of a laryngeal crisis is correct. In ocular paralysis there is a negative lesion only, and the "forced movement" (the secondary deviation of the sound eye) is of cerebral (higher level) initiation—is, to speak popularly, the result of strong "volition." In the laryngeal crises of tabes (in which the lowest level alone, not the higher levels is concerned), there is a sensory super-positive lesion (medulla) which when roused into activity from the periphery (laryngeal mucous membrane) next induces very strong activity of the healthy respiratory (medulla) centre. So much for the upward activity. It is with the downward activity from the respiratory centre that there comes the similarity with the production of secondary deviation of the normal eye in the case of ocular paralysis. To speak figuratively, any efforts there could be for the initial narrowing or closure of the glottis by the greatly over-acting respiratory centre in the asphyxial stage (if there be in healthy people the coöperation of antagonism Duchenne supposed) to produce abduction, would be abortive and would necessarily produce very great adduction; this is just as a strong effort (the impulses in this case starting from higher levels) to turn out, abduct, the lamed right eye (in a case of lesion of one sixth nerve to the external rectus of that eye) are abortive and necessarily produce very great turning in (adduction) of the sound left eye.

The same general principle—that the positive or super-positive parts of symptomatologies in cases with negative lesions are owing to action or to over-action of perfectly healthy nervous elements—that these parts of symptomatologies are in the domain of physiology and not of pathology—has been exemplified (THE LANCET, Dec. 12th, 1896, p. 1662) by the case of thigh lifting when there is paralysis of the extensors of the feet, and, very hypothetically, by writer's cramp (and implicitly by other occupation neuroses). In the fifth paragraph, *op. cit.*, the same principle is illustrated by what I suppose to be the mechanism of the ataxic gait (underdoing of some movements and overdoing (forcing) of others). I should apply the hypothesis[13] to the other crises of tabes.

---

regarderait en même temps le tronc d'un chien décapité et le tronc d'un chien asphyxie, aurait peine à reconnaître une différence entre les deux à déterminer le genre de mort auquel, l'un et l'autre animal ont succombé. C'est que les mouvements, identiques dans les deux cas, sont dus à la même cause, à l'asphyxie: après la décapitation, le tronc, comme la tête, meurt asphyxié." "La Mort par la Decapitation," par le Dr Paul Loye, p. 116.

[10] Risien Russell has published his researches on this subject, Proc. Roy. Soc., vol. liii, p. 430.

[11] During this persisting abduction Mr. Horsley observed that a swallowing movement of the pharynx was accompanied by the usual closure of the glottis, normal in strength and extent.

[12] In the Medical Times and Gazette, Dec. 15th, 1866, I recorded what I now believe to have been a case of tabes with a laryngeal crisis. I did not then, 35 years ago, make even the diagnosis of tabes. The case is, however, valuable on account of a laryngoscopical examination by the late Sir Morell Mackenzie. Sir Morell Mackenzie diagnosed "paralysis of crico arytenoidei postici dependent on disease within the cranium." The larynx was examined post mortem by the late Mr. Rivington, and atrophy of these muscles was found. No doubt there was disease in the medulla, but no microscopical examination of it was made. I regret that I did not adopt Sir Morell Mackenzie's advice and direct tracheotomy to be done earlier. Laryngo tracheotomy was done, but too late to save the patient.

[13] The word "hypothesis" is hardly used; it is sometimes used as if it meant conclusion, a most erroneous use of it, and sometimes for mere conjecture. I am using it in the text in the sense that when I have opportunities for observation I shall attempt so to analyse the symptomatology of gastric and other crises that I may ascertain whether, to speak very generally, there *is* or *is not* underdoing of one movement, or of some movements, with *necessitated* forcing of another or of some others.

Respiratory centre by intermediation of the subordinate motor, abductor and adductor, centres. In laryngeal crises the action *upwardly* on the Respiratory centre is supposed to be far greater than in health, because those sensory centres, which are on the upward path from the mucous membrane of the larynx to the Respiratory centre, are in an "irritative" condition and are thus intensifiers. And in those cases there are no longer abductor centres to be influenced by the greatly increased downward action of the respiratory centre.

I stay here to remark that, in scientific exposition, I do not use the word "functional" in senses in which it is used clinically by many medical neurologists—as it is used, for example, when it is said of a patient "that all his symptoms are functional." I use it as the adjective of the word function. The function of nervous matter is to "store up" and to "expend" energy (anabolism and katabolism) Hence I use the term function for the dynamics, the physiology, of the nervous system. In what I call a Negative Lesion there is defect or loss of function, defective or lost expenditure of energy—a crude hypo-physiological state; or if the negative lesion be a destruction-lesion, there is loss of function and of structure too—there is a structural and functional vacuum. In a super-positive lesion there is excess of function; there is an increased expenditure of energy—a crude hyper-physiological state (The separation into structure, function and nutrition is, of course, artificial.) I venture to think that there is no such thing as a functional lesion without a corresponding alteration of nutrition or of structure or of both. But then I must say that I only apply the terms negative and super-positive *lesions* to those functional states which are *produced by pathological processes or by injury.* In a patient subject to laryngeal crises, according to the hypothesis stated, there are two opposite functional *lesions;* a negative one (loss of function and of structure too) of the abductor centres and a super-positive one, a so-called "irritative lesion," of sensory laryngeal centres; these lesions, negative and super-positive, are produced by pathological processes. And although the Respiratory centre and the adductor centres are engaged in the crises, these are healthy centres which are compelled *ab extra* to function excessively (hyper-physiologically); they are not the subjects of any pathological process and thus there is not what I should call a *lesion* of either. I speak so far of the first stage of the crises; in the second stage when asphyxia comes on, we may say that these centres are in a pathological state from great super-venosity, there is whilst that super-venosity lasts a change in their metabolism which makes them more explosive. (Of course in increased function of healthy nervous elements there will be correspondingly greater metabolism than in their normal activity.)

To return to the crises, with some recapitulation. The hypothesis is that there are in most of those tabetic patients who are subject to laryngeal crises, two persisting abnormal functional lesions—not only a persistent *negative* functional (in this case a complete structural, a destruction) lesion of motor elements (of the subordinate abductor centres), but also a persistent *super-positive* functional, so-called "irritative," lesion of sensory elements (of the subservient sensory centres) The two opposite functional lesions are supposed to be the only lesions, *the only things, I mean, which are produced by pathological processes;* the remainder of "the respiratory nervous system of the lowest level" is supposed to be healthy—to be untouched by any pathological process And yet this healthy remainder, or much of it (the adductor centres and the Superior, the medulla, Respiratory, centre) is strongly engaged in the crises That the centres of the healthy remainder are really healthy is shown in most cases by the facts that the tabetic patient with persisting paralysis of the abductors of his vocal cords, breathes ordinarily, I mean in the intervals of laryngeal crises, without particular difficulty or discomfort, and that his voice during talking is but little affected Yet now and then a laryngeal crisis, a lowest level fit, occurs and the patient may be cyanosed in it by compulsory engagement of these healthy, these innocent, centres.

Now for the hypothesis as to the mechanism of the paroxysm itself. An impulse from a part of the interior of the larynx (the "epileptogenous," or better, the "peripheral," zone) puts the medulla sensory centres representing that part into great activity, they being, from their "irritative" state[7] very susceptible. These *morbid* sensory centres, easily roused into great over-activity, provoke great over-activity of the *healthy* Respiratory centre. Consequently, from this *healthy* Superior Respiratory centre *abnormally* strong impulses come down to *both* (that is on the principle of coöperation of antagonism) the subordinate abductor centres (or properly speaking to the place where these abductor centres once were) and to the subordinate adductor (healthy) centres; the impulses will be especially to the adductor centres, the nisus[8] being for expiration. The impulses coming down from the healthy respiratory (medulla) centre being in the circumstances abnormally strong, there is induced by them abnormally great over-activity of the healthy adductor centres and consequent excessive development of the adductor movements of the vocal cords; moreover, these movements are no longer restrained, because the abductor movements cannot be developed to act in "amicable antagonism" to fight against, the strong adduction. The glottis is very much narrowed, possibly closed. So much for what we call the first stage of the crisis; it may be the sole stage. We shall next consider the *effect* of this induced adductor spasm of the glottis (and possibly also embarrassment or fixation of the chest walls, *vide infra*)—that is the asphyxia; we might call this, the second stage of a severe laryngeal crisis.

As the blood becomes rapidly very super-venous consequent on the narrowing or closure of the glottis, the Respiratory medulla centre will be still more strongly stimulated but in a different way from that stated so far—it will be stimulated by the super-venous blood. In consequence its over-action, its discharge, will become still greater than it was from stimulation by impulses from the interior of the larynx by way of the subservient sensory centres. Thus the Respiratory (medulla) centre will (still, of course, by intermediation of the subordinate adductor centres) make the vocal cords come still closer, or more tightly, together and will keep up the closure of the glottis. For if in those whose respiratory nervous system of the lowest level is *intact*, abnormally strong discharges of the Respiratory (medulla) centre caused by super-venous blood in asphyxia produce, or constitute one factor in the production of, inspiratory, abductor, movements of the vocal cords first of all, they cannot in the crises we are considering produce these movements at all because the abductor muscles are paralysed from negative lesion of their medulla centres. Moreover (see footnote on effects of experimental excitation of the superior laryngeal nerve in some lower animals) the respiratory centre in a laryngeal crisis is, so to say, "tuned for expiration" by the impulses starting from the laryngeal mucous membrane. The asphyxia will increase in compound degree; for the more the thoracic cage is fixed the more venous does the blood become and thus the greater is the stimulation of the Respiratory centre and therefrom still more persistent is the fixation of the thoracic cage.

The convulsion which sometimes occurs in severe laryngeal crises is presumably owing to abnormally strong discharges of the Respiratory centre set up by super-venous blood; crises of this degree are severe asphyxia fits. Doubtless there are, besides discharges of motor centres for movements of the thoracic cage, discharges of other fundamental motor centres of the lowest level produced by the discharges beginning in the Respiratory centre. Possibly, however, discharges of some of these fundamental motor centres of the lowest level are directly induced by super-venous blood. In this, the second, stage of laryngeal crises there is evidently a Respiratory, an asphyxia, a Lowest Level, a bulbar, fit.[9]

---

[7] "Charcot and Krishaber have shown that the (laryngeal) crises (in tabes) are due to reflex contracture of the muscles adjoining the glottis, a contracture which is due to hyperæsthesia of the mucous membrane (of the larynx), these authors having been able to reproduce it by touching that mucous membrane with a soft body" (Marie's Lectures on Diseases of the Spinal Cord, New Syd. Soc. Trans., by Lubbock, p. 279).

[8] I say the nisus for expiration, because experimental excitation of the central end of the superior laryngeal nerve (which nerve supplies the mucous membrane of the larynx sensorily) produces inhibition of inspiration and stimulates expiration. "The superior laryngeal nerve is remarkable for containing a large number of inhibitory respiratory nerves, or nerves which cause arrest of the respiration in expiration, or even fibres causing expiration. One knows that it is the sensory nerve of the larynx, and that foreign bodies or irritating matter in the larynx excites coughing, i.e., forced expiratory acts reflexly." (Physiology, by Landois and Stirling, ed. 4, vol. ii., p. 871.) And if the nisus in a laryngeal crisis were for inspiration, the glottis would not dilate, the abductor muscles being paralysed; I suppose on the contrary, if the principle of "coöperation of antagonism" applies, the great excitation on a strong nisus for inspiration must produce closure.

[9] According to what is said in the following quotation there is certainly producible in a dog a lowest level fit (or rather, so to say, part of one) from asphyxia independently of the higher levels and of the higher parts of the lowest level. "Ainsi, un observateur, qui

The loss of consciousness may be partly owing to upward discharges from the Respiratory centre to the cerebral cortex (Binswanger and Horsley) or to super-venosity, or to both.

It may be said that if the mechanism of a severe laryngeal crisis be as stated, if the asphyxia started by closure of the glottis is increased in compound degree to a maximum by *increasing stimulation of the respiratory centre* by blood getting more and more super-venous, the patient must die in his attack. But, *as I mentioned in a former paper* (THE LANCET, March 5th, 1892, p. 509), Risien Russell has found[10] that a dog has gone through all stages of artificially produced asphyxia (convulsion, of course, in one of the stages), and yet, on removal of the tracheal clamp, has recovered without artificial respiration.

Mr. Victor Horsley was so good as to make for me some experiments and observations on the condition of the vocal cords during artificially produced asphyxia. (The animals were etherised.) It is of importance with regard to the asphyxia occurring in severe laryngeal crises to know what goes on in the larynx in the asphyxia of otherwise healthy animals in which abductor as well as adductor movements of the cords are possible. The following is the substance of an account written for me by Mr. Horsley.

A cat etherised was tracheotomised; a window was made in the trachea so that the larynx could be viewed from below. At 11 30 A.M. the vocal cords were moving strongly and synchronously with the chest. When the trachea was clamped ;—

(A) At the commencement of Inspiration (i.e., abduction) ;—the cords abduct and remain abducted for about two seconds, and then move synchronously with the movements of the chest which follow and persist during the asphyxial state until towards the end when the cords stop with the chest ;—

(B) At the commencement of Expiration (i.e., adduction) ;—the cords adduct firmly and remain adducted for about four seconds and then move synchronously with the chest as in (A).

If the asphyxial state be kept up until respiration stops and if after that artificial respiration be begun, the following is observed : (*a*) With the *first* insufflation of the chest there occurs an inspiratory movement of the vocal cords (i.e., abduction). (*b*) Next succeed a few irregular movements of the cords partly synchronous with the chest movements which begin to recover and accelerate spontaneously even before the artificial insufflation of the chest is stopped. (*c*) The artificial respiration being stopped it is found that the chest moves rapidly (100 per minute) but that the cords are in strong abduction[11] and remain so. (*d*) Gradually as the effect of the asphyxia passes off the cords begin to move, but very slowly, the abductions being prolonged over the period of two movements of the chest. Consequently the rhythm of larynx to chest is one to three and therefore asynchronous. (*e*) Gradually after about a quarter of an hour normal synchronism is restored.

Mr. Horsley observed the same in a dog except that the abduction arrest of the laryngeal movements was only slightly marked.

In the animals experimented on the abductor muscles and their centres were intact and thus there was inspiratory activity of the vocal cords in asphyxia, a thing impossible in the asphyxia of a tabetic with paralysis of the abductors.

To return to Laryngeal Crises in tabetics. I do not conclude that the internal muscles of the larynx alone are concerned even in the first stage of the severe attacks we call *laryngeal* crises ; experimental excitation of the superior laryngeal nerve in a lower vertebrate brings the abdominal muscles into expiratory action. Here is an important matter with regard to operative procedures in tabetic patients subject to severe laryngeal crises. Tracheotomy would obviate the effects of spasm of the adductors of the glottis in a laryngeal crisis, but could not prevent over-activity of other expiratory muscles—those of the abdominal wall, for example. The following quotation from the late Dr. Althaus' work, "Sclerosis of the Spinal Cord," p. 188, is interesting in this regard. In the case of severe laryngeal crises which he mentioned great benefit was derived from tracheotomy, but less severe crises occurred after the operation. Speaking of the severest of three degrees of laryngeal crises, Dr. Althaus wrote (I italicise some words) : "The patient may die in the fit, the heart's action being likewise presently arrested. *Krishaber has in such a case performed tracheotomy, and* thereby probably saved the life of the patient. After the operation the crises became subdued, the laryngeal spasm being much less severe. The patient no longer lost his consciousness in such *fits and seemed to have rather more spasm in the diaphragm than in the larynx.* This man wore a canula for some years afterwards and when he felt an attack coming on, opened it at once in order to allow air to enter the windpipe."[12]

The neuro-muscular mechanism of a laryngeal crisis is supposed to illustrate the same general principle as does that of production of "*secondary deviation*" of the left eye in the case of paralysis of the external rectus of the right eye, when the patient tries to look far to the right. (I suppose that the lesion is of the trunk of the right sixth nerve.) In both cases there is over-development ("forcing") of one movement consequent on a strong, but yet abortive, attempt to develop an associated movement. There are, however, important differences in the application of the principle to the two cases, that is on the supposition that my hypothesis of the mechanism of a laryngeal crisis is correct. In ocular paralysis there is a negative lesion only, and the "forced movement" (the secondary deviation of the sound eye) is of cerebral (higher level) initiation—is, to speak popularly, the result of strong "volition." In the laryngeal crises of tabes (in which the lowest level alone, not the higher levels, is concerned), there is a sensory super-positive lesion (medulla) which when roused into activity from the periphery (laryngeal mucous membrane) next induces very strong activity of the healthy respiratory (medulla) centre. So much for the upward activity. It is with the downward activity from the respiratory centre that there comes the similarity with the production of secondary deviation of the normal eye in the case of ocular paralysis. To speak figuratively, any efforts there could be for the initial narrowing or closure of the glottis by the greatly over-acting respiratory centre in the asphyxial stage (if there be in healthy people the coöperation of antagonism Duchenne supposed) to produce abduction, would be abortive and would necessarily produce very great adduction ; this is just as a strong effort (the impulses in this case starting from higher levels) to turn out, abduct, the lamed right eye (in a case of lesion of one sixth nerve to the external rectus of that eye) are abortive and necessarily produce very great turning in (adduction) of the sound left eye.

The same general principle—that the positive or super-positive parts of symptomatologies in cases with negative lesions are owing to action or to over-action of perfectly healthy nervous elements—that these parts of symptomatologies are in the domain of physiology and not of pathology—has been exemplified (THE LANCET, Dec. 12th, 1896, p. 1662) by the case of thigh lifting when there is paralysis of the extensors of the feet, and, very hypothetically, by writer's cramp (and implicitly by other occupation neuroses). In the fifth paragraph, *op. cit.*, the same principle is illustrated by what I suppose to be the mechanism of the ataxic gait (under-doing of some movements and overdoing (forcing) of others). I should apply the hypothesis[13] to the other crises of tabes.

---

regarderait en même temps le tronc d'un chien décapité et le tronc d'un chien asphyxié, aurait peine à reconnaître une différence entre les deux, à déterminer le genre de mort auquel, l'un et l'autre animal ont succombé. C'est que les mouvements, identiques dans les deux cas, sont dus à la même cause, à l'asphyxie : après la décapitation, le tronc, comme la tête, meurt asphyxié." "La Mort par la Décapitation," par le Dr Paul Loye, p. 116.

[10] Risien Russell has published his researches on this subject, Proc. Roy. Soc., vol. liii., p. 430

[11] During this persisting abduction Mr. Horsley observed that a swallowing movement of the pharynx was accompanied by the usual closure of the glottis, normal in strength and extent.

[12] In the Medical Times and Gazette, Dec. 15th, 1866, I recorded what I now believe to have been a case of tabes with a laryngeal crisis. I did not then, 35 years ago, make even the diagnosis of tabes. The case is, however, valuable on account of a laryngoscopical examination by the late Sir Morell Mackenzie. Sir Morell Mackenzie diagnosed "paralysis of crico arytenoidei postici dependent on disease within the cranium." The larynx was examined post mortem by the late Mr. Rivington, and atrophy of these muscles was found. No doubt there was disease in the medulla, but no microscopical examination of it was made I regret that I did not adopt Sir Morell Mackenzie's advice and direct tracheotomy to be done earlier. Laryngo-tracheotomy was done, but too late to save the patient.

[13] The word "hypothesis" is hardly used ; it is sometimes used as if it meant conclusion, a most erroneous use of it, and sometimes for mere conjecture. I am using it in the text in the sense that when I have opportunities for observation I shall attempt so to analyse the symptomatology of gastric and other crises that I may ascertain whether, to speak very generally, there *is* or *is not* underdoing of one movement, or of some movements, with *necessitated* forcing of another or of some others.

The same general principle applies, I think, to all cases of insanity except total dementia and to cases of partial aphasia.

I have not forgotten that laryngeal crises occur in some tabetic patients who have no discoverable paralysis of the abductor muscles of the vocal cords (Semon); to these[14] the foregoing hypothesis does not, it may well be said, apply. But there may in them be the "irritative" state of the sensory, medulla, elements suggested. And once more I urge, having regard to the effects of experimental stimulation of the superior laryngeal nerve, that the nisus of the Respiratory centre when it is stimulated from the "irritative" sensory elements representing the laryngeal mucous membrane, is for expiration, for narrowing of the glottis. I suggest that in the cases where the abductor muscles are not discoverably paralysed the "irritative state" of the medulla sensory elements representing part of the mucous membrane of the larynx is very great.

I will now mention some things which I think ought to be considered when we witness a laryngeal crisis of a tabetic. The limbs are, it is said, convulsed in some severe attacks. But perhaps in some of these attacks there occur only writhings of the limbs as an indirect consequence of arrest of respiration; these writhings, being movements proper, ought not to be confounded with convulsion proper, as I believe is done in accounts of some slight cerebral paroxysms commonly called epileptic. If the limbs were the subject of such an intense discharge as produces convulsion there could not be movements even so little elaborate as those of writhing: there would be tonic or clonic spasm of them and not movements properly so-called. In any case of fits, epileptic or of any other sort, we ought to note the condition of the chest and *whether or not the fit begins thoracically*—begins by fixation of the chest walls or by mere cessation of respiration—with subsequent involvement of the limbs.

I here state the hypothesis regarding patients rendered hemiplegic in infancy by a *cerebral* lesion and who later in life become subject to fits, that in some of the cases the fits are *not cerebral* but bulbar (lowest level fits). Certainly very careful attention should be given to the paroxysms in this clinical group of "epilepsies" to determine whether the *onset* is thoracic, more generally by convulsion of the bilaterally acting muscles (trunk) or by convulsion of the limbs. (So, too, for observations of fits in cases of general paralysis.)

I think it possible—this is merely a speculative inference from reports of friends of patients—that there may occur in some stage of a laryngeal crisis terminal tonic spasms like those of tetany. Such terminal tonic spasms are certainly, in no kind of malady, parts of convulsion proper.[15] We should note whether or not the patient perspires very much during the crisis (supervenosity would account for sweating). If he be deeply asphyxiated, we should note whether his knee-jerks are present or absent (no doubt, however, in nearly every case they will be absent at all times, as part of the tabetic symptomatology). Is there passage of urine or fæces in or just after severe seizures? The passage of fæces might be a result of great venosity and thus not a part of the fit proper, or at least a very indirect result of the nervous discharges in the fit.

In some cases of whooping-cough there occur convulsions which are, I suppose, caused by highly supervenous blood (consequent on severe cough-paroxysms) over-stimulating the respiratory centre. Whether, when in these cases there is considerable supervenosity but no convulsion, there are ever carpo-pedal contractions, I do not know. I believe that these persisting terminal tonic spasms are owing, indirectly, to suspension of the influence of certain cells of the Rolandic cortex, and that when they occur in rickety children in association with, in the intervals of, attacks of laryngismus stridulus, and in some other cases, the cerebral influence is suspended owing to supervenosity annulling the function of small cells of the hand area of the Rolandic cortex. The spasm itself is owing *directly* to permitted over-action of cells of anterior horns for the hands and, as I think, also by non-antagonised cerebellar influence upon those horns, cerebral influence on them being suspended.[16] The *attacks* of laryngismus stridulus in rickety infants are, I have tried to show (*Brain*, April, 1886), lowest level fits caused by very great stimulation of the Respiratory centre by supervenous blood.

# SOME REMARKS UPON "INTERNAL DERANGEMENT" OF THE KNEE-JOINT:

## BASED UPON 59 CASES IN WHICH OPERATION WAS PERFORMED.

BY HERBERT W. ALLINGHAM, F.R.C.S. ENG.,
SURGEON IN-ORDINARY TO H.R.H. THE PRINCE OF WALES; SURGEON TO THE HOUSEHOLD OF HIS MAJESTY THE KING; ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL.

"INTERNAL derangement of the knee-joint" is a term that was used originally to describe cases having a well-defined series of symptoms, in which the lesion was held to be always damage or displacement of one of the semilunar cartilages. Since the publication of my book on this subject in 1889 I have met with a variety of cases in point which it may now be of use to put forward. We know now that the trouble within the joint is by no means always of the nature mentioned above.

*Variety of lesion.*—The fact is that a considerable variety of lesions in the knee-joint may all cause the symptoms common to cases known as examples of internal derangement. Moreover, some cases present these symptoms and improve after the joint is opened, although no lesion at all is discerned. This seems just analogous to what happens in certain cases of pain and discomfort in the abdomen in which laparotomy leads to a cure, and presumably the effect upon the two large serous surfaces, the peritoneum and the lining of the knee-joint, when they are exposed is similar and at present equally obscure. In the case of the abdomen such instances are most commonly seen in connexion with tuberculous peritonitis. Possibly similar cases in the knee-joint may represent very early instances of tuberculous affection of the synovial membrane. Or, for want of more definite knowledge, perhaps we may explain some of these cases of symptoms without apparent lesion but with excess of fluid in the joint, in the same way that we veil our ignorance in the matter of hydrocele and say that the proper balance between secretion and absorption is upset in the joints in question. If then we continue to use the term "internal derangement," we must realise that in so describing a case we do not infer that the lesion is necessarily one of a semilunar cartilage. Having now had the opportunity of operating upon a considerable number of such cases, it seemed to me that to put them on record with a brief statement of the actual lesion present in each case might serve a useful purpose by illustrating the various conditions that may produce similar symptoms and demonstrating the consequent difficulty of accurate diagnosis in these cases before the joint is opened. It must not therefore be assumed that I am advocating immediate and indiscriminate opening of the knee-joint in all these cases. The very opposite is, in fact, my aim, one of the main objects of this paper being to lay stress upon what I consider the proper treatment of all these cases if they are seen when the trouble has first arisen.

*Early treatment.*—Suppose a young man to have received a blow upon, or to have twisted, one of his knees. The joint became fixed for a time, very painful, and rapidly swelled. Perhaps something was felt to move or to lock in the joint. Possibly even something was felt protruding from the joint and on pushing this in the joint could be moved again. The treatment to be pursued is briefly this: splinting for a period varying from one to three weeks, followed by massage, passive movements, and properly selected exercises for the joint. The *rationale* of such treatment is that first of all rest is given so that the damage may heal, the split cartilage join, the displaced one grow firmly fixed again, the torn alar ligament mend, &c., and then the slackness of ligaments and muscles consequent upon the distension and the disuse of the joint is remedied by massage and movement. Thus the supporting structures of the joint being thoroughly restored

---

[14] It is possible that in these cases there may be (to borrow a term from ophthalmology) a slight degree of weakness, which we may call "insufficiency," of the abductors of the vocal cords.

[15] I have, however, been said to regard carpo-pedal contractions as rudimentary epileptiform convulsions. I admit that I have (Brain, vol. ix., p. 17, April, 1886) written so carelessly that it was naturally inferrible that I thought so. I there wrote "carpo-pedal contractions as well as the severer universal convulsions."

[16] I have suggested that both carpo-pedal contractions and tetany are owing to suspension of cerebral influence; in infants the Rolandic cells for the small muscles of the hand will, I submit, not be well developed, whilst those for the larger muscles moving the hand and fingers will be more developed, hence carpo-pedal contractions. In older people the cells for the small as well as the large muscles will be developed, hence tetany when the function of these cells is annulled. Moreover in infants the pyramidal tract is ill-developed.

## A Table of 59 Cases in which the Knee-joint was Opened for Symptoms of Internal Derangement.

| Case. | Sex and age. | Date. | History and symptoms. | Description of condition found at the time of operation. | Operation. | Result. |
|---|---|---|---|---|---|---|
| 1 | M., 33 years. | September, 1887. | At the Great Northern Hospital. The patient had slipped when carrying a heavy load one and a half years previously. The right knee became painful and swollen; never strong since. | The right internal semilunar cartilage freely moveable over the head of the tibia both forwards and backwards. | The cartilage was sutured to the head of the tibia. | The knee perfect two years later. |
| 2 | M., 20 years. | September, 1888. | With Dr. Wharton Hood. The patient had injured the right knee while playing football. For one year suffered recurrences of pain and swelling. A moveable body felt on the inner side of the joint. | The right internal semilunar cartilage torn away from the anterior attachment. | The semilunar cartilage was removed. No drainage. Transverse incision. | Pain from excessive synovial secretion. Five years later the knee was perfectly sound. |
| 3 | M., 21 years. | October, 1888. | With Dr. Wharton Hood. The patient had knelt on a lump of coal and twisted the left knee which became quickly swollen. After that the knee frequently gave way occasioning sickening pain. | The alar ligament torn away from its attachment to the intercondyloid notch. | The free extremity of the ligament was brought into the wound and fixed. Drainage. Internal incision. | Six months later using the knee in every way without trouble. |
| 4 | M., 30 years. | October, 1888. | At the Great Northern Hospital. For years the patient had had trouble with the left knee, thought to be due to "the small bone being out of place." A rounded body palpable on the outer side of the joint above the external tuberosity of the tibia. This sometimes disappeared. | A pendulous mass consisting of enlarged alar ligament found within the joint. | The mass of ligament was removed and the stump fixed to the lower part of the wound. External incision. | One year later had had no trouble since operation. |
| 5 | F., 26 years. | January, 1889. | At the Great Northern Hospital. Three months previously the patient had fallen from bed with the right knee under her. Sharp pain on the inner side of the knee and subsequently frequent attacks of pain on the inner side of the joint. | The internal semilunar cartilage detached and loose at the anterior extremity. | The semilunar cartilage was fixed to the head of the tibia. Drainage. Internal incision. | Eight months later perfect movement of the joint. |
| 6 | F., 31 years. | March, 1889. | At the Great Northern Hospital. One year previously the patient fell with her left knee under her; pain and swelling of the joint. The joint afterwards always ached and sometimes on rising from kneeling she felt something "jump in the joint" on the inner side. Tender spot on the inner side of the joint. | The internal semilunar cartilage very freely moveable; not detached at either end. | The cartilage was fixed to the head of the tibia. No drainage. Internal incision. | Left cured |
| 7 | M., 47 years. | March, 1889. | At the Great Northern Hospital. The patient had felt sudden pain on the outer side of the left knee when getting out of bed three months previously. The knee became fixed and painful. Similar attacks followed frequently. A small flat body palpable over the external tuberosity of the tibia. | No abnormality in the structures of the joint except some roughness of the external cartilage of the femur. | The joint was opened and explored. No drainage. External incision. | Six months later he had no further trouble. Could walk 20 miles. |
| 8 | M., 41 years. | August, 1889. | At the Great Northern Hospital. Three years previously the patient had fallen down a hole and had had great pain in the right knee. Two months before admission the pain recurred and caused him to fall. The pain and stiffness became chronic. | The internal semilunar cartilage was loose, but not detached at either end. | The cartilage was fixed to the head of the tibia. No drainage. Internal incision. | Redness round the joint. On Sept. 8th pus was let out from the lower end of the incision. Long convalescence. Discharged cured. |
| 9 | M., 22 years. | October, 1889. | At the Great Northern Hospital. The patient twisted the left knee six months before. Could often "start" a lump on the inner side of the joint. This sometimes came when walking and the knee gave way. | The left internal semilunar cartilage was torn away from the head of the tibia anteriorly. | About three-fourths of the internal semilunar cartilage were removed. Drainage. Internal incision. | Discharged "cured" in three weeks. No further history obtained. |
| 10 | M., 22 years. | February, 1890. | At the Great Northern Hospital. One and a quarter years previously the patient fell down some steps. The right knee was very swollen, and a few months later "it gave way under him and he felt a bone come out." | The internal semilunar cartilage was torn across the middle of its anterior inner part. This had left the normal semicircular groove and was lying in the antero-posterior position between the head of the tibia and the internal condyle of the femur. | The detached portion of the semilunar cartilage was removed. No drainage. Internal incision. | Discharged cured. |

The same general principle applies, I think, to all cases of insanity except total dementia and to cases of partial aphasia.

I have not forgotten that laryngeal crises occur in some tabetic patients who have no discoverable paralysis of the abductor muscles of the vocal cords (Semon); to these[14] the foregoing hypothesis does not, it may well be said, apply. But there may in them be the "irritative" state of the sensory, medulla, elements suggested. And once more I urge, having regard to the effects of experimental stimulation of the superior laryngeal nerve, that the nisus of the Respiratory centre when it is stimulated from the "irritative" sensory elements representing the laryngeal mucous membrane, is for expiration, for narrowing of the glottis. I suggest that in the cases where the abductor muscles are not discoverably paralysed the "irritative state" of the medulla sensory elements representing part of the mucous membrane of the larynx is very great.

I will now mention some things which I think ought to be considered when we witness a laryngeal crisis of a tabetic. The limbs are, it is said, convulsed in some severe attacks. But perhaps in some of these attacks there occur only writhings of the limbs as an indirect consequence of arrest of respiration; these writhings, being movements proper, ought not to be confounded with convulsion proper, as I believe is done in accounts of some slight cerebral paroxysms commonly called epileptic. If the limbs were the subject of such an intense discharge as produces convulsion there could not be movements even so little elaborate as those of writhing: there would be tonic or clonic spasm of them and not movements properly so-called. In any case of fits, epileptic or of any other sort, we ought to note the condition of the chest and *whether or not the fit begins thoracically*—begins by fixation of the chest walls or by mere cessation of respiration—with subsequent involvement of the limbs.

I here state the hypothesis regarding patients rendered hemiplegic in infancy by a *cerebral* lesion and who later in life become subject to fits, that in some of the cases the fits are *not cerebral* but bulbar (lowest level fits). Certainly very careful attention should be given to the paroxysms in this clinical group of "epilepsies" to determine whether the *onset* is thoracic, more generally by convulsion of the bilaterally acting muscles (trunk) or by convulsion of the limbs. (So, too, for observations of fits in cases of general paralysis.)

I think it possible—this is merely a speculative inference from reports of friends of patients—that there may occur in some stage of a laryngeal crisis terminal tonic spasms like those of tetany. Such terminal tonic spasms are certainly, in no kind of malady, parts of convulsion proper.[15] We should note whether or not the patient perspires very much during the crisis (supervenosity would account for sweating) If he be deeply asphyxiated, we should note whether his knee-jerks are present or absent (no doubt, however, in nearly every case they will be absent at all times, as part of the tabetic symptomatology). Is there passage of urine or fæces in or just after severe seizures? The passage of fæces might be a result of great venosity and thus not a part of the fit proper, or at least a very indirect result of the nervous discharges in the fit.

In some cases of whooping-cough there occur convulsions which are, I suppose, caused by highly supervenous blood (consequent on severe cough-paroxysms) over-stimulating the respiratory centre. Whether, when in these cases there is considerable supervenosity but no convulsion, there are ever carpo-pedal contractions, I do not know. I believe that these persisting terminal tonic spasms are owing, indirectly, to suspension of the influence of certain cells of the Rolandic cortex, and that when they occur in rickety children in association with, in the intervals of, attacks of laryngismus stridulus, and in some other cases, the cerebral influence is suspended owing to supervenosity annulling the function of small cells of the hand area of the Rolandic cortex. The spasm itself is owing *directly* to permitted over-action of cells of anterior horns for the hands and, as I think, also by non-antagonised cerebellar influence upon those horns, cerebral influence on them being suspended.[16] The *attacks* of laryngismus stridulus in rickety infants are, I have tried to show (*Brain*, April, 1886), lowest level fits caused by very great stimulation of the Respiratory centre by supervenous blood.

# SOME REMARKS UPON "INTERNAL DERANGEMENT" OF THE KNEE-JOINT:

BASED UPON 59 CASES IN WHICH OPERATION WAS PERFORMED.

BY HERBERT W. ALLINGHAM, F.R.C.S. ENG.,
SURGEON-IN-ORDINARY TO H.R.H. THE PRINCE OF WALES; SURGEON TO THE HOUSEHOLD OF HIS MAJESTY THE KING; ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL.

"INTERNAL derangement of the knee-joint" is a term that was used originally to describe cases having a well-defined series of symptoms, in which the lesion was held to be always damage or displacement of one of the semilunar cartilages. Since the publication of my book on this subject in 1889 I have met with a variety of cases in point which it may now be of use to put forward. We know now that the trouble within the joint is by no means always of the nature mentioned above.

*Variety of lesion.*—The fact is that a considerable variety of lesions in the knee-joint may all cause the symptoms common to cases known as examples of internal derangement. Moreover, some cases present these symptoms and improve after the joint is opened, although no lesion at all is discerned. This seems just analogous to what happens in certain cases of pain and discomfort in the abdomen in which laparotomy leads to a cure, and presumably the effect upon the two large serous surfaces, the peritoneum and the lining of the knee-joint, when they are exposed is similar and at present equally obscure. In the case of the abdomen such instances are most commonly seen in connexion with tuberculous peritonitis. Possibly similar cases in the knee-joint may represent very early instances of tuberculous affection of the synovial membrane. Or, for want of more definite knowledge, perhaps we may explain some of these cases of symptoms without apparent lesion but with excess of fluid in the joint, in the same way that we veil our ignorance in the matter of hydrocele and say that the proper balance between secretion and absorption is upset in the joints in question. If then we continue to use the term "internal derangement," we must realise that in so describing a case we do not infer that the lesion is necessarily one of a semilunar cartilage. Having now had the opportunity of operating upon a considerable number of such cases, it seemed to me that to put them on record with a brief statement of the actual lesion present in each case might serve a useful purpose by illustrating the various conditions that may produce similar symptoms and demonstrating the consequent difficulty of accurate diagnosis in these cases before the joint is opened It must not therefore be assumed that I am advocating immediate and indiscriminate opening of the knee-joint in all these cases. The very opposite is, in fact, my aim, one of the main objects of this paper being to lay stress upon what I consider the proper treatment of all these cases if they are seen when the trouble has first arisen.

*Early treatment* —Suppose a young man to have received a blow upon, or to have twisted, one of his knees. The joint became fixed for a time, very painful, and rapidly swelled. Perhaps something was felt to move or to lock in the joint. Possibly even something was felt protruding from the joint and on pushing this in the joint could be moved again. The treatment to be pursued is briefly this: splinting for a period varying from one to three weeks, followed by massage, passive movements, and properly selected exercises for the joint. The *rationale* of such treatment is that first of all rest is given so that the damage may heal, the split cartilage join, the displaced one grow firmly fixed again, the torn alar ligament mend, &c, and then the slackness of ligaments and muscles consequent upon the distension and the disuse of the joint is remedied by massage and movement. Thus the supporting structures of the joint being thoroughly restored

---

[14] It is possible that in these cases there may be (to borrow a term from ophthalmology) a slight degree of weakness, which we may call "insufficiency," of the abductors of the vocal cords.

[15] I have, however, been said to regard carpo-pedal contractions as rudimentary epileptiform convulsions. I admit that I have (Brain, vol. ix., p. 17, April, 1886) written so carelessly that it was naturally inferrible that I thought so I there wrote "carpo-pedal contractions as well as the severer universal convulsions."

[16] I have suggested that both carpo-pedal contractions and tetany are owing to suspension of cerebral influence; in infants the Rolandic cells for the small muscles of the hand will, I submit, not be well developed, whilst those for the larger muscles moving the hand and fingers will be more developed, hence carpo-pedal contractions. In older people the cells for the small as well as the large muscles will be developed, hence tetany when the function of these cells is annulled. Moreover in infants the pyramidal tract is ill-developed.

A TABLE OF 59 CASES IN WHICH THE KNEE-JOINT WAS OPENED FOR SYMPTOMS OF INTERNAL DERANGEMENT—*(Continued)*.

| Case. | Sex and age. | Date. | History and symptoms. | Description of condition found at the time of operation. | Operation. | Result. |
|---|---|---|---|---|---|---|
| 23 | M., 17 years. | November, 1891. | With Dr. M. Prickett. Two years previously the patient injured his left knee at football. Entrance to army was now refused on account of the condition of this joint. | The internal semilunar cartilage was so loose that it could be folded back into the joint; it was not detached from either extremity. | As much as possible of the internal semilunar cartilage was cut away and removed. | After three weeks an anæsthetic and massage were required for stiffness. A perfect result. The patient was accepted into the army and seven years later he had experienced no trouble. |
| 24 | M., 46 years. | December, 1891. | At the Great Northern Hospital. There had been pain and effusion into the left knee-joint at times for years. | There was much thickening of the synovial membrane. An osteophytic deposit in the joint was felt directly the finger was inserted into the inner side of the joint. | The osteophytic growth was removed. Drainage for 10 days. Internal incision. | Two years later movement of the joint was free in every direction. No attacks of pain or swelling. |
| 25 | M., 26 years. | December, 1891. | At the Great Northern Hospital. The right knee was swollen and painful off and on for 10 years. It was always weak. There was a small lump on the inner side of the knee. | There was an excess of fluid. The synovial capsule was thickened. There was no loose body. The inner condyle of the femur was rough and was studded with irregular outgrowths. An osteophyte of the size of a large pea was found on the inner side of the tibial head. | The osteophyte was removed. Drainage. Internal incision. | One year later the joint was quite well and was freely moveable. |
| 26 | M., 24 years. | May, 1892. | Injured right knee while hunting two years previously. | The internal semilunar cartilage was torn from the coronary attachment; it was not separated at the anterior or posterior extremity. | The cartilage was stitched to the head of the tibia. Drainage. | Rapid recovery. |
| 27 | M., 24 years. | May, 1892. | At the Great Northern Hospital. Five years previously the patient had injured the left knee by jumping from a train. There had been constant pain since. | The anterior part of the internal semilunar cartilage was curled on itself and was torn away from the attachment to the internal tuberosity. | The condition of the cartilage was only fully seen on extreme flexion of the joint after opening. Most of the internal semilunar cartilage was removed. Drainage. | There was considerable oozing of synovia for three weeks. Two months later there was some stiffness of the joint. |
| 28 | M., 22 years. | October, 1892. | In private practice. Two years previously the patient had injured his left knee at football and there had been repeated attacks of pain since. | The internal semilunar cartilage was freely moveable though not torn away from its attachments. It could be slipped in and out of the joint. | The cartilage sutured to the head of the tibia. Internal incision. | Three years later the joint was perfect. |
| 29 | F., 27 years. | October, 1892. | At the Great Northern Hospital. The patient had hurt her right knee at the age of five years. Stiffness of the joint with frequent attacks of pain, swelling, and sometimes locking had been experienced since. | The synovial membrane was thickened and nodular. | The joint was washed out and drained. | The patient left the hospital in 14 days with the wound healed. No further history was obtained. |
| 30 | F., 26 years. | February, 1893. | At the Great Northern Hospital. For some years the patient had felt something slipping in the left knee. She was liable to fall. | The internal semilunar cartilage was freely moveable but not unattached. | The cartilage was sutured to the head of the tibia. Internal incision. | The patient left the hospital well after five weeks and has not been heard of since. |
| 31 | M., 30 years. | February, 1893. | With Dr. Wharton Hood. For years the patient had been subject to "slipping" and to pain in the left knee. | The internal semilunar cartilage was very moveable, was torn away from the anterior attachment, and was curled up. | The cartilage was removed. Drainage. Internal incision. | Rapid recovery. Three years later the patient was playing tennis with perfect comfort. |
| 32 | M., 32 years. | April, 1893. | In private practice. The patient suffered from pain and occasional locking of the right knee for two years. | A small portion of internal semilunar cartilage was torn away from its anterior attachment. | The loose cartilage was removed. No drainage. | lower<br>cision.<br>cence.<br>Rapid recovery. stitches were re on the fi patie th |
| 33 | M., 32 years. | July, 1893. | At the Great Northern Hospital. Ten years previously the patient had damaged the right knee at football, and there had been pain frequently since. | The internal semilunar cartilage was torn away from its anterior attachment. | The internal semilunar cartilage was removed. | Discharged "cured" in three weeks. No further history obtained. |
| 34 | M., 21 years. | November, 1893. | At the Great Northern Hospital. Four years previously the patient had felt a lump at the back of the inner side of the joint. It could be pushed away. There had been severe attacks of pain and swelling. | A free cartilaginous lump slipped out when the joint was opened. | Incision over th ing at the inner the knee. ortion of cartilage ed. No ternal in- | Discharged cured. |
|  |  | November, 1893. | With Dr. A. W. K. Picard. One and a half years previously the patient had received a blow on the left knee at cricket. A year later he felt something moving in the joint. | There was a free piece of cartilage. | On opening the the inner si finger could loose body. Th was freely was and a piece of came away |  |

A TABLE OF 59 CASES IN WHICH THE KNEE JOINT WAS OPENED FOR SYMPTOMS OF INTERNAL DERANGEMENT—*(Continued)*

| Case | Sex and age | Date | History and symptoms | Description of condition found at the time of operation | Operation | Result |
|---|---|---|---|---|---|---|
| 11 | M, 20 years | February, 1890 | At the Great Northern Hospital Four years previously the patient had slipped and had hurt the left knee There was pain which was relieved by something going back when he tried to walk There were frequent recurrences | The coronary ligament of internal semilunar cartilage was very relaxed allowing free movement | The cartilage was sutured in the head of the tibia | For several days the dressings were stained with synovial fluid One month later the stiffness of the joint was broken down under gas Discharged cured after two months |
| 12 | F, 33 years | April, 1890 | At the Great Northern Hospital Two years previously the patient had fallen and had bruised the left knee There was a gnawing pain in the knee frequently The movements of the joint were natural but a body was thought to be felt in joint above the patella on flexion | No abnormality was found in the joint except some excess of synovial fluid | The joint was opened and explored | Rapid convalescence No further trouble in the knee |
| 13 | M, 39 years | May, 1890 | At the Great Northern Hospital Five years previously the patient had ricked his right knee which had to be pulled in | The internal semilunar cartilage was very loose and a cystic excrescence was attached to its outer side | The internal semilunar cartilage was removed | Discharged cured after six weeks |
| 14 | M, 23 years | June 1890 | With Dr Wharton Hood Frequent trouble with the right knee since encountering an accident while at football | A piece of loose cartilage of the size of a bean was found on the external side of joint | The loose piece of cartilage was removed No drainage External incision | Much effusion requiring early removal of the stitches The knee gave no further trouble for 10 years |
| 15 | M, 33 years | January, 1891 | At the Great Northern Hospital In 1888 'something snapped in the right knee' and the patient had had trouble ever since | The anterior part of the internal semilunar cartilage was detached and apparently divided into two The larger portion was lying between the condyles of the femur the other lying free on the tibia | Portions of cartilage were removed Drainage Internal incision | Pain for some days after operation When seen six months later the patient was quite well |
| 16 | M 21 years | February, 1891 | With Dr Wharton Hood The left knee had been twisted at football There had been constant trouble with occasional fixation of the joint since | The internal semilunar cartilage was detached from its base centrally but was fixed at each end | The internal semilunar cartilage was removed The joint was washed out Drainage Internal incision | Oozing of synovia for several weeks Adhesions broken down after six weeks Perfect condition of the joint giving no trouble at the end of six months |
| 17 | M, 24 years | July, 1891 | At the Great Northern Hospital Three years previously the patient had slipped while he was unloading a barrow There had been frequent attacks of pain in the right knee ever since | The internal semilunar cartilage was loose and displaced anteriorly | The semilunar cartilage was removed Drainage Internal incision | Rapid convalescence No return of symptoms six months later |
| 18 | M, 24 years | August 1891 | At the Great Northern Hospital Two and a quarter years previously the patient had hurt the right knee at football Soon afterwards the knee suddenly gave way under him and there had been several recurrences later | The anterior portion of the internal semilunar cartilage was detached and was lying loose | The anterior two-thirds of the cartilage were removed Drainage Internal incision | After one month the knee was slightly stiff Six months later this had gone and the knee was perfect |
| 19 | M, 40 years | September 1891 | With Dr Wharton Hood For 10 years there had been symptoms of a loose cartilage in the right knee | Loose cartilage was found in the synovial pouch to the outer side of the patella | Removal of the loose piece of cartilage No drainage External incision | Rapid convalescence The patient went home in a week No further trouble two years later |
| 20 | M 36 years | September 1891 | With Dr Wharton Wood Injured the knee joint when rowing 10 years previously For the last four years there were frequent attacks of pain and swelling | A small extra piece of cartilage found attached to inner side of the joint just above the internal semilunar cartilage | A piece of cartilage was removed from the inner side of the joint Internal incision | Rapid convalescence The knee perfectly well five years later |
| 21 | M, 38 years | October 1891 | With Mr B Carter Two years previously the patient injured the left knee while hunting There had been stiffness pain and effusion frequently since Riding and all active exercise were prevented | The internal semilunar cartilage was very loose but not separated from its attachments | The cartilage was sutured to the head of the tibia Drainage | A few adhesions at the end of a fortnight Massage and movement for two weeks When seen three years later the patient had been perfectly well ever since |
| 22 | M, 37 years | October 1891 | With Dr Wharton Hood For years the patient had suffered from pain in the left knee-joint the original injury having been received while bowling at cricket | The internal semilunar cartilage was freely moveable being torn away from the base but not separated from either extremity | The cartilage was fixed to the head of the tibia. Drainage | Excessive secretion of synovia continued for one month Stiffness of the joint was broken down under an anaesthetic but it returned in spite of massage and movements The knee remained stiff |

A TABLE OF 59 CASES IN WHICH THE KNEE-JOINT WAS OPENED FOR SYMPTOMS OF INTERNAL DERANGEMENT—(*Continued*).

| Case. | Sex and age. | Date. | History and symptoms. | Description of condition found at the time of operation. | Operation. | Result. |
|---|---|---|---|---|---|---|
| 48 | M., 21 years. | April, 1899. | At the Great Northern Hospital. There had been symptoms of a loose body in the right knee for one year. | The internal semilunar cartilage was loose, but not torn away from its attachment. The alar ligament was torn away on the inner side. | The loose alar ligament was removed and the semilunar cartilage was stitched to the head of the tibia. | The patient went out cured in three weeks and was well a year later. |
| 49 | M., 24 years. | May, 1897. | With Dr. Wharton Hood. There had been symptoms of loose cartilage in the right knee. | The internal semilunar cartilage was split. | The smaller piece of the split semilunar cartilage was removed. No drainage. Internal incision. | Perfect progress was made, and the patient remained free from symptoms two years later. |
| 50 | M., 28 years. | July, 1897. | In private practice. The right knee had been constantly giving pain while riding. Sometimes it swelled up. | The internal semilunar cartilage was found to be loosed from the coronary ligaments, but was attached at each extremity. | The internal semilunar cartilage was removed. Internal incision. | Rapid recovery. No trouble since. The patient was seen in January, 1902. |
| 51 | M., 37 years. | July, 1897. | In private practice. There had been pain and weakness in the left knee, which had interfered with military duties. | The internal semilunar cartilage was loose, but was not detached at either end. | The cartilage was sutured to the head of the tibia. | See note at end of table. |
| 52 | M., 32 years. | January, 1898. | With Dr. Wharton Hood. There had been symptoms of loose cartilage in the left knee. | There was no looseness of either cartilage, but a roughened condition of the cartilage of internal condyle of femur was present. | The joint was opened and explored. No drainage. | Rapid recovery. No further symptoms. |
| 53 | M., 25 years. | March, 1898. | With Dr. Robinson. The condition of the patient's right knee had interfered with his entrance to the army. | The right internal semilunar cartilage was torn from the coronary ligament, but was attached at the extremities. | The loose internal semilunar cartilage was removed. Internal incision. | Rapid recovery. The patient entered the army, and up to December, 1901, had not been troubled with the knee. |
| 54 | M., 27 years. | May, 1899. | In private practice. There had been symptoms of internal derangement for six months. | The internal semilunar cartilage of the right knee was split and was very moveable. | Cartilage removed. Internal incision. | Rapid recovery. Cure. The patient was seen two years later. |
| 55 | M., 35 years. | May, 1899. | At St. George's Hospital. Symptoms of internal derangement had been manifest. | The interior of the joint and ligaments was normal. | The joint was opened and explored. The cartilage was not removed. | Discharged cured. |
| 56 | M., 28 years. | June, 1900. | In private practice. There had been pain and frequent attacks of swelling in the right knee. | The internal semilunar cartilage was torn away from the posterior attachment. | The cartilage was removed. No drainage. Internal incision. | Rapid recovery. The patient has been well since. He was seen in December, 1901. |
| 57 | M., 33 years. | August, 1900. | At St. George's Hospital. Attacks of pain and stiffness in the right knee on the outer side had interfered with work. | The cartilages were normal. There was an excessive fringe of synovial membrane. | The excessive synovial fringe was removed. No drainage. External incision. | Rapid recovery. T patient has not be heard of since. |
|  | M., 33 years. | February, 1901. | In private practice. Symptoms of internal derangement had prevailed for three months in the right knee. | The internal semilunar cartilage was very moveable but was not torn away from its extreme attachment. | The cartilage was removed. No drainage. Internal incision. | Rapid recovery. Cure. |
| 59 | M., 26 years. | November, 1901. | In private practice. The right knee had been first damaged at football three years previously. Since then it had been constantly giving way on severe exercise. | Directly the joint was opened the loose body jumped into the wound. No other abnormality was found. | The loose body was removed. No drainage. Internal incision. | Rapid recovery. There has been no return of the symptoms up to the present date though a hard day's shooting has been indulged in. |

CASE 51.—There was pain in the joint from the day after the operation. The temperature was never above 100° F., but the condition of the joint was unsatisfactory. There were a pulpy condition of the synovial membrane and cellulitis superficially. The stitches were removed and the joint was washed out. There were always pain and discharge of synovial fluid. The knee remained swollen and painful and was opened to let out the discharge on two occasions. There was not much discharge of synovia, but there was constant pain. Finally the joint quieted down but it remained absolutely ankylosed.

A TABLE OF 59 CASES IN WHICH THE KNEE-JOINT WAS OPENED FOR SYMPTOMS OF INTERNAL DERANGEMENT—*(Continued).*

| Case. | Sex and age. | Date. | History and symptoms. | Description of condition found at the time of operation | Operation. | Result. |
|---|---|---|---|---|---|---|
| 36 | M., 22 years. | January, 1894. | At the Great Northern Hospital. The patient dislocated the left knee at football one and a quarter years before There had been frequent pain. A lump was observed on the inner side of the knee-cap. | The internal semilunar cartilage was quite loose, was torn away from the posterior attachment, and was curled up. | The internal semilunar cartilage was removed. | One year later the knee was perfect in all respects. |
| 37 | M., 30 years. | January, 1894. | With Dr. Wharton Hood. The patient injured the left knee when rowing six years previously. All the symptoms of loose external cartilage were present. | The external semilunar cartilage was natural. There was a small pedunculated piece of cartilage under the patella on the outer side of the joint. | A loose piece of cartilage was removed. | The stitches were removed on the sixth day when a good deal of synovia escaped. Massage was required to overcome the stiffness. The patient was eventually quite cured. |
| 38 | M., 29 years. | March, 1894. | At the Great Northern Hospital. The patient had injured the left knee while skating some years before, and there had been trouble since on the inner side. | The internal semilunar cartilage was split. There was a tongue like process projecting into the joint. | The internal semilunar cartilage was removed. Drainage for one week. | Rapid recovery. Cure. |
| 39 | F., 33 years. | April, 1894 | At the Great Northern Hospital. There was frequent pain in the right knee for years which was worse on the outer side of the joint. | The external semilunar cartilage was found to be chipped. | The protruding portion of cartilage was cut away. No drainage. External incision. | Rapid recovery. Cure. |
| 40 | M., 40 years. | June, 1894. | With Dr. Wharton Hood. The patient had fallen while hunting and had struck the right knee seven years previously. There were symptoms of loose cartilage which prevented extension of the leg. | A free loose cartilage was found in the synovial pouch about the patella There was much nodular outgrowth from the synovial membrane. | The loose cartilage and the synovial thickenings were removed. | Rapid recovery. Much improvement in the range of the joint movement. |
| 41 | M., 50 years. | June, 1894. | At the Great Northern Hospital Three months previously, while removing his stocking, the patient had noticed a small lump come up in front of the right knee. He could not straighten the knee for two days when he forced the lump to the inner side of the knee cap It afterwards passed to the outer side, where it stayed. | There was a cartilaginous lump in the synovial pouch to the outer side of the patella. | The cartilaginous lump was removed. | Rapid recovery. |
| 42 | M., 37 years. | October, 1894. | With Dr. Wharton Hood. There had been pain and discomfort in the right knee for some years A loose body was felt wandering about the joint. | A small piece of free loose cartilage was found towards the back of the joint. | The loose body was removed. No drainage. Internal incision. | Rapid recovery. Cure. The patient was well four years later. |
| 43 | M., 30 years. | April, 1895. | With Dr. M. Prickett. There had been symptoms of loose cartilage for two years. | The right internal semilunar cartilage was very moveable but was not torn from its attachments. | The cartilage was sutured to the head of the tibia. No drainage. | Rapid recovery. Cure. The patient was well three years later. |
| 44 | M., 57 years. | June, 1895. | At the Great Northern Hospital. The patient had knocked the left foot against a stone and had twisted the knee a year previously. He had since felt clicking in the joint. | The cartilaginous surface of the inner condyle of the femur was hypertrophied. The capsule of the joint was very thick where it was opened. | Joint examined. No drainage. Internal *incision.* | Rapid recovery, with movement of the joint *and freedom from* the clicking sensation. |
| 20 | M., years. | January, 1896. | With Dr. Wharton Hood. There had been symptoms of a loose body in the right knee-joint for some months. Just before the operation the loose body was demonstrated by the patient and was felt by Dr. Wharton Hood and myself. | The condition of the joint structures was normal. The loose body was not discoverable; complete flushing of joint with water failed to wash out the body, which went into the back of the joint. | Free exploration and washing of joint. Internal incision. | Rapid recovery. No further symptoms when the patient was seen three years later. |
| 21 | M., 38 years. | Octobe 1891.<br>h, | With Mr. L. Jones of Manchester. There had been symptoms of a loose body in the right knee for one year.<br>all<br>ve. | The right internal semilunar cartilage was torn away from its posterior attachment. It was freely moveable in the joint. | The cartilage was cut away from the interior attachment and was removed The ligamentous joint structures were very loose. | Rapid recovery. The patient who was seen in 1901 had been well ever since. |
| 22 | M., 37 years. | October, 1891. | Wit For St. George's Hospital. Five suf onths previously the patient kn el fallen and had twisted the ha ft knee, which became fixed bc r some hours. A small body hich was moveable up and own was palpable over the uter edge of the outer condyle f the femur. | The synovial membrane was thick in position of the body felt before operation. No loose body. | The small fold of thickened membrane was removed. No drainage. | Rapid recovery. Symptoms relieved. |

time. As he did not improve, for the sake of a holiday, he paid a visit to his daughter in Essex. Shortly after his arrival he developed difficulty in swallowing and soon had to limit his food to semi-solids and finally liquids. The latter, however, frequently regurgitated through the nose.

After he had been in Essex about three days he was seen by one of us and again carefully examined. He was then well nourished and when sitting down looked in good health except for his ptosis. He complained of weakness; but on examination it was found that he could fairly well perform any movement of the limbs or trunk. Any such movement, however, was almost immediately exhausted; for instance, he could rise from his chair fairly briskly for a man of his age; a second attempt to do this involved great effort and a third attempt was quite unsuccessful. There was no muscular wasting and the electrical irritability of the muscles was not examined. There was no loss of sensation in any part of the body, nor was there any incoördination, tremor, or involuntary movement of any kind. The abdominal and plantar reflexes were normal. The knee-jerk was at first somewhat exaggerated but became partially exhausted on repeated stimulation. As far as could be determined, however, the knee jerk could not be absolutely abolished. There was no clonus. There was no ocular palsy, but some nystagmoid jerking occurred on lateral deviation of the eyes, which jerking increased if the lateral deviation was prolonged. There was no history of diplopia. Bilateral ptosis was present to a degree sufficient about half to cover the pupils, but the ptosis increased if the patient attempted to read. The pupils were equal and the pupillary and conjunctival reflexes were normal. There appeared to be no weakness of the muscles of mastication or of the muscles of the face. The patient's voice was fairly strong after a rest of half an hour or so, but aphonia developed after a few minutes' conversation. He was unable to swallow solid food. The pharyngeal reflex could not be obtained. Liquids regurgitated through the nose towards the end of a meal. The heart and lungs were normal except that the aortic second sound was louder than natural. His arteries were normal for his age. The patient had full control of his rectum and bladder. At this time the urine contained both sugar and albumin in moderate amounts. The patient rapidly grew worse and returned to Plymouth on June 27th. On the 29th difficulty of swallowing became more pronounced and it increased daily until his death on July 13th.

No necropsy was obtained in this case, but there appears to be little doubt that our patient suffered from myasthenia gravis or asthenic bulbar paralysis. The unusual features to which we would draw attention are the patient's age, the exceptionally acute course of the disease, and the association with diabetes. From previously reported cases (about 70 in number) it would appear that the disease belongs to the third decade of life, and so far as we have seen in the literature no case is on record of such a patient who has reached the seventh decade. Erb's first case—the oldest at present on record—was 55 years of age.

The present case ran an exceptionally acute course. The only undoubted case that has run a more acute course is that recorded by Widal and Marinesco; their patient lived only 14 days after the onset. The association with diabetes in our case appears to have been somewhat intimate since the myasthenia set in almost as soon as the patient relaxed his diabetic diet. So far as this observation goes it is in favour of the prevalent view that myasthenia gravis is due to the effect of some toxic agent upon the peripheral neurons.

# MILK OR WHEY IN ENTERIC FEVER?

BY ARTHUR TREGELLES PRIDHAM, M.B. LOND.,
HOUSE PHYSICIAN AT ST. BARTHOLOMEW'S HOSPITAL.

IN THE LANCET of Nov. 2nd, 1901, p. 1182, Mr. Prideaux G. Selby of Teynham, Kent, published a paper concerning the treatment of enteric fever by whey instead of milk as a taple food, his death-rate for 73 cases being 2 7 per cent Since that time Dr. S. J. Gee of St. Bartholomew's Hospital has treated four cases entirely, and one case partially, by this method. All did well, but one case perhaps deserves notice on account of its severity and the favourable issue under what is more or less a new departure in treatment, ich I believe that Dr. Norman Moore has for some time past treated his cases of enteric fever chiefly on whey. The patient in question was a man, aged 23 years, a fish-porter, and previously to this illness he had been in good health. On Nov. 3rd, 1901, he caught cold and suffered from headache, and on the 10th he took to his bed. On the 16th he was admitted into St. Bartholomew's Hospital, with the history that for the previous week he had been feverish and his bowels constipated. On admission his temperature was 100·5° F.; his pulse was 84 per minute, soft and regular; his radial artery was thickened; his urine was of specific gravity 1025, had an acid reaction, and presented no abnormality; and his tongue was dry and brown. Examination of his heart and lungs showed nothing abnormal. His abdomen was not distended or tender; his spleen could just be felt. On the 17th his blood gave a well-marked Widal's reaction. On Dec. 2nd there were many typical enteric fever spots on his abdomen and chest. His evening temperature was usually from 103° to 104°, and his pulse was from 110 to 120 per minute and very soft; he was sponged night and morning. He was taking four ounces of brandy and a small quantity (about half a pint) of beef essence; otherwise he had nothing but whey, of which he consumed from three to four pints in the 24 hours On Dec. 4th there were some indications of heart failure and the first sound became faint. The patient therefore began to take four-minim doses of liquor strychniæ, given at first three times a day and afterwards every six hours. On the 6th his pulse was very soft and dicrotic and he had occasional shivering fits. His bowels were open about three times daily; on the 6th the motions were stained with blood, and he passed one very large black slough measuring one inch by half an inch, together with several small sloughs; they were of considerable thickness, showing the ulceration to be very deep. His abdomen presented no distension and was natural in appearance. On the 9th several large blood-stained sloughs were passed. On the 10th the man was very ill and the brandy was gradually increased till he now took eight ounces. About 3 A.M. on the 12th, which was approximately the fortieth day of the disease, there was copious hæmorrhage from the bowel amounting to at least one and a half pints; the man was very ill, but he quieted down with morphia given hypodermically. On the 13th the patient was so collapsed and blanched that Dr. Gee gave an unfavourable prognosis. There was, however, no delirium or distension of the abdomen. On the 16th the patient was very restless, he passed urine frequently, and was with great difficulty made to sleep by hypodermic injections of morphia, hot sponging, and paraldehyde On the 17th his urine was alkaline and contained much pus and the bacillus typhosus; he was given seven grains of urotropine three times a day. On the 18th he was better and the urine was clearing. On the 19th there was an obvious improvement. His bowels were opened twice, the motions containing no blood or sloughs. His tongue was cleaner and for the first time since the hæmorrhage he had strength to put it out when asked to do so. On the 20th the man was better. His temperature was intermitting well and his urine contained no pus. On the 21st (the forty-ninth day of the disease) his temperature was normal, his subsequent convalescence was uninterrupted, and the brandy was gradually reduced. He continued to take nothing but whey until the 31st, when he began to take milk. He was very emaciated, but not more so than might have been expected from the severity of the disease.

The most noticeable points in the case were the following. 1. Distension of the abdomen was entirely absent. Another patient with enteric fever who was taking half a pint of milk with his whey showed more distension on the third day after admission than this patient did at any time throughout his illness. From the size and thickness of the sloughs I am convinced that had the patient's intestines been distended with gas when he passed these sloughs perforation must have followed. 2. There was an absence of delirium almost throughout the illness, except for a short time on one or two occasions. 3 There was an absence of serious diarrhœa in spite of the severe ulceration; the bowels were loose but never became troublesome. It is probable, as suggested by Mr. Selby, that these three symptoms are often much aggravated by, or due to, toxins formed by decomposing milk curd. 4 With regard to the state of the mouth and tongue it did not correspond to Mr. Selby's experience and differed little from than of an enteric fever patient treated with milk, being dry and cracked and difficult to keep clean.

St. Bartholomew's Hospital, E.C.

to their natural strength, when the joint is again fully used in the ordinary way there will be no tendency to a recurrence of the accident. Such a line of treatment is that which has been followed for years with the greatest success by Dr. Wharton P. Hood. In a certain percentage of cases it will fail and the trouble will recur. These must be operated upon Similarly chronic cases that have already had numerous attacks when first seen require operation. Those cases, also, in which a quite loose body can be felt to move to widely different positions in the joint and those in which a loosened cartilage protrudes from the joint will not improve without operation. In all other cases such a course of treatment as has been sketched should be thoroughly tried before the question of operation is considered.

*The operation.*—A few particulars concerning the operation itself may be mentioned. A vertical incision of about three inches, one inch to the inner side of the patella and going down to an inch below the head of the tibia is the incision which I choose for opening the joint, unless, of course, there is special indication, as the presence of a foreign body, for incising at some other situation. An advantage over the transverse incision is that by the vertical cut, the extension of the vasti on to the tibia, an important supporting structure *is not divided; moreover, the vertical incision is easily* prolonged upwards when this is necessary for examination of the large synovial pouch about the patella. Care must be taken to clip and to tie every bleeding point, and the joint is to be literally squeezed dry before it is closed. The joint should not be washed out with antiseptics and no drainage should be employed. One exception to the rule of not washing out is presented by such cases as Case 35 Here a loose body, the presence of which had been determined with certainty before the joint was opened, could not afterwards be found in spite of the freest digital searching. On flushing the joint with boiled water the body literally floated out. Such a manœuvre may occasionally be necessary and has led to no harm. In another case (Case 45) even this proceeding failed to discover a loose body about the presence of which there was absolutely no doubt. It became fixed presumably in the posterior part of the joint behind the crucial ligaments and gave no further trouble. The course of this case to a perfect cure seems to prove conclusively that rest, exercise, and massage may lead to the remedying of a condition within the knee-joint which might well have seemed incurable except by operation. It is, however, possible that the body became fixed owing to influences which would not have come into play had the joint not been opened.

It is hardly necessary to insist upon the strictest asepsis, which must, of course, be observed, but I cannot agree with Mr A. E. Barker that the finger should not be used within the joint. Without such use I cannot believe it possible in some cases properly to estimate or to remedy the fault that may be present. It is necessary in some cases to examine with the finger every part of the joint that can be reached. Even then a small loose body may escape detection as in Case 45

My experience favours removing loose semilunar cartilages rather than fixing them, and the *same* applies to torn or hypertrophied alar ligaments or local hypertrophy of synovial membrane.

In closing the wound the sutures are to be passed so as to include the cut synovial membrane.

*After-treatment.*—The splints are to be taken off within a week. Passive movements are begun as soon as the skin wound is healed, and these are combined with massage If in spite of exercises and massage there appears some stiffness of the joint *it must be freely moved under an anæsthetic* and then daily massaged and freely moved to prevent stiffness from reappearing

*Points concerning diagnosis.*—The 59 cases here tabulated, all of which presented either the characteristic symptoms with locking of the joint, or else weakness with recurrence of pain and swelling, which is often the only evidence of damaged semilunars, illustrate the following conditions: (1) semilunar cartilage, internal or external, split, loosened or displaced, torn *from either or both extremities or from* coronary ligaments; (2) loose bodies—the body may be quite free or may be attached by a pedicle; (3) a torn or hypertrophied alar ligament or hypertrophied fringe of synovial membrane; (4) rheumatoid arthritis—roughened cartilage, thickened synovial membrane, and osteophytic outgrowth; and (5) no obvious derangement. There are some points which help us in differentiating between these conditions, although it will happen not seldom that symptoms most strongly suggestive of one lesion will prove to be due to another. Thus Case 59 was apparently a typical example of semilunar damage, yet the lesion proved to be a perfectly loose body and the semilunars were natural.

In the cases of damage to a semilunar cartilage there are generally these features: (1) distinct history of injury originating the trouble; (2) a well-defined site of pain on the inner or outer side of the knee according to the cartilage damaged; (3) no foreign body palpable; and (4) no creaking in the joint. These same features also characterise generally cases in which the lesion affects an alar ligament or consists in localised hypertrophy of synovial membrane.

In the cases where a loose body is present the symptoms, again, may be exactly similar to those caused by semilunar damage (Case 59). Sometimes, however, the body will be able to be moved into widely separated portions of the joint (Case 45) and felt in its different situations. Similarly a very loose semilunar cartilage may sometimes be diagnosed with certainty through its being protruded at the side of the joint. Such a cartilage, however, may be most confusingly imitated by an excrescence due to rheumatoid arthritis.

*Results.*—Viewed generally these cases show that operation *for internal derangement of the knee-joint is in most cases* highly satisfactory. There are generally quick recovery and no recurrence of the trouble. In one case after several years of freedom another operation was required and a large number of loose bodies were removed from the joint. I am, however, very anxious not to minimise the gravity of the operation, which I hold to be considerable, and would lay stress upon Cases 22 and 51, which illustrate failure such as is probably inseparable from a certain proportion of all serious operations. Even short of the unhappy event of permanent stiffness, considerable trouble may be caused in convalescence by profuse secretion of synovia (Case 37) and by a tendency to stiffness of the joint (Case 23). Such cases cause great anxiety and require the most early careful and persistent treatment if a perfect joint is to be finally secured.

Grosvenor-street, W.

---

# A CASE OF ACUTE MYASTHENIA GRAVIS.

BY C. A. HINGSTON, M.D., B.Sc. LOND.,
CONSULTING PHYSICIAN TO THE PLYMOUTH PUBLIC DISPENSARY;
AND
W. H. B. STODDART, M.D., M.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER TO BETHLEM AND BRIDEWELL ROYAL HOSPITALS.

WE have thought it desirable to place the following case on record, partly on account of the rarity of the condition and partly on account of the fact that our case presented some unusual features

The patient, aged 71 years, was a contractor of Plymouth. He had lived a life of considerable mental and physical activity for about 30 years and during this time his health was above the average. At the age of 60 years he relinquished the greater part of his work; he became easily excited and fatigued and his business capacity obviously lessened At the age of 63 years he began to suffer severe neuralgic pains in various parts of his body and limbs, for which there was no apparent cause Finally, however, these pains became limited to the left leg and were sufficiently severe to confine him to bed for many weeks. At this time the urine was found to be of high specific gravity and to contain a considerable quantity of sugar. The glycosuria never quite disappeared, but it became so inconsiderable as to be scarcely appreciable by the ordinary tests.

About 12 months before his death albuminuria set in and continued to the end During the 12 months prior to his death he steadily lost energy and strength; but no local symptoms presented themselves till seven weeks before his death. He then relaxed his diabetic diet and his final illness appeared to date from this time. He developed a gradually increasing general weakness without malaise. He became exhausted during the process of dressing, the distance which he was able to walk grew daily shorter, and slight bilateral ptosis developed so that he was unable to read for any length of

## COUNTY ANTRIM INFIRMARY, LISBURN.

### TWO CASES OF SPINA BIFIDA TREATED SUCCESSFULLY—THE FIRST BY INJECTION OF MORTON'S FLUID AND THE SECOND BY EXCISION.

(Under the care of Mr. G. L ST. GEORGE.)

THE treatment of spina bifida by the injection of a small quantity of solution of iodine in glycerine was first practised by Morton, and its use was much extended by the strong recommendation which it received from the committee of the Clinical Society of London which was appointed in 1885 to consider the treatment of this malformation.[1] From our knowledge of the pathology we are justified in thinking that injections of iodine and glycerine can only effect a cure in a pure meningocele, and that it can do no good in a meningomyelocele or in a syringomyelocele. Since, however, it is rarely possible to decide with any certainty that no part of the spinal cord or its nerves is included within the sac, there is nearly always some risk in employing these injections, even if we do not consider the danger arising from a possible infection through the puncture. In consequence of this difficulty of diagnosis many surgeons at the present day are inclined to advise excision of the sac.[2] In this operation the two chief dangers are sepsis and the sudden escape of the cerebro-spinal fluid which may lead to grave disturbance of the circulation in the nerve-centres. The former danger may be guarded against by scrupulous care and for the latter the surgeon should avoid any rapid evacuation of the fluid. The operation of excision is applicable even in cases in which spinal nerves are contained in the sac, for they may be returned within the bony canal,[3] and such an aseptic operation must surely be safer than the indiscriminate injection of an irritant fluid. We congratulate Mr. St. George on his two successful cases.

CASE 1.—A female child, aged seven days, was admitted to the County Antrim Infirmary on Oct. 5th, 1901. She had a spina bifida of the fourth and fifth lumbar vertebræ. The tumour was of about the size of a small orange and was covered for about two-thirds by normal skin, but ended for the upper third in a membrane with a distinct margin. This membrane was beginning to show signs of ulceration. The tumour was markedly distended when the child cried or struggled, but there was no paralysis of the lower limbs or distension of the fontanelles. On Oct. 7th, the tumour having been thoroughly cleansed and made aseptic with sublimate lotion (1 in 2000) and the child having been anæsthetised with chloroform, Mr. St. George punctured the base of the tumour with a fine trocar, and after allowing about two-thirds of the contents to escape injected slowly a drachm of Morton's fluid through the cannula On withdrawing the cannula the opening was firmly grasped and painted over with *a solution of iodoform in flexile collodion* in order to close the orifice. The whole tumour sac having been painted with the collodion and iodoform it was covered with iodoform gauze and absorbent wool. The child seemed to suffer greatly from shock after the operation. The temperature rose to 103° F. and remained high for some days. On Oct. 21st the tumour was again tapped and some fluid having been drawn off the sac was injected as before and painted with the iodoform and collodion. The temperature did not rise on this occasion to any appreciable extent, nor did the child seem to suffer so much from shock, but there were great wasting of the limbs and constipation. She was therefore put on cod-liver oil and malt (Kepler) and Mellin's food. Under this form of food she rapidly improved in weight and appearance. The walls of the sac were now becoming shrivelled and more and more consolidated, except in the centre where a small piece of membrane still remained. On Dec. 21st, having again made the part aseptic, Mr. St. George dissected this piece carefully round expecting to find it communicating with the sac itself, but it did not do so; he therefore closed the flaps of skin over the opening so as to make a firm covering. The child did well and made a rapid recovery, *being shown at the meeting of the British Medical* Association (North of Ireland Branch) in Belfast on Jan. 23rd, 1902, and was discharged from hospital on Feb. 7th, only a fine cicatrix remaining. Unfortunately, no photograph was taken of this case before operation.

CASE 2.—A male child, aged three weeks, was admitted to the County Antrim Infirmary on Oct. 26th, 1901, suffering from a spina bifida of the seventh cervical vertebra. In this case the tumour was covered by skin completely. As the child was suffering from boils the operation was deferred for some weeks to allow of there being no chance of septic infection, as there was no urgency from the state of the

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

### DESQUAMATION

By J Reid M A., M D, C M Aberd

THE following notes may be of interest and they may lead to more searching inquiry on the subject of contagious diseases

CASE 1 —The patient a child, aged nine years when seen on Jan 8th had a typical measles rash with Filatow s and Koplik s spots Between the 17th and the 27th a brawny desquamation over the body was twice repeated with peeling of the skin of the hand and feet in large pieces

CASE 2 —The patient a woman 35 years of age, was suffering from pneumonia and subacute rheumatism when seen on Dec 29th From Jan 16th to the 22nd there was tonsillitis and from the 23rd to Feb 3rd there were present a brawny desquamation and free peeling of the hands and feet There was never any rash The rheumatism affected the joints the heart (transitorily) and various muscles There was neuralgia of the head None of the patient s children were affected, one had slight quinsy

CASE 3 —In the case of this patient whose age was 12 years tænia and ulcer of the leg were present The head of the tænia was not found An oleaginous preparation was applied to the ulcer on the leg On Feb 8th there was measles with Filatow s and Koplik s spots which was treated with carbonate of ammonia On the 9th there was perspiration in quantity under the oil at the site of the ulcer, the rest of the body was dry On the 14th there were lichen urticatus on the body and the back and erythema papulatum on the legs The itching from these was unbearable After the administration of a stomach mixture no trace of the rashes or itching remained next day On the 19th a brawny desquamation on the body and peeling of the hands and feet were the presenting conditions and on the 27th erythema on the chest and thighs was noticeable as well as some lichen on the back, but there was no itching and the tongue was clean There was no rash next day, but the peeling was nearly completed

CASE 4 —In the case of this patient, a child, aged five years who was seen on Jan 11th a bruit and rheumatism which had been left after an attack of scarlet fever six months previously were present On Feb 15th there was measles with Filatow s and Koplik s spots and on the 22nd a brawny desquamation commenced and there was afterwards extensive peeling of the fingers &c A brother of this patient aged one year, had on this date an irregular slight measles rash with Filatow s and Koplik's spots not followed by desquamation, and no trace of rheumatism exists

Other cases of measles had no desquamation and in all cases of desquamation observed there was evidence of rheumatism in some of the joints the severity of the case bearing no relation to subsequent desquamation Mixed affections in connexion with exanthemata have been little studied and out-of the way nerve lesions, &c, have been attributed to the fever How far the method of placing certain results among the effects of a fever plus a diathesis or latent disease deserves attention must rest on careful observation I have never seen desquamation follow measles in the tuberculous

Bristol

### RUPTURE OF THE COVERINGS OF AN UMBILICAL HERNIA WITH EXTERNAL PROTRUSION OF THE INTESTINE

By Frederick T Travers B S Lond, F R C S Edin,

SURGEON TO THE WEST KENT GENERAL HOSPITAL.

THE following case from its unusual nature may be worth recording The patient was a woman, aged 60 years who had a small umbilical hernia and had suffered for some years *from winter cough On Feb 20th, at 1 P M, she had a* rather more severe fit of coughing than usual and felt something give way in the abdomen She was seen at 1 30 P M by Dr F Voller who found that a mass of intestine was protruding through an aperture in the side of the hernial swelling Seeing that it was impossible to reduce it without operation and that this could not be carried out satisfactorily at her cottage he wrapped the extruded bowel in folds of warm cyanide gauze and, applying a temporary support by bandages ordered her to be removed immediately to the West Kent General Hospital at Maidstone This was a matter of some difficulty, as the patient weighed over 16 stones On arrival at the hospital she was suffering considerably from shock Ether was at once administered, and after cleansing the abdominal wall the gauze wrapping was removed and about six feet of small intestine were found to be protruding from a rent one and a half inches across in the side of an umbilical hernia The gut was irrigated with warm chinosol solution (1 in 2500) and was wrapped in warm sterilised towels The wound in the skin was enlarged till the bowel could be reduced A portion of omentum which was adherent to the interior of the sac was ligatured and cut away and the walls of the sac were freed and sutured The sides of the opening in the fascia were laced together by a continuous suture and after cutting out the portion of skin around the rent the wound was closed

After the operation which occupied half an hour, the patient s condition appeared to be better, she soon however began to run down again and she died from cardiac failure *38 hours later* There had been *no* previous ulceration over the point of rupture and the skin was not stretched and thinned out The sac and skin presented a considerable thickness and had torn linearly without any previous warning Doubtless the patient s extreme obesity and the accompanying loss of elasticity of the skin accounted for the occurrence of the accident

Maidstone

### GANGRENE OF THE SKIN DURING AN ATTACK OF ENTERIC FEVER

By Arthur S Barrow, M R C S Eng, L R C P Lond

A MARRIED woman was attended by me in May 1901 during an attack of enteric fever On the twenty sixth day of the illness there was severe hæmorrhage from the bowel which was repeated 12 hours later and the patient then passed into a typhoid state from which it was difficult to rouse her Two days after the hæmorrhage a small bulla appeared over the left outer malleolus and a large bulla over the right buttock in 24 hours the bullæ shrivelled up leaving a black patch beneath devoid of sensation The site of the bulla over the malleolus formed a slough which I removed leaving a punctiform ulcer one inch long by half an inch wide exposing the subcutaneous tissue The site of the bulla over the buttock formed a slough more gradually, but in 10 days from the appearance of the bulla I removed a large slough which left a deep excavated ulcer with sharply punched out edges one and a quarter inches deep three inches long and two inches wide The ulcer over the malleolus speedily healed although that over the buttock took longer but with the patient keeping the prone position a good result was obtained My patient never had a ' bed sore' and was very carefully nursed by a trained nurse

Indwe Cape Colony

---

**WORKHOUSE INFIRMARY NURSING ASSOCIATION** —This association which was founded in 1879 with the object of raising the standard of public opinion on the whole question of workhouse nursing of securing the appointment of trained ladies as matrons in all separate infirmaries, and of supplying nurses to workhouse infirmaries in London and the provinces has during the 22 years that it has been in existence received 1391 applications for nurses The number of nurses appointed has been 844 *On March 10th in the* Examination Hall Victoria Embankment London W C, Miss Gibson matron of the Birmingham Infirmary, read a paper entitled 'The Scarcity of Nurses in Country Workhouses, its Cause and Cure interest to find out how far down the nerve this regeneration extended. Certain it was that three months after section of the nerve it did not reach to the finer nerve branches in the muscle. If their view was correct that the nerve was regenerated by the neurilemma cells then it was difficult to see why regeneration should not take place in the finer nerves within the muscle just as it was stated to do in the trunk of the nerve. He would therefore like to ask the authors the following question, How far below the point of section had they traced the regeneration of fibres in cases in which the nerve had been completely divided?

Mr. **BALLANCE**, in replying, referred to a paper published in 1884 by Dr. C. S. Sherrington who had observed that regeneration took place on the peripheral side of the division of a divided nerve. Referring to the return of sensation after division he had often noticed that there was a preliminary return immediately after the operation, then it faded away, and then at the end of a week or 10 days it returned again. Referring to the operation for restoring the facial nerve the procedure suggested by Professor Langley corresponded with Faure's operation. But the best method was that of Manasse which consisted in suturing the facial into an opening of the sheath of the spinal accessory nerve *without injury to the actual nerve fibres of the latter.*

Dr. **STEWART**, in replying, agreed that the Golgi method was apt to be erratic, but when successful it gave all the information which they desired. The nerves had been examined as far as seven inches below the lesion and they had found identically the same changes. The essential fact of their paper was that regeneration occurred in a nerve fibre even when it was permanently cut off from its corresponding nerve cell. Now the neuron theory could not explain this. It did not fit the facts. It did not explain the absence of regeneration in the central nervous elements and its presence in the peripheral part. These facts necessitated a totally different view of function of the nerve cell. The purpose or function of the nerve cell was evidently to direct or to divert the nerve impulses, not to originate them. Thus the central nervous system was really a central exchange. The nerve fibrils were therefore the essential part of the nervous system; and the ganglion cells were only depôts or nerve shunts, so to speak. This, in point of fact, was the explanation offered by Apàthy and supported by Bethe, Nissl, and others. When an outlying nerve-fibre was cut off from the central exchange it was no longer functionally active and therefore degeneration set in. But the central part, which remained connected with its corresponding nerve cell or nerve shunt, still received impulses from other fibrils (through the cell) and did not degenerate. Later, even the detached outlying fibre was regenerated by the activity of the neurilemma cells and was ready to resume its function if linked on to the central nervous system. The essential elements of the nervous system, therefore, were the nerve fibrils. The nerve cells were accessories. But this was not the neuron theory.

## MEDICAL SOCIETY OF LONDON.

### *External Operation on the Larynx.—Gastrotomy for Recent Gastric Ulcer.*

A MEETING of this society was held on March 10th, Dr. F. **DE HAVILLAND HALL** being in the chair.

Mr. A. M. **SHEILD** read a paper on a series of cases of External Operation on the Larynx. Thyrotomy, he said, was an operation of considerable antiquity. The proper administration of chloroform was a factor of success. He advocated that the thyroid and trachea should be exposed by one longitudinal incision instead of making two operations as heretofore. He then proceeded to describe the operation which he was in the habit of adopting. It was generally done for actual or potential epithelioma. It was sometimes remarkable how well the patients recovered their voices. He then proceeded to narrate particulars of a series of cases. The first of these had been recorded in THE LANCET.[1] Another case was operated on for syphilitic stenosis, but the result was not favourable. In four other cases the operation was performed for various forms of neoplasm. The first of these was variously reported upon by three skilled pathologists respectively as papilloma, epithelioma, and a degenerated papilloma, potentially cancer; the next was a case of fibroma of the larynx; the third was a case of "warty papilloma"; and the fourth was a case of papilloma (though again the microscopists differed) which it was impossible to manipulate through the natural passages. In another case the operation was performed for a large foreign body. Mr. Sheild believed that this external operation had a great future before it, not only for malignant disease, but for other conditions unmanageable by way of the rima glottidis.—Dr. **DE HAVILLAND HALL** congratulated Mr. Sheild on the success of the case which had been exhibited before the society and thanked the patient for attending.—Mr. J. **HUTCHINSON**, jun., had assisted at a corresponding operation in 1879 performed by the late Mr. Adams. He was glad that Mr. Sheild had mentioned the failure of relief in syphilitic stenosis. He (Mr. Hutchinson) had just such a case under his care and he would not now think of operating. An important lesson from the paper was that malignant cases must be dealt with in the incipient—the so-called "pre-cancerous"—stage.—Mr. W. G. **SPENCER** referred to the difficulty which sometimes arose by the sudden supervention of difficult breathing in some patients. It was important to make the incision strictly *median in its symmetry, otherwise one cord might be injured.* He did not always think that it was an advantage to get primary union. Some cases of syphilitic stenosis could be operated upon with advantage, and cases were mentioned in illustration. He mentioned other conditions (other than those narrated by Mr. Sheild) in which he (Mr. Spencer) had performed thyrotomy. He advocated the median operation.—Dr. **STCLAIR THOMSON** thought that there was quite a future for this operation for growths in the upper parts of the larynx. However, cases in which thyrotomy was applicable were, he thought, relatively few. In syphilitic stenosis the operation was not suitable, but after a tracheotomy it was wonderful sometimes how the patients improved under iodide—far more readily than before the tracheotomy. He doubted the utility of the steam tent after thyrotomy; he had not found it useful. It was best to get patients up into a sitting posture.—Mr. **SHEILD**, in his reply, thought that possibly some cases of syphilitic stenosis might be suitable for operation. He did not generally advocate a preliminary tracheotomy in such cases provided the external wound was not closed too early. In cases of cancer of the larynx in which the glands of the neck were involved the disease was generally too far advanced for any operation excepting to relieve the dyspnœa. He quite agreed with Dr. StClair Thomson that cases requiring thyrotomy were relatively few.

Mr. C. W. **MANSELL MOULLIN** read a paper on three cases of Excision of Gastric Ulcer. Notes of the cases were read. In two of them the *operation of gastrotomy* with excision of the ulcer was performed for recurrent hæmatemesis, and in the third for persistent pain and vomiting. One of the former patients died on the ninth day after the operation, the gastric wound at the post-mortem examination showing little evidence of repair, being held together only by the sutures. The two others recovered completely. These, with those already published in THE LANCET,[2] made six cases of excision of gastric ulcer, five for hæmatemesis, with one death. It was usually held that the advisability of operating in these cases could be settled at once by comparing the actual mortality arising from hæmatemesis in cases of gastric ulcer with that which it was supposed might follow gastrotomy under similar conditions. But no such comparison was possible. On the one hand, the whole number of cases of hæmatemesis, trivial and severe alike, would be taken; while on the other hand, there would be only those cases which were absolutely desperate, in which the operation was performed as a last resource, after everything else had been tried and had failed. The only comparison that could be made with any fairness was between those cases in which surgical measures were advised and declined and those in which they were advised and accepted. If this were done there could be no doubt as to the results. In three of the five cases quoted the patients were already so bloodless that transfusion had to be performed, and in two others operation had to be declined altogether, as the patients were beyond even transfusion. The mortality of such cases left to themselves without operation would compare very unfavourably with that of *gastrotomy*, even when performed under desperate conditions. Mr. Mansell Moullin had asked Dr. R. C. B. Wall, the medical tumour. On Nov. 10th, the child being in good health, the tumour and surrounding skin were thoroughly cleansed and made aseptic and the child was anæsthetised. Mr. St. George made two horizontal flaps of skin, and having carefully raised them from the tumour down to the base, the tumour was punctured and fluid was allowed to escape. The base of the tumour was grasped with forceps and ligatured with catgut and the tumour was cut off. The skin flaps were then laid down and closed by a continuous suture of silkworm gut and all was dressed with iodoform and collodion and gauze. The child showed no signs of shock after the operation. The temperature rose on the 19th to 100 2° F. but never again above normal. The wound healed rapidly and the child was discharged on Dec. 16th, and was shown with the previous case at the meeting of the British Medical Association (North of Ireland Branch) on Jan. 23rd, 1902 The accompanying illustrations show the case before and after operation.

---

[1] THE LANCET, Nov. 14th, 1896, p. 1376.

[2] THE LANCET, Oct. 20th, 1900, p. 1125.

*Remarks by* Mr. ST. GEORGE.—The treatment of cases by Morton's fluid, though in the first case successful, is fraught with great danger and should be avoided if it be possible to operate by excision The injection of an irritating fluid into a sac communicating with the spinal canal must lead to serious consequences as evinced by the shock, &c ; whereas in excision with proper aseptic precautions the position of nerves can be carefully ascertained beforehand and avoided. However, it is not often that two cases showing the different modes of treatment can be so opportunely contrasted and the results compared.

# Medical Societies.

## ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

### *Clinical and Experimental Observations on the Regeneration of Peripheral Nerves.*

A MEETING of this society was held on March 11th, Mr. ALFRED WILLETT, the President, being in the chair.

Professor J. N. LANGLEY (Cambridge) resumed the discussion on the Regeneration of Peripheral Nerves. He remarked that the first and the principal point raised by Mr. C. A. Ballance and Dr. J. Purves Stewart in their opening paper was whether a nerve severed from its central connexions could become regenerated and by what means this was accomplished. In general he agreed that the distal cut end of a nerve could regenerate almost completely by itself, and he mentioned experiments and observations in support. It was, however, very difficult to distinguish for certain non-medullated fibres from strands of connective tissue, and thus unsuspected non-medullated fibres might possibly exist between the central and peripheral ends undiscoverable by the microscope. Histological observations were thus vitiated to a large extent ; but by other experiments he had come to the conclusion just mentioned. The degree of repair might be different in animals and in different kinds of nerves, and probably the peripheral end might not recover to the same extent as the central end As regards the actual manner in which regeneration took place, the view adopted by Mr. Ballance and Dr. Stewart was a new view, but it seemed to him to be perfectly reasonable. He was not, however, quite convinced about the neuroblastic formation of the nerve-fibre It was difficult in cut sections to follow nerve fibrils. It was necessary to tease specimens if it were desired to follow up the fibrils. The Golgi stain was erratic and osmic stains were preferable to the Weigert stain and the Golgi method. The essential point was that a peripheral nerve could regenerate apart from its central connexions. One point not cleared up by the opening paper was the rapid return of sensation in some cases of secondary suture. This might occur in from one hour to 24 hours, and if recovery of function did not correspond with structural regeneration how was it to be explained? He suggested as a hypothesis that the division of one or more nerve fibrils might happen just between two neuroblasts and thus the two in contact end to end might escape injury and being in anatomical continuity might transmit sensory impulses. In the surgical operations for the repair of a divided facial nerve it was usual partially to divide the spinal accessory nerve and to graft the facial on to the central portion of the spinal accessory. But he would suggest that it would be better to cut the spinal accessory quite across, to split it, and to unite one portion to the facial and the other portion to the peripheral cut trunk of the spinal accessory. He paid a high compliment to the thoroughness of the opening paper.

Dr. F. W. MOTT also agreed that nerves could regenerate from the periphery. In his own experiments he had cut both sciatic nerves so that the animal was completely paralysed and at rest. Now, the deposition of myelin depended largely on stimuli, such as muscular movement. This stimulus was therefore wanting in his own observations. He had used the method of teasing to trace the nerve fibrils in his specimens, and this was the only successful method. He illustrated his remarks by lantern slides, showing mitosis of the neurilemma cells and the absorption of fat. He discussed the various methods of staining and could not help regarding the Golgi method as a very unreliable one. The passage of a stimulus was, he believed, a very important one in the regeneration. He doubted if the authors of the paper had sufficiently tested the conductivity of the nerves which they had divided above and below the points of section with faradism. The experiments of Dr. Robert Kennedy of Glasgow had made it clear that regeneration of nerves took place from the periphery and this was confirmed by the researches of Mr Ballance and Dr. Stewart.

A contribution from Mr. A. W. MAYO ROBSON was read, in his unavoidable absence, by the Secretary. Mr. Mayo Robson reminded the society that at the first operation of nerve-grafting performed by himself in 1888 sensation to all the parts supplied by the divided median nerve was good when tested on the day following the operation and remained so, though the motor functions were not restored until later. He suggested that the immediate re-establishment of anatomical continuity of the nerve kept up physiological activity and so prevented degeneration of the distal segment He also referred to other cases.

Dr. W. ALDREN TURNER wished to comment on that portion of the opening paper bearing on the neural theory and asked, Must that theory be discarded? He believed not. There were too many data in support of it. There was not only Wallerian degeneration on the peripheral side and in the cut end of the central segment, but there were also changes which took place in the whole nerve trunk and in the spinal cord. These changes had not received sufficient attention in the paper of Mr. Ballance and Dr. Stewart. These observers stated: "New fibres never reach maturity until suturing is performed." This very statement went to support the neural theory. Turning to the clinical aspect of the subject, severe destruction of a nerve might occur with very little loss of sensation Probably a very few fibrils could supply a very large area of skin. Motion was very late in returning after secondary suture. Evidently the whole motor neuron was affected by section and not a small part of it.

Mr RICKMAN J. GODLEE, adverting to the surgical aspect, said that it was well known how quickly sensation was restored He also referred to the fact that pressure on a nerve produced disturbed function, as when lying on one's arm or leg. Esmarch's bandage might produce similar effects, lasting weeks or months. What were the changes which took place? Possibly it was an anæmia followed by reactionary congestion. For spasmodic tick he had in a good number of cases crushed the nerve by a pair of forceps, producing temporary paralysis. The nerve ultimately and completely recovered and the result had often been very satisfactory.

Dr F. E BATTEN said that while investigating the condition of the muscle-spindle after section of the nerve he had had the opportunity of examining the finer nerves at various periods after division of the sciatic. The operations had been performed by Dr. J. S. Risien Russell and the nerve had been stitched up so as to defeat any possible chance of reunion The nerves had been examined in the gastrocnemius muscle by the Marchi and Weigert-Pal methods at periods of three weeks, two months, and three months after section At three weeks the degeneration was marked, at two months there were still evidences of degeneration, and at three months also evidence of degeneration was still present, but at no period was there any evidence of regeneration of the nerve *Now it had been stated by* Mr. Ballance and Dr. Stewart that regeneration occurred in the stump of the nerve distal to the section. It would be of extreme large intestine about six inches in length, with immediate relief to the symptoms. The patient lived for nearly five months after this event, but finally symptoms of obstruction again appeared, and she died very rapidly. The abdominal tumour was found at the necropsy to consist of a large myomatous uterus and a large solid tumour of the left ovary, to the surface of which was attached what was probably a tubo-ovarian cyst of unusual size. Dr. Bonney remarked on the rarity of primary intussusceptions of the large intestine and the still greater rarity of their spontaneous expulsion. Intussusceptions occurring in persons over 50 years of age were very uncommon. The interest of the solid ovarian tumour centred around the relation between the tumour and its attached cyst, since outward inspection failed to decide as to whether the cyst was a very large hydrosalpinx which had attached itself to the tumour or whether the cyst formed an integral part of the tumour.

Dr. G. H. A. COMYNS BERKELEY showed a Uterus and Appendages removed from a patient who had died 12 hours after the termination of labour from acute peritonitis caused by rupture of an ovarian abscess. The patient, a multipara, had never suffered from any illness except an attack of pelvic inflammation which occurred before her marriage 10 years previously. The pregnancy had been uneventful. Intermittent pains commenced on Jan. 5th. On the 7th the pain became continuous and distressing and the patient began to vomit yellow fluid. Later in the day the labour terminated naturally, but the patient became rapidly worse and much collapsed, death occurring at the end of 12 hours. At the post-mortem examination purulent peritonitis was found to be present with a large amount of semi-purulent fluid in the abdomen. The right ovary and both tubes were healthy, but the left ovary formed an abscess sac which was bound down to the posterior surface of the uterus by old adhesions. There was an opening at the lower part of the abscess, through which pus was escaping. The abscess had also burst into the broad ligament and pus was escaping from an opening in that structure.—The case was discussed by the PRESIDENT, Dr. BOXALL, Dr. M. HANDFIELD-JONES, Dr. T. W. EDEN, Mr. TARGETT, Major H. R. WOOLBERT, I.M.S., and Dr. GRIFFITH.

## CHELSEA CLINICAL SOCIETY.

### *Discussion on the Nature, Origin, and General Principles of Treatment of Cancer.*

THE annual clinical debate of this society was held at the Jenner Institute of Preventive Medicine, Chelsea-gardens, S.W., on March 11th, Dr. C. A. MORRIS, C.V.O., the President, being in the chair.

The PRESIDENT, after a few opening remarks, called upon Dr. JAMES GALLOWAY to open the debate on Cancer, its Nature, Origin, and General Principles of Treatment.

Dr. GALLOWAY said that the present was a good occasion for a revision of the additions to their knowledge on the subject of cancer made during the last eight or 10 years. Renewed investigations were being actively undertaken to solve the great pathological problem of the origin of the disease with every prospect of encouragement and it was well to appreciate the exact state of their pathological knowledge. The last great stimulus to investigation on the subject was the enunciation of the thesis of the parasitic origin of the disease and most of the researches of the last decade had been made as a consequence of this proposition. It must be admitted that the foundations of this hypothesis had been gradually weakened, unfortunately with a corresponding diminution in the activity of researchers. There could be no two opinions that their knowledge of the nature and development of cancer and also of its treatment had much advanced as the result of the investigations to which he had alluded, in spite of their apparently fruitless nature at the time. He hoped that new investigations would add still more to their knowledge of the origin of the disease. Speaking of other hypotheses of the origin of cancer, Dr. Galloway said that they had also been of assistance in advancing their knowledge. Little had been added to strengthen the theory upheld by Cohnheim that tumours were due to the abnormal and late development of remnants of embryonic tissue. As a general explanation the accumulated evidence was much against this hypothesis. That Cohnheim's hypothesis explained the origin of certain varieties of tumours which were perhaps more of the nature of deformities had always been recognised, and recent work as to the development of certain forms of epithelioma from remnants of developmental tissue in nævi had allowed to some extent of its wider application. Unfortunately, the identity of the actual cause of the growth of these tumours originating from nævi was not discovered, and the reason of their assuming malignant characters, the most important of all questions, was not explained. Cohnheim's explanation especially failed in attempting to account for the characters of malignant growths. A certain amount of knowledge had also been obtained by the recognition of the fact that epithelial cells, accidentally transported into tissue of different nature, were capable of multiplication and of the formation of new epithelial masses. The "implantation cysts" described in the eye and certain masses of epithelium in the corium occurring as the result of injury were examples of this process. This new epithelial tissue reproduced the characters of the cells of the region whence it was originally derived; but in cases where malignant features had been assumed they were as much at a loss as ever in accounting for this additional characteristic. A point of the greatest importance to be recollected was that the dangerous attribute of the malignant tumour was not simply the power of multiplication possessed by its cells, but the fact that the cells undergoing multiplication did not content themselves by remaining in their normal position and relation to surrounding tissues within their basement membrane in the case of carcinoma, but consisted of the power which they assumed of passing beyond this limit and of invading the neighbouring tissues where normally they ought not to exist. The malignant element did not consist in the overgrowth but in the assumption of this new power of invasion. Considering next the parasitic hypothesis of the causation of cancer, Dr. Galloway remarked that none of the structures described as parasites of protozoal nature in carcinoma and sarcoma had withstood the test of criticism and could now be reasonably considered to be protozoal parasites. Analogies had been made, which at one time promised important information as to the cause of cancer, between certain diseases characterised by overgrowth of tissue in the lower animals, and undoubtedly due to protozoal infection, and the peculiar overgrowth of tissue which occurred in cancer, but these had turned out to be less informing than had been hoped. One of the most interesting of these was the infection of the liver in rabbits by the coccidium oviforme, which resulted in the appearance of nodules in the course of the bile-ducts consisting of an adenomatous overgrowth of their epithelial lining. But although there was much increase of epithelium in these nodules the epithelium was arranged in the normal fashion, and although the lining membrane became elaborately convoluted the epithelial cells did not overstep their limiting membrane and never assumed malignant characteristics. Indeed, it might be fairly asked whether the intracellular or extra-cellular position of the coccidia directly produced multiplication of the epithelial cells, or whether this multiplication was not rather due to irritation of the epithelium produced by obstruction of the ducts by the parasites and should be considered as a secondary consequence of their presence. A very important point arising from the study of these protozoa was that they were very readily recognised; there could be no question of their existence even on simple microscopical examination, while their processes of reproduction could be readily watched. If they were removed from the liver while living and kept in a moist atmosphere their protoplasm might be seen to divide and the various stages of multiplication external to their host might be readily observed. In none of the supposed protozoal structures seen in cancer had vital changes of this nature been clearly demonstrated. It was noticeable at the present time that observers were inclined to attribute to certain budding fungi a causal rôle in the production of cancer. Two great difficulties stood in the way of accepting this theory—namely, in the first place, that similar bodies had been discovered and had been claimed to be the causative elements in a class of diseases of which the origin, development, and structure were totally different from cancer—namely, the granulomata. Pathologists were familiar with the writings of authors who had described cases of blastomycosis or blastomycetic dermatitis. Some of these observers claimed that the yeast-like fungi which they had found to be present were the actual cause of lesions which in many respects resembled tuberculosis. Of these observations some would not now be claimed to lead to the conclusions originally stated by their authors, but granting that some of the observations and conclusions were to be accepted as correct it was very difficult to believe that similar parasites were on the one hand capable of producing egistrar at the London Hospital, to tabulate for him the tatistics of all the cases of hæmatemesis from gastric ulcer which had been admitted during the five years 1895 to 1899. The total number was 246—202 women and 44 men. Among he women there were only four deaths. Three of these deaths occurred, however, in the 49 women who were over 30 years of age, so that the mortality in women under 30 years of age was less than 1 per cent., while in those over that age it was [illegible] per cent. In the men, on the other hand, taking all the ages together, the mortality from hæmatemesis alone was 14 per cent. When the other causes of death in gastric ulcer were taken into consideration it must be admitted that the death rate due to gastric ulcer, especially in the case of omen over 30 years of age and in men, was very much higher than was usually believed. There was no doubt that he main treatment of gastric ulcer was and must remain in the hands of physicians, but as had been already recognised n the case of perforation it was equally clear that certain contingencies or accidents might arise which could only be met by the adoption of prompt and decisive surgical measures. So far as hæmatemesis was concerned it was clear hat much greater risk could be run in the case of women under 30 years of age than in the case of those over that age and especially in the case of men. But if due allowance were made for this it might be laid down as a general rule that if there was one single severe hæmatemesis in a case in which the previous history suggested the presence of a chronic gastric ulcer (for in this case the bleeding had probably been due to an opening in an artery of some size) or if there had been two separate attacks of severe hæmatemesis at a short interval, or if there were frequent small hæmorrhages so that the patient was becoming seriously anæmic, there was less risk in operating than in leaving the patient to the chance of the hæmorrhage stopping of itself.

# OBSTETRICAL SOCIETY OF LONDON

*Suppression of Urine after Labour.—Sarcoma of the Ovary.—Exhibition of Specimens.*

A MEETING of this society was held on March 5th, Dr. PETER HORROCKS, the President, being in the chair.

Dr. R. G. McKERRON read a paper on Suppression of Urine after Labour. He at first directed attention to the fact that suppression of urine before and after labour was rare notwithstanding the frequency of pathological changes in the kidneys during pregnancy. From recent experience he was *disposed to believe that as a puerperal compli*cation complete or partial suppression was more common than the small number of recorded cases would suggest. He described three cases which came within his own knowledge, adding short abstracts of three cases of complete anuria found in literature. The causation of anuria after labour was obscure. To assist in the solution of the causal problem an analysis of the leading clinical features of the cases was given, from which Dr. McKerron concluded that several factors were concerned in its production and that these might be variously combined in different cases. The essential causes he believed to be—(1) a nephritis similar to that underlying eclampsia and probably superimposed on kidneys previously defective; *(2) a neurotic temperament; and (3) shock resulting from* precipitate labour or from intense pain accompanying its progress. The paper concluded with a few observations on treatment and on the possible effect of opium in contributing to the suppression.—Dr. R. BONNEY presented the details of two cases in which partial suppression of urine occurred, in one after labour and in the other after a miscarriage in the fifth month. In both cases the patient died and in both disease of the kidneys had previously occurred. Except for persistent vomiting till shortly before death there were no marked symptoms indicative of the grave condition of the kidneys. In the first case the urine was examined soon after labour and active measures, which included saline injections into the bowel and into the veins, were early adopted, but unfortunately these measures failed to re-establish the functions of the kidneys.—Dr. W. GRIFFITH said that there appeared to be two classes of puerperal cases of suppression of urine, one being the common cases of acute nephritis with or without eclampsia, and the other very rare and quite unconnected with this disease. He had seen one of the latter some years ago. The patient was a primipara who was quite clear in her mind, without headache or uræmic symptoms, and with complete suppression of urine; she survived about five days and the treatment adopted failed completely. His recollection of the case was that it was a complication of acute septicæmia.—Dr. W. MURRAY LESLIE *said that he could recall three* cases where, however, the anuria did not prove to be complete, though the daily amount of urine voided was in excessively small quantities and loaded with albumin, and in each of these cases the main factor in setting up the condition proved to be alcohol. The first case seen in consultation had a long history of indulgence and ended fatally after a fortnight with uræmic symptoms. The patients in the other two cases in private practice—primiparæ—recovered. These two latter patients had never been previously suspected of alcoholism, and one had only acquired the habit during the pregnancy. The kidneys were not examined as post-mortem examinations were not obtainable. He emphasised the importance of regular examination of the urine at intervals during the latter part of a pregnancy and of dealing firmly with the question of alcohol should any trace of albumin be found to be present.—Dr. W. W. H. TATE referred to a very remarkable case reported by Bradford and Lawrence in the *Journal of Pathology and Bacteriology* in May, 1898. The patient, a multipara, was delivered of a stillborn child on Feb. 28th, 1896. She was sick after the confinement was over and suffered from headache and slight drowsiness. She said she passed no urine from the time of her confinement until March 2nd, when two teaspoonfuls of urine were drawn off. There were no fits or twitchings; the patient gradually became worse and she died suddenly on March 7th. At the necropsy there was found to be necrosis of nearly the whole cortex of both kidneys. There was widespread endarteritis of the interlobular arteries which were thrombosed and had caused necrosis of the convoluted tubules throughout the cortex. Dr. Tate also reported the following case of anuria following labour. The patient, a primipara, passed through a normal confinement on April 16th, 1899. All went well till the 23rd, when, while having a vaginal douche, the patient had a shivering attack and her temperature rose to 102·5° F. She felt faint and vomited. *On the same day* she complained of sore throat. On the following day the temperature had fallen to normal but she vomited four times during the day. On the 25th at 6 A.M. she began to hiccough and this troublesome symptom continued until death. There was also some diarrhœa. The lochia appeared to be healthy and free from odour. The amount of urine passed was first observed to be below the normal on this day. On the 26th Dr. C. J. Cullingworth saw the patient and curetted the uterus. *On the 28th the hiccough still continued*, the temperature was subnormal, and still no urine had been voided. The patient died suddenly at 6.30 P.M. She complained of sudden pain over the heart and died before the nurse could get to the bedside.

The report of the Teratological Committee upon Mr. Stannus's *specimen of Orbital Tumour in a Fœtus* was read.

The PRESIDENT showed Two Sarcomata of the Ovary, each tumour being of the size of a football. They were removed recently from two patients who presented almost identical symptoms—namely, a large, freely moveable solid tumour together with abundant ascites (necessitating paracentesis in *one case to relieve dyspnœa*), marked wasting, pyrexia, and pleurisy. The latter was thought to be due possibly to secondary growth. Both patients were making a good recovery. It was interesting to note that in one case the small intestines were so intimately adherent as to require a very careful dissection, whilst in the other case there were no adhesions. In the former the sarcomatous elements were most abundant, whilst in the latter the fibrous element predominated. *Both women were multiparous*, the one with the marked sarcoma was under 30 years of age and the other was about 40 years of age.—A discussion followed in which Mr. J. H. TARGETT, Dr. A. CORRIE KEEP, Dr. W. F. VICTOR BONNEY, Dr. TATE, and Dr. AMAND J. M. ROUTH took part.

Dr. TATE having shown a specimen of a Lithopædion, the PRESIDENT and Dr. A. L. GALABIN commented upon the case.

Dr. BONNEY showed two specimens from a patient aged 50 years who had suffered for 12 years from an Abdominal Tumour of large size. Last October she was seized with symptoms of subacute intestinal obstruction and subsequently she spontaneously passed an intussusception of the

It was notorious that in recent years the mortality from cancer had increased very rapidly, not only among females but among males. This was shown by the subjoined figures :—

*Annual Rate of Mortality in England and Wales: Rate per Million Living.*

| Males. | | Females. | | Increase in 1891–1900 per cent. | |
|---|---|---|---|---|---|
| 1861–1870. | 1891–1900. | 1861–1870. | 1891–1900. | Males. | Females. |
| 242 | 597 | 519 | 903 | 147 | 74 |

It thus appeared that although at the present time women suffered much more severely than men from malignant disease, nevertheless the disease during the last 30 years had increased among men much more rapidly than among women.

Dr. G. T. BEATSON (Glasgow) said that they must not lose sight in a discussion of the kind they were engaged in of the subject of tumour formation as a whole, and any theory explaining only one neoplasm was, in his opinion, defective and unsatisfactory. In regard to that there were one or two statements that he thought should be discussed at that time. They must remember that there was undoubtedly a connecting link between malignant and benign growths. This arose from the fact that being composed of the tissues of the body these have all had a common parentage They have all sprung from two epithelial cells, from a male and from a female cell, and these were to all intents and purposes epithelial cells. As a consequence of that, no matter what the ultimate history of a cell might be, it had had in one time of its history an epithelial form. The character of the cell might be altered and the differentiation might be slight in some and in others it might result in the formation of tissue of the highest type. These differentiated tissues as long as they retained their specialised form "bred true"—that is to say, an epithelial cell produced an epithelial cell and a connective tissue cell produced a connective tissue cell. Differentiation lessened the proliferating power of cells and daily proof of that was seen in the amount of regenerative power shown in wounds and injuries, whilst regeneration took place copiously and freely in the lower tissues like epithelial tissue, while those of a higher type like muscles could scarcely be reproduced. Certain facts seemed to show that this differentiation only masked the epithelial type to which he had referred. Less highly specialised cells might revert to their primitive epithelial form, and in no other way could they explain the well-known fact that benign tumours might become malignant. If a benign tumour could become malignant, if it could revert to a lower type, they must not deny to the tissue which it represented the same power. If the influence or influences that caused tumour growth came into play the effects would vary with the tissue involved. If it was a highly specialised tissue they would have a limited growth—i.e., a benign tumour; if the tissue attacked was very little differentiated then they would have an indefinite growth, with great proliferation—that is to say, a malignant tumour. The proliferating power was to be measured by the amount of specialisation to which the cells had attained or which they possessed at the time of the attack, because they might have degenerated. They had then in the body always present a proliferating power in the cells that varied with the natural differentiation of the tissues that might be lessened in amount. The tissues might be thus brought to a lower standard with a consequent increase of proliferating power. That was one factor in tumour growth and the other factor required was the necessary stimulus. Before he discussed that he would like to draw attention to the similarity that existed between cancerous and early embryonic tissue. In the body the tissues that were formed at first were similar in structure to those in cancerous growths, and it was only in connexion with that embryonic tissue and its power of development that they had anything at all approaching the proliferative power of malignant tumours. In connexion with embryonic development there had also to be noted the relation of malformation to neoplasms. Uniovular twins depended on a pathological process, and this was also the case in joined twins, in children with extra limbs or incomplete bodies attached, in children with sacral tumours of fœtal tissue, and in children with dermoids. All these various gradations formed a complete series. Dr. Beatson, after expressing his belief in the local origin of cancer, passed on to the consideration of the factor or factors that started local cell proliferation or the causes of tumour formation. A natural division was into causes from without and those from within. Of those from without the parasitic theory was the only one that required notice. This theory was supported by the discovery of the so-called cancer bodies but the fatal objection to that view was found in the consideration of the conditions observed in congenital tumours and in secondary growths. Another difficulty in this connexion was the absence of toxins. He believed in an intrinsic cause that explained the commencement of local cell proliferation which was based on the results observed in oöphorectomy for mammary cancer. The chief interest in this operation lay in the fact that after its performance there had been a disappearance of cancerous tissue. Others besides himself had obtained that result and various explanations had been given of the circumstance. It had been suggested that it was because of diminished vascularity of the parts, also that the cause was from an increase of resistance on the part of other cells in the body, and another view had been put forward that the effect was due to the opening of the abdomen. In his opinion, however, the above reasons were quite inadequate and he considered that a more potent factor must be sought. He believed that the explanation was to be found in the facts connected with the testes and ovaries. In his original paper he had suggested that these organs might be the exciting cause of cancer in two possible ways, but a third possible explanation was to be found in what happened in connexion with the function of the testes and ovaries. Both these organs had to prepare cells to perpetuate the species; the testes did this by forming spermatozoa out of epithelial cells, the ovaries did it by carrying out those maturation phenomena which enabled certain of the epithelial cells contained in them to perform the function of fecundation. By what agency was this done and what was the stimulus that caused the cellular division in the testes and the cellular activity in the ovary? In his opinion it must be a secretion of some kind, and that being so, where was it elaborated? Was it secreted by the organs themselves or by all the tissues of the body under the stimulus of these organs, or were such organs the instruments for ratifying the work done by the rest of the body? In other words, was the fructifying fluid that gave to the spermatozoa and the female ovary their procreative power the product of the whole of the body and not a local manufacture? Such a view was not altogether unsupported by facts that had been observed in connexion with the thyroid gland and in regard to the subtle influences that the testes and ovaries exerted on the general nutrition of the body. There had also to be considered the profound impression made on the whole fabric of the body by the removal of these organs which was seen in the case of eunuchs and after oöphorectomy. What was the actual relationship between the rest of the body and the testes and ovaries, supposing the condition to be as he suggested? When these organs dwindled with age or became functionless what happened to this body secretion? Did it dwindle also under the lessened influence of these organs ceasing entirely to be given up on their removal or complete atrophy? or did it continue after they were functionless and be then again taken up by the tissues themselves? There was the further problem as to when those organs lost entirely their influence over the functional activity of the body. The impossibility of answering these queries rendered reliable conclusions difficult, but the facts, however, seemed to point to the tissues ceasing to give up this fluid on the removal of the testes and ovaries. They were now in a position to judge what bearing these views had on the causation of the cancerous process. He need hardly point out that the existence of such a fructifying fluid in the body tissues furnished an explanation of many observed facts and opened up also other possibilities. It was of the greatest importance in connexion with cell proliferation and tumour formation. It furnished the factor that was alone wanting to explain the case, for, as they had seen, the tissues already possessed in varying degree the power of cell division or proliferation. If it were granted that such a fluid existed in a granulomatous tumour and were also capable of producing such a totally different growth as a carcinoma of the breast or other glandular organ. In the second place, it was very probable that new growths, including the carcinomata, might be infected occasionally, though rarely, and probably accidentally, with certain fungi producing both hyphæ and spores. These fungi apparently grew readily when introduced into the tumour and in all probability were capable of cultivation outside the body. But it would be unjustifiable to form the conclusion that the fungus found to be present was the cause of the cancerous tumour. If in such a case a culture of the fungus was obtained and inoculated into a susceptible animal and proved to be pathogenic it was much more easy to believe that the growth which would appear as the result of inoculation would have the characters of a granuloma rather than of a cancer. It was from their clinical experience that they were all likely to inquire as to the truth or falseness of a pathological theory, and it must be admitted that clinical evidence gave but grudging and very scant support to the parasitic theory of the origin of cancer. There was a very interesting body of clinical evidence which had not been greatly appealed to as yet in considering this question derived from those diseases in which prodromal morbid states, it might be for years, preceded the development of cancer. In Paget's disease of the nipple they had a prodromal state preceding the development of cancer. But according to the evidence of some observers the prodromal state was in this case too nearly allied to cancer itself to furnish a good example. These authors would call Paget's disease by some such name as "malignant papillary dermatitis." He referred particularly to such conditions as in xeroderma pigmentosa and to certain forms of abnormal pigmentation. In both of these conditions there occurred, possibly for years before the development of a form of carcinoma which proved fatal, an alteration in the texture of the integument. In the case of the former this change was characterised by the development of pigmentation resembling exaggerated freckles and accompanied by atrophy of the skin. In the case of the latter melanin was deposited in such abnormal positions as in the clefts of the fingers or toes, or about the nails, in localised areas with clearly marked margins. It was surely more easy to conceive of these changes as being successive manifestations of a progressive process of degeneration, the earlier signs being alteration of the pigment distribution and the later the disorganisation of the means by which the growth of the epithelium was kept in check and properly distributed and arranged. And if it was conceded that the distribution of pigment was very directly influenced by the nervous system, might not the process continue and the disorganisation of nervous control end in allowing the resistance of the connective tissues to be impaired and the epithelium to escape from control? So, also, in the prodromal conditions, of which senile keratoma was an example, from which arose epithelial cancers of varying degrees of malignancy, was it not an easier conception to hold that the whole course of the disease was continuous than to invoke the action of a parasite when at last the epithelial cells were so affected as to show evidence of the peculiar form of overgrowth which was recognised as "malignant"? Considerations such as these led to discussions on the subject of the "physiological equilibrium" of the tissues and its alteration in disease so interestingly placed before them by Dr. C. P. White in his Erasmus Wilson lectures, but such discussions at the present time were very fruitless because they did not know the factors which maintained and interfered with this condition. It must be the desire of everyone that observation and experiment would in the near future tell them why the balance was upset and why a tissue cell, instead of leading its normal life, suddenly ran riot, penetrating beyond bounds, and multiplying with an energy never approached in its usual normal well-ordered existence.

Dr. JOHN F. W. TATHAM (superintendent of statistics, General Register Office) said that in England and Wales during the last four years the deaths from malignant disease had averaged more than 25,000 a year. In the returns issued from the General Register Office the term "malignant disease" included all the diseases classed as such in the nomenclature of the Royal College of Physicians of London. Hitherto all forms of malignant disease had been grouped together under one heading in their national returns, but with the new century a revised list of diseases had been inaugurated, of which a shortened form was published for London in the weekly return from which he quoted. The table showed that the carcinomata, or true cancers, were distinguished from the sarcomata, and these again were distinguished from the indefinite forms of disease which were ascribed in medical certificates to "malignant disease," or "cancer" merely without further qualification. That medical practitioners appreciated that improvement in the classification of a most important group of diseases was shown by the fact that in London since the beginning of the present year, when the new list of diseases was first published, the deaths from malignant disease, in the aggregate rather more than 800 in number, had been differentiated; thus, in the medical certificates supplied for registration 52 per cent. had been certified as from carcinoma, 6 per cent. from sarcoma, and the remainder, amounting to considerably less than half, to "cancer" or malignant disease. It was highly gratifying to him, as he was sure it would be to them, to note how readily the practising members of their profession had responded to any attempt to secure greater accuracy in the statistical records of the fatal cases coming under their care. He took the opportunity of cordially thanking many of the physicians and surgeons present for the courtesy and kindness with which they had invariably answered his requests for fuller information respecting deceased patients than that which could be got into the ordinary form of certificate. Malignant disease in the aggregate—i.e., without limitation as to organ or part affected—was more fatal to women than to men. According to the latest returns the male death-rate from cancer in England and Wales was equal to 672 in each 1,000,000 living, whilst the female death-rate amounted to not less than 975 per 1,000,000. But this excess was due to the unequal tendency of malignant disease to attack the generative organs of the female than those of the male. On reference to the following table it would be seen that when the deaths from cancerous affections of the ovaries, uterus, and breast were subtracted from the total cancer deaths of females, the remainder gave a death-rate among females which was considerably below that among males. Thus, in the four years 1897–1900 the male deaths from cancer less the deaths from disease of the organs referred to corresponded to a death-rate of 645 per 1,000,000, whilst the female rate with the same limitations did not exceed 568 per 1,000,000.

*Cancer Mortality, 1897–1900: Total Deaths in the four years 102,685.*

| Parts affected. | Deaths. | | Rate per 1,000,000 living. | |
|---|---|---|---|---|
| | Male. | Female. | Male. | Female. |
| All parts ... ... . ... ... | 40,317 | 62,368 | 657 | 952 |
| Lip .. .. ... ... ... | 647 | 74 | 11 | 1 |
| Mouth ... ... .. . ... | 508 | 115 | 8 | 2 |

| Stomach .. .. | 8,369 | 8,355 | 136 | 127 |
| Intestines . . . . | 6,312 | 6,731 | 103 | 103 |
| Liver . .. | 5,532 | 8,654 | 90 | 132 |
| Generative and mammary organs ... | 726 | 25,151 | 12 | 384 |

The mortality from cancer was not very excessive until some time after the twenty-fifth year of age. Thus at ages under 35 years it averaged from 44 to 66 per 1,000,000, but as age advanced the mortality increased in both sexes very rapidly until at the more advanced ages it was enormous. The following table showed that.

*Cancer Mortality at Certain Ages, 1900.*

| — | Annual death rate per 1,000,000 living at each age. | |

bones, and, if so, whether such growths partook of the histological character of the thyroid itself.—Mr. DANIEL, in reply, said that the skin was not pigmented. He showed a specimen in which there were secondary nodules affecting both lobules of the thyroid. With the exception of the spine in one case there had been no tumour of bone or lung in any of the cases, although the walls of the subclavian vein were undoubtedly involved. On section the new growths in the spine were seen to be simply pure sarcomata.

# EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*Meralgia Paræsthetica.—The Relative Inefficiency of Cacodylates as Therapeutic Agents.—The Coordination of Medical Research in Edinburgh.—Exhibition of Cases and Specimens.*

THE seventh ordinary meeting of this society was held on March 5th, Professor T. R. FRASER, the President, being in the chair.

Dr. EDWIN BRAMWELL showed a case of Meralgia Paræsthetica (Bernhardt's Sensibilitatsstörung). The patient, a miner, aged 43 years, for 18 months had suffered from pain over the right hip and over the lower part of the right thigh anteriorly, also from a feeling of coldness on the outer side of the right thigh. The pain was greatly increased by walking and was so severe that it had incapacitated him from work. In other respects he enjoyed excellent health; he had not had rheumatism or syphilis The condition was attributed to sleeping on hard boards in damp clothes. Upon examination an area of relative cutaneous hyperæsthesia was found on the outer side of the right thigh, while there was marked tenderness on pressure over a point one and a half inches below and just external to the right anterior superior iliac spine. An exhaustive examination failed to elicit any other objective signs of disease; the patient's symptoms were obviously referable to the right external cutaneous nerve. Since no improvement resulted from rest in bed and faradism Dr. H. Alexis Thomson cut down upon the nerve at the level of Poupart's ligament and excised three inches. The nerve and its relations appeared to be normal. As an immediate consequence of the operation the pain which had previously been present, even when the patient lay in bed, disappeared. Dr. Bramwell showed photographs to illustrate the area of anæsthesia produced by division of the nerve. For two or three weeks after the operation the patient complained of a feeling of tenderness on deep pressure over this area. Four weeks after the operation he was quite free from pain but still had a feeling of stiffness about the front of the right thigh. The excised nerve was placed directly in 5 per cent. formalin. No degenerated fibres were to be seen in sections stained by Busch's method. Sections taken from pieces of the nerve hardened in chrome alum did not stain with Weigert's method: Was this to be accounted for by the fact that the nerve had been taken from the *living* body and placed directly in formalin? Dr. Bramwell considered meralgia paræsthetica to be a distinct clinical entity, probably not uncommon, Roth having recorded 15 personal observations. The condition was well worthy of notice for purposes of exclusion in differential diagnosis, while cases occurred where the pain was so severe as to unfit the patient for work. The pathology was obscure. It might be that in some cases it was merely a neuralgia, in others a neuritis. Faradism appeared to have been efficacious in the treatment of several of the reported cases. Resection of the nerve was only justifiable in severe and persistent cases.

The PRESIDENT read a paper entitled, "The Relative Inefficiency of Cacodylates as Therapeutic Agents," with lantern illustrations. He stated that compounds of cacodylic acid [As $(CH_3)_2O(OH)$] had of recent years been largely used as substitutes for the commoner forms of arsenical compounds. It was asserted that new preparations had certain advantages over the older preparations of that element which were usually employed. A considerable amount of clinical experience had already been accumulated regarding the actions of several of the cacodylates, especially that of sodium and iron. The cacodylate of sodium had been administered in almost every disease where the ordinary preparations of arsenic had been usually employed—as, for example, anæmia, leukæmia, pseudo-leukæmia, many skin affections, phthisis, leprosy, bronchitis, chorea, and neurasthenia. Almost everyone who had experimented chemically with the cacodylates had expressed themselves most favourably with regard to their value.' Dalché of Paris stated that of 11 cases of pulmonary tuberculosis treated with sodium cacodylate injected subcutaneously three patients were undeniably cured, four were greatly improved, two showed no results, and two (very advanced) became worse. Dr. Anelli had described a case of severe pulmonary tuberculosis in which remarkable success was attained by the intravenous injection of 0·8 grain daily. Rocax treated 80 cases of tuberculosis and stated that except in very advanced cases the cough, night-sweats, and pyrexia disappeared in cases of pulmonary tuberculosis and that the body weight was increased. He made the remarkable statement that in cases of "latent, suspected, or threatened tuberculosis cacodyl triumphs." Gallois, who had given sodium cacodylate by the mouth, claimed that chronic bronchitis with asthmatic paroxysms of elderly people was the disease which was chiefly benefited by the new drug. Ewart noted the "brilliant effects [of cacodylates] in all cases where arsenic was indicated, especially in chorea, malaria, pernicious anæmia, and Basedow's disease; also in the hectic fever and the cough and expectoration of phthisis, and in all nervous exhaustions.' Bormans summarised his experience with cacodylate of sodium as follows: "It is a remedy which may be tolerated in much larger doses than those usually given and therefore is valuable in all cases where large doses of arsenic are indicated, as in anæmia and chlorosis, especially where iron is not tolerated. Burlureaux had good results in neurasthenia and chlorosis, Doulos in pseudo-leukæmia and psoriasis, and Reynard in psoriasis, lupus erythematosus, cutaneous tuberculosis, sarcoma of the skin, and leprosy. Gautier stated that the salts of cacodylic acid did not act in any special disease but in all weakened conditions, and the success was the more remarkable in that it was free from risk. He stated that the daily quantity of subcutaneous injection was 0 05 gramme, equal to 0·37 grain of arsenicum, or 51 minims of liquor arsenicalis. The President pointed out that the employment of cacodylates was based on the supposition that these compounds, though rich in arsenic, were almost inert, and so large quantities of arsenic might by their use be introduced into the body with safety and advantage, but he thought that if they were not capable of causing toxic effects when given in quantities relatively far larger than those of the usually employed compounds of arsenic, they must to a corresponding degree be pharmacologically inert and therapeutically inefficient. To test this opinion he had administered cacodylate of sodium and cacodylate of iron in several of those diseases where arsenic was commonly employed. Taking first the disease chorea, in which the value of preparations of arsenic had been abundantly proved, cacodylate of sodium was given to three patients with the following results:—

CASE 1.—The patient was a girl, aged nine years, ill for 10 days, who was treated for 45 days. The minimum and maximum doses were three quarters and four and a half grains in 24 hours. As there was no improvement liquor arsenicalis was substituted in doses varying from nine to 12 minims in 14 hours. In seven days marked improvement was noted, and in 10 days no choreic movements were present.

CASE 2.—The patient was a boy, aged nine years, ill for four weeks, who was treated for 23 days. The doses of cacodylate varied from three quarters of a grain to 11⅓ grains. After 20 days improvement began, when the dose was seven and a half grains in 24 hours, and continued so until recovery, which was delayed by diarrhœa.

CASE 3.—The patient was a boy, aged 13 years, ill for 10 days, who was treated for 52 days, the daily dose varying from one and a half grains as a minimum to 10½ grains as a maximum. There was hardly any improvement until the twenty-eighth day and then very slight until the fifty second day. On the substitution of liquor arsenicalis in doses of from six to 12 minims per diem there was a marked improvement in seven days; this was great in 14 days, and he had entirely recovered by the twenty-first day.

In one case of acute eczema affecting the whole surface of the body except the scalp cacodylates were tried. During 17 days previously to this drug being given material improvement with disappearance of the acute symptoms had occurred under mere regulation of diet, purgatives, and exalgine Sodium cacodylate was given for 23 days and then intermitted for four days because of nausea and vomiting and again given for other two days. There was slight improvement in the skin condition in six days and this continued gradually. The dose varied from three to 15 grains in 24 hours. One case of spleno-medullary leucocythæmia was treated with sodium cacodylate for a period of 12 days with doses of from one to three grains in 24 hours. Neither in this case nor in six cases of simple anæmia was any the body it was likely to influence those cells the proliferating power of which was greatest. Special proliferating power might exist under two conditions, natural and acquired. By acquired he meant loss of differentiation; in other words, loss of functional activity, so that such cells were no longer of any service in the economy and reverted practically to their embryonic state. When dealing with conditions where they could only theorise any explanation put forward could be judged in one of two ways. It could be disproved by facts or strengthened if supported by facts on which there was agreement. Applying the latter test to his theory he selected a few well-accepted facts—namely, the connexion of cancerous growths with long-continued irritation and with organs where senile changes were occurring—namely, physiological atrophy. He quoted the incidence of cancer in those whose natural body powers were declining through age. He discussed Cohnheim's conclusions, Ribbert's isolations, and Adami's groups. He cited also the influence of heredity, the conditions connected with cancer houses, the occurrence of carcinoma during pregnancy, and the mammary recurrences after long intervals. Dr. Beatson then went on to say that his views on the cancer process were as follows: that it could only develop in tissues that had special proliferating power, either natural, as in Cohnheim's "rests," or acquired in one of many possible ways. Further, the actual exciting cause of the cell proliferation was a secretion from all the tissues of the body and possessed of fructifying powers. A mutual relationship also existed between the character and amount of this secretion and the testes and ovaries. Another factor in connexion with it was the inherent vitality of the tissues themselves In that way alone could the disappearance of cancerous tissue under oöphorectomy be satisfactorily explained That was an instructive and important clinical fact which was altogether apart from the question of cure. Such a view of carcinoma was apparently a return to the old spermatic theory, but it differed from it in a very important point, because it did not imply a conversion of the normal tissue into another kind of tissue. Cancerous tissue was composed of ordinary body cells and all that the body secretion he had discussed did was to furnish a stimulus for proliferation when the condition of the cells allowed. The late Dr. C. G. Ritchie, whose work on ovarian physiology and pathology was full of interest, wrote the following suggestive remark: "Perhaps by the careful study of ovarian growths our knowledge of the nature of malignancy may some day be signally increased." Dr. Ritchie also said: "It is well to bear in mind what Dr. Bright enunciates so well that the ovaries in their natural structure seem to present a prototype of that involved system of cellular enlargement observed in malignant growths" Dr. Beatson concluded his remarks by discussing the general principles of treatment, in which he laid stress on oophorectomy and the administration of thyroid extract, in moderate doses, especially in connexion with inoperable mammary cancer with no visceral complications.

The meeting was then adjourned to March 18th.

---

## HARVEIAN SOCIETY OF LONDON.

*Exhibition of Cases.—Some Rare Cases of Sarcoma of the Thyroid Gland.*

A MEETING of this society was held on March 6th, Mr. W. Watson Cheyne, the President, being in the chair.

Dr. C. J. N. Longridge showed a girl, aged seven years, with an Irregular Temperature of three months' duration for which no obvious cause could be found Typhoid fever had been eliminated by repeated non-reaction to the Widal-Grunbaum test. No evidence of tubercle could be detected. It was not considered desirable to apply the tuberculin test on account of the irregularity of the temperature The only evidences of disease that could be detected were König's sign, which had lasted for six weeks, a transient erythematous rash, some pain and swelling of both wrists, and the temperature and wasting.—Dr. Penrose considered the case to be an obscure rheumatic condition.—Dr. E Cautley thought that this might be an early case of osteo-arthritis, and he believed that there was a little swelling about the wrist-joint. If so, that would support the view, and febrile attacks were a feature of some such cases. He had never seen a case of such long duration without definite joint change.—Dr. G. A. Sutherland agreed that there were cases of osteo-arthritis associated with high temperature. He thought that wasting was a striking feature in the case and agreed that there were wrist changes. Cardiac rheumatism was a possibility. He also thought that it might be a case of periodic paralysis and periodic vomiting, which cases were not generally well understood but seemed to be associated with a family complaint. He asked whether there was a history of a similar condition in other children of the family and what other illnesses the present patient had had.—Dr. Longridge, in reply, said that he had seen cases of osteo-arthritis in which the causal factor seemed to be a septic condition of the teeth, but the condition cleared up when the teeth were purified. The present child had bad teeth, but they were not septic The family history was good. She had two brothers older than herself and a younger sister, all robust. The only diseases which the present child had had were whooping-cough and measles.—In answer to the President he said that the red blood corpuscles were normal in number, but there was some leucocytosis, which had increased.

Dr Cautley showed a case of Disease of the Cauda Equina. The patient, aged 26 years, had a chancre eight years ago and presented a scar on his penis He was quite well until last October, when he had a sudden retention of urine. Four days later he could not hold his motions. He was treated by catheterisation and aperients, both as an out-patient and as an in-patient, at a hospital, but the disease was not diagnosed. Later the actual cautery was freely applied to the sacral region when he was in the infirmary. In December he began to have some loss of power in the left leg and numbness in the buttocks. At present he exhibited some loss of power in the extensors of the left leg. The cremasteric and patellar reflexes were very active, while the plantar reflex was lost. The sphincter ani had lost power and did not grasp the finger on examination. There was diminution of sensation to touch, pain, and temperature, with a feeling of numbness over a considerable area of the buttocks, the perineum, the penis, and the scrotum. Testicular sensation was impaired. He could not pass urine at first but now had partially regained control over the bladder. Stools were occasionally passed unconsciously. The probable diagnosis was syphilitic disease of the cauda equina, that part from which the second, third, and fourth sacral nerves arose He was treated with mercury and iodide of potassium.

Dr Cautley also showed a typical instance, clinically, of Primary Lateral Sclerosis in a man, aged 25 years. No possible exciting cause had been found except gonorrhœa about two years before the onset, which took place three years ago

Mr. P. L. Daniel read a paper on Some Rare Cases of Sarcoma of the Thyroid Gland and exhibited a large number of pathological and microscopical specimens from cases which had suffered from this disease.—The President said that sarcoma of the thyroid was apparently not very common. He was interested in the statement that out of six cases of malignant disease of the thyroid at Charing Cross Hospital four were sarcomata He had not generally examined such cases histologically, but had accepted the statement of the books as correct that sarcoma was much more rare than carcinoma. He had not yet encountered a case of malignant disease of the thyroid which he felt justified in operating upon; and those cases which did not seem to benefit under treatment were not kept in hospital, so that no opportunity of post-mortem examination was afforded The most interesting question was that of treatment, because malignant disease of the thyroid was one of the most terrible forms, on account of the great distress which it caused. In one case which was diagnosed as sarcoma of the thyroid a good deal of benefit resulted from the use of Coley's fluid. One case went on for more than a year; the patient was injected with Coley's fluid, and apparently there was a complete cessation of the growth But the patient had influenza and it lighted up again.—Mr Campbell Williams asked whether there was any pigmentation in the skin in these cases. He agreed that primary sarcoma or epithelioma of the thyroid was excessively rare.—Dr. Cautley asked whether in any of the cases the growths in the thyroid were secondary. Occasionally in cretins who were improving under thyroid treatment, if the treatment was stopped the thyroid began to enlarge, but it would go down again on the resumption of the treatment There was no doubt a connexion between the thyroid gland and the sexual functions.—Dr. Longridge asked whether there were any secondary growths in the of the ratepayers and necessitated hospital accommodation in excess of the real needs of the district. This view was accepted without any qualification by the committee of the Clinical Society of London[1] for the investigation of incubation periods and the duration of infectivity in 1892 on, Dr. Millard held, insufficient evidence, desquamation having been mentioned in no more than three of the 209 cases of scarlatinal infection recorded in their report edited by Dr. Simpson, and they admitted that infection might occur long after desquamation had ceased. With a view to elicit the opinions of the most competent authorities he had sent a number of questions to 25 medical superintendents of fever hospitals, some of whom were also medical officers of health; 16 of these expressed in decided and almost identical terms their disbelief in the old doctrine, while nine gave a more or less uncertain and qualified adherence thereto. Dr. Millard believed that not only was there no ositive evidence in favour of the old doctrine, but that there as much direct evidence against it. The streptococcus con- omeratus of Klein, which was very generally regarded as e specific microbe of scarlet fever, though present in the o-pharyngeal mucus and in the urine, had not been cted in the cast off cuticle, and the "striking distance" carlet fever was very short, though the dusty desquamation must be diffused far and wide through open windows; but there was no excessive incidence of scarlet fever in the vicinity of isolation hospitals, so that there was a strong contrast in this respect with the experience of small-pox hospitals. The supposed analogy between the scabbing of small-pox and the desquamation of scarlet fever was fallacious; pustulation, like suppuration, was evidence of the presence of bacteria, whereas erythema pointed to the action of a poison produced by bacteria in the organism rather than to that of the bacteria themselves, and erythemata produced by drugs were sometimes followed by similar desquamation. In his experience of several thousands of cases at Birmingham, and subsequently at Leicester, where the average period of detention did not exceed one month, the percentage of return cases following the discharge of patients still desquamating, though otherwise healthy, was certainly no greater than among others in whom it had ceased Recrudescence of infectivity did not accompany a secondary desquamation, but it often followed the occurrence of a naso-pharyngeal catarrh induced by an rdinary chill, when the microbes were doubtless still resent in the tonsils though until this accident in a dormant d inactive condition It might be advisable to avoid this shap by detaining patients for a day or two after their last infecting bath —Dr F F Caiger mentioned an instance of two return cases sent in 10 days after the discharge of a patient apparently perfectly well after eight and a half weeks in hospital.—Dr. C. B Ker said that at Edinburgh patients were sometimes sent out after six weeks, but he preferred to keep them for eight weeks The non-extension of the disease from hospitals as centres was, he thought, a very strong argument against the old view as to the infectivity of the desquamation.—Dr. F. M Turner acquiesced in the traditional notion from prudential motives Dr. Simpson's report appeared to be vitiated by his want of hospital experience and by his ignoring deferred infection —Dr. J W. Washbourn believed that there was no evidence whatever of the infectivity of the desquamation but that the period of infectivity of the patient might vary between three and eight weeks or more —Dr. E. W. Goodall, Mr Shirley Murphy, Dr. W. A. Bond, Dr. E. F. Willoughby, and the President also took part in the discussion

**Manchester Medical Society.**—A meeting of this society was held on March 5th, Dr Thomas Harris, the President, being in the chair —Dr J Dreschfeld made some observations on Hodgkin's Disease and on Splenic Anæmia He exhibited some patients to show the difficulty of clinically distinguishing between lymphadenoma and lymphosarcoma and drew special attention to the proportionate increase of lymphocytes in the former disease, though there might be no leucocytosis, as a distinguishing feature between the two As regards splenic anæmia, this term included a number of affections which had only two symptoms in common—namely, anæmia and enlarged spleen The splenic anæmia of children was often either a syphilitic or tuberculous affection, at other times the blood showed the character of pernicious anæmia The splenic anæmia of adults, in which besides the anæmia and the large spleen there was usually severe and repeated hæmorrhage (epistaxis, hæmatemesis, melæna), was often only the early stage of Banti's disease, marked enlargement of the liver at a later stage, though in several of the cases of anæmia which were evidently cases of Banti's disease which were fatal during the early stage, as shown by fibrosis of the spleen, the liver showed on examination distinct signs of cirrhosis. Dr. Dreschfeld exhibited a male patient, aged 26 years, as a good example of Banti's disease. There was marked anæmia, the spleen and liver were very much enlarged, there was as yet no ascites, the patient suffered from repeated epistaxis which was checked quickly by adrenalin, and lately he had developed purpuric spots on the legs. Analysis of the blood gave the following result: erythrocytes, 3,540,000; hæmoglobin, 66 per cent.; leucocytes, 4200, with polynuclear neutrophile cells, 58·8 per cent.; large lymphocytes, 7·6 per cent.; small lymphocytes, 32 per cent.; and eosinophile cells, 1 2 per cent. The blood in this case showed, as in many of the reported cases of Banti's disease, a marked increase of the lymphocytes, though the total number of leucocytes was diminished as compared with normal blood. The increase of the lymphocytes might be of some use in distinguishing Banti's disease from other forms of anæmia. Attention was also directed to the splenic anæmia due to the malarial parasite, to the splenic form of Hodgkin's disease, and to the remaining small group of cases of anæmia in which the spleen was enlarged and the blood showed the character seen in chlorosis.—Dr. Charles H. Melland agreed, as the result of a considerable number o blood examinations in cases of Hodgkin's disease, including those shown by Dr. Dreschfeld, that the characteristic blood condition was one in which there was absence of leucocytosis, or even slight leucopenia, with, however, a relative increase in lymphocytes. There had been at least three cases of the type of splenic anæmia described by Osler in the infirmary within recent years, with the typical symptoms of enlarged spleen, anæmia, and profuse recurrent gastric hæmorrhages. Whether these should now be called Banti's disease he was not prepared to say. There was no evidence of any affection of the liver in any of them.—Dr. A. Hill Griffith made some remarks on the diagnosis and surgical treatment of Front ethmoidal Mucocele and showed four patients who ha recovered from this condition and had had displacemen of the eyeball with diplopia and long-standing pain.—Mr. J. W. Smith showed a man, aged 35 years, on whom Excision of the Right Clavicle had been performed 13 months previously for a growth involving the inner two-thirds of the bone which had existed for five months. There was a history of precedent injury. At the operation adhesions between the posterior surface of the bone and the deeper structures presented the only difficulty. There were no signs of recurrence at the present time. As was usual in such cases the loss of the clavicle had made very little difference in the range of movement of the limb or in the symmetry of the shoulder, and the patient was now working as a labourer The growth was a chondro-sarcoma, showing areas of hyaline cartilage of a cellular type separated by strands of fibro-cartilage and small cell infiltration, other portions consisting entirely of small round sarcomatous cells

**Otological Society of the United Kingdom.**—A meeting of this society was held on March 3rd, Dr. Urban Pritchard, the President, being in the chair.—Mr. Hugh Jones (Liverpool) exhibited a Brain from a case of Cerebr Abscess in which a hernia cerebri developed three days afte the abscess was opened; a fortnight later a portion of the hernia was removed and the abscess was again explored, but no pus was found Death occurred three months after the operation —Mr Fagge suggested that the condition was not due to the removal of either too much or too little bone He thought that it was accepted as being due to a local and spreading infection, either another abscess or a diffuse infection of cerebral tissues. In two cases of failure he thought that the best line of treatment by which he might have saved his patient would have been to have removed all the area of the brain superficial to the abscess, leaving the bottom of the wound simply the bottom of the abscess cavity, thus making a funnel-shaped excision of the brain tissue.—Mr. Jones also showed a Microscopic Section of a Neoplasm from the External Auditory Meatus He considered the growth to be of the nature of a fibro-sarcoma He also exhibited some Foreign Bodies removed from the Middle Ear; one was a piece of coal removed from the ear of a collier, who material increase produced in the hæmocytes. Even if cacodylates were effective preparations of arsenic such an increase would not be anticipated, for he (the President) had more than 15 years ago convinced himself definitely that arsenical preparations were incapable of increasing either the red cells or the hæmoglobin in this disease. When cacodylate of iron was given in anæmia the condition was unmistakeably benefited, but this therapeutic effect was much the same as might at any time be obtained by administering any of the efficient iron preparations. It thus appeared that the arsenic in cacodylic acid and in its salts was almost inert when regarded either as a therapeutic or as a poisonous substance, but that when certain bases having therapeutic properties, such as iron, were united with cacodylic acid, these bases were capable of producing their special curative *effects. These results* were, the President considered, rendered intelligible when the chemical properties of cacodylic acid and its compounds were considered. He suggested that when a cacodylate was administered the arsenic remained locked up in it, in so far as its pharmacological energies were concerned. It thus remained inert pharmacologically, and, if so, necessarily also therapeutically, and it probably passed through the body without undergoing dissociation To determine the last point the urine of several of the patients who were receiving cacodylates was examined chemically with reference to the presence and form of the arsenic contained in it. Gautier had already shown that the arsenic in cacodylates could not be isolated by Marsh's process until the organic constituent had been destroyed by a very prolonged oxidation process devised by him. The result of the analyses of the urine in the President's patients was that arsenious acid dissolved in urine gave up the arsenic when treated with Marsh's process without any preliminary oxidation or destruction of the organic matter, whereas cacodylic acid failed to do so until the organic matter had been destroyed by a very prolonged and elaborate process of oxidation. The conclusions arrived at were the following. Clinical observations and chemical analyses agreed in showing that when a salt of cacodylic acid was administered to a patient it was absorbed and was eliminated, but with the arsenic which it contained so firmly combined with the other constituents that it did not become dissociated and was therefore incapable of forming any compound in the body which could produce the well-known pharmacological activities of the compounds of arsenic usually employed for therapeutic purposes. While, however, cacodylates were to be regarded as useless therapeutic agents in so far as they were compounds of arsenic, it might finally be observed that they were likewise inconvenient substances to administer to patients. In all the cases in which they were given by the mouth disorders of the alimentary canal—such as nausea, vomiting, and diarrhœa—were induced by them long before the maximal doses were attained, and in some cases these disagreeable effects required the administration to be suspended. Only when the administration was by subcutaneous injection did these disorders fail to be produced, but this was a method of administration which could rarely be continued over the long periods of time which were most usually required in the therapeutic use of arsenic preparations Further, even by subcutaneous injection, as by oral administration, the less important, though highly obnoxious, garlic-like odour of cacodylic oxide was always early produced, and it constituted an additional obstacle to the prolonged use of cacodylate These objections and inconveniences were, however, of secondary importance in view of the main result which had been arrived at—namely, that the compounds of cacodylic acid were apparently useless for producing the therapeutic effects of arsenic.

---

[1] THE LANCET, May 6th (pp 1066 and 1080) and 13th (p 1145), 1893.

Dr. D. **Noël Paton** contributed a paper on the Coördination of Medical Research in Edinburgh in which he noted the present waste of clinical material and the fragmentary character of the work done by individuals. He advocated the advantages of combination on definite lines of investigation with coördinated coöperation in supplying material and in prosecuting particular lines of work.

Mr. F. M. **Caird** showed (1) a girl after removal of an Intracranial Tumour; (2) a woman after partial removal of an Intracranial Tumour, and (3) a male patient, aged 68 years, after removal of a Portion of the Small Intestine for Tuberculous Intestine.

Dr. **Byrom Bramwell** showed (1) a case of Tabes with acutely developed ataxia in which great improvement had resulted from Frenkel's exercises; and (2) a case of Consolidation of the Left Lung, &c.

Mr **Miles** showed a Splint which could be adapted for use as single or double inclined plane.

Card specimens were exhibited by Mr. **Caird**, Mr. **Wallace**, Mr. **Miles**, and Dr. **Fleming**.

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF STATE MEDICINE.

### *Presidential Address.—Disposal of Old Surgical Dressings in Hospitals.*

A MEETING of this section was held on Feb. 14th, Dr. **Ninian Falkiner**, the President, being in the chair.

The **President** in his opening address gave a summary of the work of the Section of State Medicine for the 10 years during which he had acted as secretary. He then gave a short sketch of the birth and progress of the history of notification of diseases in England and presented a summary of the notification of certain infectious diseases in the cities of Dublin and Belfast, in the urban district of Rathmines, and the Pembroke urban district as published in the weekly reports of the Registrar-General for the year 1901.—Dr. J. **Craig** said that phthisis ought to be included in the list of infectious diseases to be notified to the public health authorities —Mr. J. P. **Doyle** said that syphilis ought to be included in the list of diseases to be notified for it was both contagious and infectious and modified all other diseases.—Mr. D. E **Flinn**, Dr. T. **Donnelly**, Dr. F. C **Martley**, and others also took part in the discussion.

Mr. H. **Gray Croly** read a paper on the Disposal of Surgical Dressings and other Refuse Matter in Hospitals. He considered that although surgeons took every care of the dressings that were put on their patients only a very small percentage asked what became of the used dressings. When many years ago he commenced practice, poultices, tow, and used dressings were too often pushed down the pan of the water-closet, and not infrequently they blocked the pipes, so that the closets were constantly being repaired. Some nurses stuffed them into unused corners until the morning cleaning came about, when they were carried off to the dust-bin to ferment and to rot until a scavenger carted them off. Every used dressing ought to be put into a covered bucket to be immediately destroyed in a quick-burning furnace. Lieutenant-Colonel J Backhouse, I.M.S., informed him that in the military hospitals of Calcutta, Madras, and Bombay, all used dressings were placed in a pail which had a concave perforated lid covered with fresh carbon, and were at once carried out beyond the hospital grounds and burnt in a quick furnace. In the Rotunda Hospital and some others in Dublin the furnace was used, but it ought to be used in all hospitals —Mr. R. F. **Tobin** said that years ago, when he was at Netley Hospital, a farmer contracted for the hospital refuse and utilised it as a top dressing for his land. On one occasion when hunting he was thrown off his horse in a field so manured and fell into some of their old dressings.—Dr. **Craig** said that a used poultice that a nurse had left lying in one of the wards in the Meath Hospital was eaten by a child. There was the further risk of flies carrying the infection from old dressings.—The **President**, Dr. H. **Potter**, and Mr. **Doyle** also discussed the paper.

**EPIDEMIOLOGICAL SOCIETY.**—A meeting of this society was held on Feb. 21st, Dr. Patrick Manson, the President, being in the chair.—Dr. C. Killick Millard, medical officer of health of Leicester, read a paper on the Supposed Infectivity of Desquamation in Scarlet Fever. He said that the belief that infection persisted so long as desquamation was present on any part of the body was firmly held by the general public, by nearly all medical practitioners, and by many medical officers of health. On no other evidence than the mere fact of peeling and in the absence of any actual infection parents had been prosecuted for allowing convalescent children to be at large and hospital authorities had been charged with spreading infection by the premature discharge of patients, such accusations being always supported by the family attendant and often by the medical officer of health, though mostly avoided by the detention of patients for needlessly long periods, a system which increased the burdens of the ratepayers and necessitated hospital accommodation in excess of the real needs of the district. This view was accepted without any qualification by the committee of the Clinical Society of London[1] for the investigation of incubation periods and the duration of infectivity in 1892 on, Dr. Millard held, insufficient evidence, desquamation having been mentioned in no more than three of the 209 cases of scarlatinal infection recorded in their report edited by Dr. Simpson, and they admitted that infection might occur long after desquamation had ceased. With a view to elicit the opinions of the most competent authorities he had sent a number of questions to 25 medical superintendents of fever hospitals, some of whom were also medical officers of health; 16 of these expressed in decided and almost identical terms their disbelief in the old doctrine, while nine gave a more or less uncertain and qualified adherence thereto. Dr. Millard believed that not only was there no positive evidence in favour of the old doctrine, but that there was much direct evidence against it. The streptococcus conglomeratus of Klein, which was very generally regarded as the specific microbe of scarlet fever, though present in the naso-pharyngeal mucus and in the urine, had not been detected in the cast-off cuticle, and the "striking distance" of scarlet fever was very short, though the dusty desquamation must be diffused far and wide through open windows; but there was no excessive incidence of scarlet fever in the vicinity of isolation hospitals, so that there was a strong contrast in this respect with the experience of small-pox hospitals. The supposed analogy between the scabbing of small-pox and the desquamation of scarlet fever was fallacious; pustulation, like suppuration, was evidence of the presence of bacteria, whereas erythema pointed to the action of a poison produced by bacteria in the organism rather than to that of the bacteria themselves, and erythemata produced by drugs were sometimes followed by similar desquamation. In his experience of several thousands of cases at Birmingham, and subsequently at Leicester, where the average period of detention did not exceed one month, the percentage of return cases following the discharge of patients still desquamating, though otherwise healthy, was certainly no greater than among others in whom it had ceased. Recrudescence of infectivity did not accompany a secondary desquamation, but it often followed the occurrence of a naso-pharyngeal catarrh induced by an ordinary chill, when the microbes were doubtless still present in the tonsils though until this accident in a dormant and inactive condition. It might be advisable to avoid this mishap by detaining patients for a day or two after their last disinfecting bath.—Dr. F. F. Caiger mentioned an instance of two return cases sent in 10 days after the discharge of a patient apparently perfectly well after eight and a half weeks in hospital.—Dr. C. B. Ker said that at Edinburgh patients were sometimes sent out after six weeks, but he preferred to keep them for eight weeks. The non-extension of the disease from hospitals as centres was, he thought, a very strong argument against the old view as to the infectivity of the desquamation.—Dr. F M. Turner acquiesced in the traditional notion from prudential motives. Dr. Simpson's report appeared to be vitiated by his want of hospital experience and by his ignoring deferred infection —Dr. J. W. Washbourn believed that there was no evidence whatever of the infectivity of the desquamation but that the period of infectivity of the patient might vary between three and eight weeks or more.—Dr E. W. Goodall, Mr. Shirley Murphy, Dr. W. A. Bond, Dr. E. F. Willoughby, and the President also took part in the discussion.

**MANCHESTER MEDICAL SOCIETY.**—A meeting of this society was held on March 5th, Dr. Thomas Harris, the President, being in the chair —Dr J. Dreschfeld made some observations on Hodgkin's Disease and on Splenic Anæmia. He exhibited some patients to show the difficulty of clinically distinguishing between lymphadenoma and lymphosarcoma and drew special attention to the proportionate increase of lymphocytes in the former disease, though there might be no leucocytosis, as a distinguishing feature between the two As regards splenic anæmia, this term included a number of affections which had only two symptoms in common—namely, anæmia and enlarged spleen. The splenic anæmia of children was often either a syphilitic or tuberculous affection; at other times the blood showed the character of pernicious anæmia The splenic anæmia of adults, in which besides the anæmia and the large spleen there was usually severe and repeated hæmorrhage (epistaxis, hæmatemesis, melæna), was often only the early stage of Banti's disease, marked enlargement of the liver appearing at a later stage, though in several of the cases of splenic anæmia which were evidently cases of Banti's disease which were fatal during the early stage, as shown by the marked fibrosis of the spleen, the liver showed on post-mortem examination distinct signs of cirrhosis. Dr. Dreschfeld exhibited a male patient, aged 26 years, as a good example of Banti's disease. There was marked anæmia, the spleen and liver were very much enlarged, there was as yet no ascites, the patient suffered from repeated epistaxis which was checked quickly by adrenalin, and lately he had developed purpuric spots on the legs. Analysis of the blood gave the following result: erythrocytes, 3,540,000; hæmoglobin, 66 per cent.; leucocytes, 4200, with polynuclear neutrophile cells, 58·8 per cent.; small lymphocytes, 32 per cent.; large lymphocytes, 7·6 per cent.; and eosinophile cells, 1·2 per cent. The blood in this case showed, as in many of the reported cases of Banti's disease, a marked increase of the lymphocytes, though the total number of leucocytes was diminished as compared with normal blood. The increase of the lymphocytes might be of some use in distinguishing Banti's disease from other forms of anæmia. Attention was also directed to the splenic anæmia due to the malarial parasite, to the splenic form of Hodgkin's disease, and to the remaining small group of cases of anæmia in which the spleen was enlarged and the blood showed the character seen in chlorosis.—Dr. Charles H. Melland agreed, as the result of a considerable number of blood examinations in cases of Hodgkin's disease, including those shown by Dr. Dreschfeld, that the characteristic blood condition was one in which there was absence of leucocytosis, or even slight leucopenia, with, however, a relative increase in lymphocytes. There had been at least three cases of the type of splenic anæmia described by Osler in the infirmary within recent years, with the typical symptoms of enlarged spleen, anæmia, and profuse recurrent gastric hæmorrhages. Whether these should now be called Banti's disease he was not prepared to say. There was no evidence of any affection of the liver in any of them.—Dr. A. Hill Griffith made some remarks on the diagnosis and surgical treatment of Fronto-ethmoidal Mucocele and showed four patients who had recovered from this condition and had had displacement of the eyeball with diplopia and long-standing pain.—Mr. J. W. Smith showed a man, aged 35 years, on whom Excision of the Right Clavicle had been performed 13 months previously for a growth involving the inner two-thirds of the bone which had existed for five months. There was a history of precedent injury. At the operation adhesions between the posterior surface of the bone and the deeper structures presented the only difficulty. There were no signs of recurrence at the present time. As was usual in such cases the loss of the clavicle had made very little difference in the range of movement of the limb or in the symmetry of the shoulder, and the patient was now working as a labourer. The growth was a chondro-sarcoma, showing areas of hyaline cartilage of a cellular type separated by strands of fibro-cartilage and small cell infiltration, other portions consisting entirely of small round sarcomatous cells.

**OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.**—A meeting of this society was held on March 3rd, Dr. Urban Pritchard, the President, being in the chair.—Mr. Hugh E Jones (Liverpool) exhibited a Brain from a case of Cerebral Abscess in which a hernia cerebri developed three days after the abscess was opened; a fortnight later a portion of the hernia was removed and the abscess was again explored, but no pus was found. Death occurred three months after the operation.—Mr. Fagge suggested that the condition was not due to the removal of either too much or too little bone. He thought that it was accepted as being due to a local and spreading infection, either another abscess or a diffuse infection of cerebral tissues. In two cases of failure he thought that the best line of treatment by which he might have saved his patient would have been to have removed all the area of the brain superficial to the abscess, leaving the bottom of the wound simply the bottom of the abscess cavity, thus making a funnel-shaped excision of the brain tissue —Mr. Jones also showed a Microscopic Section of a Neoplasm from the External Auditory Meatus He considered the growth to be of the nature of a fibro-sarcoma. He also exhibited some Foreign Bodies removed from the Middle Ear; one was a piece of coal removed from the ear of a collier, who claimed compensation for injuries to his left ear whilst at work. As he professed to be totally deaf it was clear that he was exaggerating his symptoms. A few days after this piece was removed another piece of coal, which was not there on the first occasion, was found in the other meatus. Another case was that in which a man was absent-mindedly playing with a collar-stud while reading, and allowed it to slip into the ear. When seen it was completely jammed in the meatus, and an incision had to be made behind the ear in order to remove it.—The President remarked upon the damage done at times by the introduction of instruments into the meatus to remove foreign bodies.—Dr. Cresswell Baber showed a case of Malformation of the Auricle associated with Asymmetry of the Eustachian Tubes.—Dr. Herbert Tilley showed a girl, aged 15 years, in whom a large Exostosis of the Left Auditory Meatus had been removed, revealing extensive destruction of the left tympanum and mastoid antrum, although no urgent symptoms had at any time been complained of. The complete post-aural operation and ultimate skin-grafting had been carried out. Pus was also present in the right maxillary antrum.—Mr. Arthur H. Cheatle showed a case of Tuberculosis of the Temporal Bone in an adult. The operation wound had quite healed, but there had subsequently developed a tuberculous elbow and a tuberculous abscess in the back.—Mr. P. R. W. de Santi exhibited a case of Jacksonian Epilepsy following operation for temporo-sphenoidal abscess of otitic origin, and also a case of Complete Bilateral Deafness with Left Facial Paralysis due to syphilitic intra-cranial mischief of the nature of basal meningitis.—Mr. Macleod Yearsley exhibited two specimens of Pedunculated Exostoses. One was removed from the meatus of a man, aged 45 years, by means of a cold wire snare, and the other from the meatus of a woman, aged 21 years, with a pair of dental stump forceps.

---

[1] THE LANCET, May 6th (pp. 1066 and 1080) and 13th (p. 1145), 1893.

Midland Medical Society.—A meeting of this society was held on Feb. 19th, Mr. Arthur Oakes, the President, being in the chair.—Dr. J. Martin Young showed a case of Angeioma of the Eyeball occurring in a child, aged 14 years. Two and a half years ago the right eye presented a leash of deep-coloured vessels on the nasal side of the cornea under the conjunctiva. The nasal half of the retina was detached and very black. The condition was diagnosed as one of melanotic sarcoma and excision was advised, but *the parents refused their consent. At the present time there* was externally a large vascular dark-blue mass on the nasal side of the eyeball. There was only light perception. The patient had suffered no pain at any time. The left eye was normal. The long history was held to negative the diagnosis of sarcoma and the condition was now thought to be nævus of the choroid. There was no history of tuberculosis in the family. The child was well in other respects.—Mr. Jameson Evans showed a case of Mooren's Ulcer of the Cornea. The patient, a woman, aged 49 years, came under his care in March, 1901, suffering from marginal ulceration of the cornea in each eye. As the ulcers resisted all the usual topical and constitutional remedies it became necessary to cauterise them. At the end of two months and after three cauterisations the right eye was completely cured except for a diffuse marginal opacity of the cornea. The left eye, though subjected to varying treatment, including periodical cauterisations, had steadily, though somewhat slowly, progressed until only a central piece of cornea of about the size of the pupil was left uninvolved.—Mr. J. Furneaux Jordan showed a specimen of Myoma of the Uterus removed by supra-vaginal hysterectomy. The patient, aged 40 years, had been married 14 years. She had had no children and no miscarriages. Menstruation had been regular and the quantity was not excessive. Six months ago she had noticed a lump in the abdomen which had rapidly increased in size, especially during the first two months after she had come under observation. The specimen was a multinodular myoma. It was removed by Kelly's method, the broad ligament tumours being enucleated, one from above downwards, and the other from below upwards. The cervix was divided at the level of the internal os. The operation was performed on Jan. 15th, 1902, and the recovery had been good except for the formation of a stitch abscess at about the eleventh day.—Dr. F. Edge read a paper on the Treatment of Abortion.

Æsculapian Society.—A meeting of this society was held on March 7th, Dr. Arthur T. Davies, the President, being in the chair.—Dr. E. W. Goodall opened a discussion on the Treatment of Typhoid Fever. During the fever stage, he said, feeding with milk three parts and water one part in quantities varying from two to three pints was ordinarily sufficient. If with this feeding the stools were lumpy and that was not remedied by diminishing the quantity of milk or increasing that of water the milk should be pancreatised before it was given. A week after the fever was over, and when the motions were not loose, solid food such as pounded fish and thin bread-and-butter might be allowed. As a stimulant he preferred spirit of camphor to alcohol. Of baths he favoured those of a temperature of from 75° to 80° F., and in winter 90°, allowing the immersion for 10 minutes up to 20 minutes. He thought that the benefit was not only that of a reduced body heat and he quoted the observation of Roque and Weill that the toxicity of the urine was increased during the treatment of Brand. The value of intestinal antiseptics was open to much doubt, though the fœtor of stools might be reduced by mercuric chloride or resorcin. Hæmorrhage should be treated by the avoidance of food by the mouth, the use of ice to the abdomen and full doses of opium, while the extremities were wrapped in cotton-wool. If perforation occurred, as soon as that was diagnosed, collapse not being present, laparotomy should be performed. In all cases needing catheterising urotropine should be given, as it should also if cystitis had developed.—The President said that mortality statistics at different periods were of but little help to treatment because of the variable intensity of the fever at different times.—A general discussion followed, to which Dr. Goodall replied.

*Anticipations of the Reaction of Mechanical and Scientific Progress upon Human Life and Thought.* By H. G. Wells. London: Chapman and Hall, Limited. 1902. Pp. 318. Price 7*s.* 6*d.*

*The Discovery of the Future.* A discourse delivered to the Royal Institution. By H. G. Wells, B.Sc. London: T. Fisher Unwin. 1902. Small 8vo, pp. 95. Price 2*s.*

Whither? This question, applied to the individual man and his destiny, has proved from the earliest historic time to be of absorbing interest, but as applied to the genus man, so far as we can judge, it has attracted, until quite recent times, but little notice and has awakened hardly any interest. Here and there a patriot has worked for the future of his country, now and again a philanthropist has taken a long look ahead at the wellbeing of posterity, but intellectual curiosity has seldom in the days before our own found scope for its exercise in the shadowy future, not of a free imagination, but of a fettered and strictly scientific forecast. Mr. Wells has made the experiment of a dip into futurity upon these terms and his success amply justifies his ambition. We speak in this connexion of his success without in any sense subscribing to his conclusions. It would be difficult either to endorse or to repudiate them in a word. They are so many and so diverse that unreserved acquiescence and uncompromising divergence of view are equally out of the question, nor, indeed, is the conclusion which is reached along any of the many lines which Mr. Wells follows in our opinion a matter of great consequence. We find ourselves differing from him and agreeing with him with equal composure. The mental exercise is the delightful thing and of this Mr. Wells gives us abundance. His argument is always ingenious, his information is copious, and his conclusions, right and wrong, are all suggestive and of the thought-compelling order. It is both a refreshing and an invigorating exercise to turn our history upside down and to argue in inverse order from the earlier to the later stage, from cause to consequence.

But while Mr. Wells gives us the impression of a very ingenious and powerful writer who has much to say that merits consideration he gives us an impression also of the inadequacy of the scientific method to the creative task of working down, as we have said, from cause to consequence.

It is like navigation upon what sailors call dead reckoning. In working up from ascertained facts to their causes we have the lode-star always in view, a fixed point by which we can at any moment try our course and ascertain our position. But working the other way we soon feel how low is the measure of certainty to which it is possible to attain when every deduction takes us further from, not nearer to, our ascertained facts. For this reason those parts of Mr. Wells's book appear to us to be of least interest in which he seeks to draw a moral and to prescribe an object to our collective action. For example, he is very urgent that we should take measures to extend in India and elsewhere the use of the English tongue. His intention is admirable, his discussion of the possibilities of what we may perhaps call "linguistic preponderance" is very illuminating, but he has not even considered the elementary question whether effort intentionally and manifestly directed to that end would not defeat its own object. There is something a little German, if we may say so without offence to him or to our continental neighbours, about the directness and simplicity of his method of influencing his fellow-men. It hardly seems to have occurred to him that where the voluntary action of free men is concerned the art of moulding their conduct consists largely in concealing the artifice by which it is done.

In "The Discovery of the Future" Mr. Wells continues to anticipate His theories are very plausible and it will be interesting for those who are here now when they enter upon the next life to see, if it be possible for those who have passed from this world to know what happens in it, the fulfilment or otherwise of Mr. Wells's speculation.

*A Manual of Practical Anatomy.* By the late Professor A. W. HUGHES, M.B., M.C. Edin., F.R.C.S. Eng. Edited and completed by ARTHUR KEITH, M.D. Edin., F.R.C.S. Eng. In Three Parts. Part I.: The Upper and Lower Extremities, pp. 274, with 38 Coloured Plates and 116 Figures in the Text, price 10*s.* 6*d.* Part II.: The Abdomen and Thorax, pp. 308, with Four Coloured Plates and 151 Figures in the Text, price 8*s.* 6*d.* London: J. and A. Churchill. Demy 8vo. 1901.

THE authors have wisely determined to issue this manual in three volumes of very convenient size. Two of these, dealing respectively with the Upper and Lower Extremities and with the Abdomen and Thorax, are now issued. The work, which bears the name of the late Professor A. W. Hughes, was incomplete at his death and has been ably completed by Dr. Arthur Keith.

The book is profusely illustrated. Some of the illustrations are old friends and are much the worse for wear, whilst others are quite new. The first part contains a large number of process reproductions of coloured drawings of the dissections in the Alfred Hughes collection at King's College. These are very disappointing, and being printed on thick paper they materially add to the weight and size of the volume. Perhaps this accounts for the absence of similar illustrations in Part II. The osteological plates showing muscular attachments are most useful and complete; they are erroneously attributed in the preface to Holden, whereas they are really woodcuts prepared under the supervision of Professor H. E. Clark, C.M.G., for Wilson's "Anatomist's Vade Mecum." Such illustrations as these are undoubtedly a great convenience to the student. Some diagrammatic outlines, showing the relations of the abdominal viscera and the vessels, nerves, and fasciæ of the pelvis, will prove particularly useful and are quite one of the best features of the book. We notice, however, that the position of the splenic vein in Fig. 166 does not correspond with that more correctly given in the text.

The various sections of the book are well arranged and e directions for dissections are lucidly given. The style is very terse, and in some places we are sure that the first year's student will not grasp the authors' meaning. Brevity can be cultivated at the expense of lucidity. But on the whole the brevity of description is a good point, as books of this description should only be guides to what the dissector must see for himself. Considerable care has evidently been taken in the description of the soft parts of the pelvis. The method of description of the pelvic fascia is clear but too concise; it departs in method somewhat from the description usually in vogue. An instructive diagram of the ovarian triangle has been inserted and particular care has been taken in giving the relations of the ureter.

When will pure anatomists begin to give a rational description of the actions of muscles? What the student and the clinician want to know is not what a muscle might conceivably do under inconceivable conditions but what it does in everyday life. There is no excuse for the continued ignorance manifested on this subject. The foundation for an accurate knowledge was laid by Duchenne in 1867 and a wealth of clinical material has accumulated since. This book perpetuates many of the old misstatements on this subject.

---

*The War Against Consumption.* By E DENNIS VINRACE, M.R.C.S. Eng., L.S.A.; Revised by JOHN H. VINRACE, M.B., M.R.C.P. Lond. London: Century Printing Co., Limited. 8vo. Pp. 178. 1901.

THIS is a popular handbook of the proceedings of the British Congress on Tuberculosis which was held in London in the latter part of July, 1901. The author was the representative of the Kensington Royal Borough Council. The book is a *résumé* of the opinions expressed by some of the authorities at the congress, with comments and explanations by the author, and it is intended to propagate among the general public accurate information concerning the present state of medical knowledge as to the origin and treatment of tuberculous disease. We wish the book a wide circulation, for it is certainly suitable for general reading, and can be understood by all. We are pleased to find that Dr. John Vinrace strongly discourages the idea that a suitable climate for every consumptive patient cannot be found in our own country. "I may assert," he writes, "without fear of contradiction that in a very large proportion of cases it is greatly to the patient's advantage to be treated here, rather than in some foreign land." We believe the information to be accurate and sound, and no one will fail to remark the unassuming modesty and quiet firmness of the author's views. We quite agree with all that is here advanced on the subject of climatic treatment, and we think that the chapter on the Open-air Sanatorium is excellent. The last chapter in the book is devoted to a consideration of the advantages that may be expected to accrue from the results of the deliberations of the congress. "There could be no greater mistake than to suppose that the discussions . .... are not likely to have any practical outcome, and that its work has been merely of academic importance." What the directions are which our efforts to suppress the disease should take are summed up under 12 headings, and the author really seems to think that the *laissez-faire* attitude so general in this country is being abandoned, and that the whole nation will take up arms in the war against tuberculosis. We only hope that it may be so, for the time for action is surely now.

---

*The Theory and Practice of Medicine.* By HENRY WALTER SYERS, M.A., M.D. Cantab., &c., Senior Physician to Outpatients to the Great Northern Central Hospital. In two volumes. Vol. I London: Rebman, Limited. 1901. Pp. 633. Price 15*s.*

THE author informs the reader in the preface that in this work he has attempted to describe the chief facts which underlie a knowledge of the principles and practice of compensation for injuries to his left ear whilst at work. As he professed to be totally deaf it was clear that he was exaggerating his symptoms. A few days after this piece was removed another piece of coal, which was not there on the first occasion, was found in the other meatus. Another case was that in which a man was absent-mindedly playing with a collar-stud while reading, and allowed it to slip into the ear. When seen it was completely jammed in the meatus, and an incision had to be made behind the ear in order to remove it.—The *President* remarked upon the *damage done at times* by the introduction of instruments into the meatus to remove foreign bodies.—Dr. Cresswell Baber showed a case of Malformation of the Auricle associated with Asymmetry of the Eustachian Tubes.—Dr. Herbert Tilley showed a girl, aged 15 years, in whom a large Exostosis of the Left Auditory Meatus had been removed, revealing extensive destruction of the left tympanum and mastoid antrum, although no urgent symptoms had at any time been complained of. The complete post-aural operation and ultimate skin-grafting had been carried out. Pus was also present in the right maxillary antrum.—Mr. Arthur H. Cheatle showed a case of Tuberculosis of the Temporal Bone in an adult. The operation wound had quite healed, but there had subsequently developed a tuberculous elbow and a tuberculous abscess in the back.—Mr. P. R. W. de Santi exhibited a case of Jacksonian Epilepsy following operation for temporo-sphenoidal abscess of otitic origin, and also a case of Complete Bilateral Deafness with Left Facial Paralysis due to syphilitic intra-cranial mischief of the nature of basal meningitis.—Mr. Macleod Yearsley exhibited two specimens of Pedunculated Exostoses. One was removed from the meatus of a man, aged 45 years, by means of a cold wire snare, and the other from the meatus of a woman, aged 21 years, with a pair of dental stump forceps.

**MIDLAND MEDICAL SOCIETY.**—A meeting of this society was held on Feb. 19th, Mr. Arthur Oakes, the President, being in the chair.—Dr. J. Martin Young showed a case of Angeioma of the Eyeball occurring in a child, aged 14 years. Two and a half years ago the right eye presented a leash of deep-coloured vessels on the nasal side of the cornea under the conjunctiva. The nasal half of the retina was detached and very black. The condition was diagnosed as one of melanotic sarcoma and excision was advised, but *the parents refused their consent. At the present time* there was externally a large vascular dark-blue mass on the nasal side of the eyeball. There was only light perception. The patient had suffered no pain at any time. The left eye was normal. The long history was held to negative the diagnosis of sarcoma and the condition was now thought to be nævus of the choroid. There was no history of tuberculosis in the family. The child was well in other respects —Mr. Jameson Evans showed a case of Mooren's Ulcer of the Cornea. The patient, a woman, aged 49 years, came under his care in March, 1901, suffering from marginal ulceration of the cornea in each eye. As the ulcers resisted all the usual topical and constitutional remedies it became necessary to cauterise them. At the end of two months and after three cauterisations the right eye was completely cured except for a diffuse marginal opacity of the cornea. The left eye, though subjected to varying treatment, including periodical cauterisations, had steadily, though somewhat slowly, progressed until only a central piece of cornea of about the size of the pupil was left uninvolved.—Mr. J. Furneaux Jordan showed a specimen of Myoma of the Uterus removed by supra-vaginal hysterectomy. The patient, aged 40 years, had been married 14 years. She had had no children and no miscarriages. Menstruation had been regular and the quantity was not excessive. Six months ago she had noticed a lump in the abdomen which had rapidly increased in size, especially during the first two months after she had come under observation. The specimen was a multinodular myoma. It was removed by Kelly's method, the broad ligament tumours being enucleated, one from above downwards, and the other from below upwards The cervix was divided at the level of the internal os. The operation was performed on Jan 15th, 1902, and the recovery had been good except for the formation of a stitch abscess at about the eleventh day.—Dr. P. Edge read a paper on the Treatment of Abortion.

**ÆSCULAPIAN SOCIETY.**—A meeting of this society was held on March 7th, Dr. Arthur T. Davies, the President, being in the chair.—Dr. E W. Goodall opened a discussion on the Treatment of Typhoid Fever. During the fever stage, he said, feeding with milk three parts and water one part in quantities varying from two to three pints was ordinarily sufficient. If with this feeding the stools were lumpy and that was not remedied by diminishing the quantity of milk or increasing that of water the milk should be pancreatised before it was given. A week after the fever was over, and when the motions were not loose, solid food such as pounded fish and thin bread-and-butter might be allowed. As a stimulant he preferred spirit of camphor to alcohol. Of baths he favoured those of a temperature of from 75° to 80° F., and in winter 90°, allowing the immersion for 10 minutes up to 20 minutes. The value of intestinal antiseptics was open to much doubt, though the fœtor of stools might be reduced by mercuric chloride or resorcin. Hæmorrhage should be treated by the avoidance of food by the mouth, the use of ice to the abdomen and full doses of opium, while the extremities were wrapped in cotton-wool. If perforation occurred, as soon as that was diagnosed, collapse not being present, laparotomy should be performed. In all cases needing catheterising urotropine should be given, as it should also if cystitis had developed.—The *President* said that mortality statistics at different periods were of but little help to treatment because of the variable intensity of the fever at different times.—A general discussion followed, to which Dr. Goodall replied.

## Reviews and Notices of Books.

*Anticipations of the Reaction of Mechanical and Scientific Progress upon Human Life and Thought.* By H. G. WELLS London: Chapman and Hall, Limited. 1902. Pp. 318. Price 7*s.* 6*d.*

*The Discovery of the Future.* A discourse delivered to the Royal Institution. By H. G. WELLS, B.Sc. London: T Fisher Unwin. 1902. Small 8vo, pp 95 Price 2*s.*

WHITHER? This question, applied to the individual man and his destiny, has proved from the earliest historic time to be of absorbing interest, but as applied to the genus man, so far as we can judge, it has attracted, until quite recent times, but little notice and has awakened hardly any interest. Here and there a patriot has worked for the future of his country, now and again a philanthropist has taken a long look ahead at the wellbeing of posterity, but intellectual curiosity has seldom in the days before our own found scope for its exercise in the shadowy future, not of a free imagination, but of a fettered and strictly scientific forecast Mr. Wells has made the experiment of a dip into futurity upon these terms and his success amply justifies his ambition We speak in this connexion of his success without in any sense subscribing to his conclusions It would be difficult either to endorse or to repudiate them in a word. They are so many and so diverse that unreserved acquiescence and uncompromising divergence of view are equally out of the question, nor, indeed, is the conclusion which is reached along any of the many lines which Mr. Wells follows in our opinion a matter of great consequence. We find ourselves differing from him and agreeing with him with equal composure. The mental exercise is the delightful thing and of this Mr Wells gives us abundance. His argument is always ingenious, his information is copious, and his conclusions, right and wrong, are all suggestive and of the thought-compelling order. It is both a refreshing and an invigorating exercise to turn our history upside down and to argue in inverse order from the earlier to the later stage, from cause to consequence

But while Mr. Wells gives us the impression of a very ingenious and powerful writer who has much to say that merits consideration he gives us an impression also of the inadequacy of the scientific method to the creative task of working down, as we have said, from cause to consequence blissful future before them. For the rest, women in love seem to have anything but a good time. Mr. Sutro's little sketches are pleasantly written and if there is nothing very new about his presentment of a theme as old as the world yet his book affords half an hour's interesting reading.

*The British Sanatoria Annual.* London: John Bale, Sons, and Danielsson, Limited. 1902. Pp. 158. Price 2*s.* 6*d.*—This little book, now in its third year of publication, gives an account of the various sanatoriums existing in the British Isles for the open-air treatment of tuberculosis. To judge by the many communications which are addressed to us upon this matter the existence and whereabouts of sanatoriums in Britain are but little known. The current issue of the book contains some abstracts of papers read at the Congress on Tuberculosis held in London in July, 1901. Altogether the compilation will be found very useful.

*The Fish River Bush, South Africa.* By W. T. BLACK, M.R.C.S., L.S.A. Edinburgh and London: Young J. Pentland. 1901. Pp. 55.—This volume is a reprint of articles contributed by the author to the *Edinburgh New Philosophical Journal* for July and October, 1853. They are founded on personal observations made by him when serving as assistant surgeon in the Caffre wars of 1847 and onwards. Everything about South Africa is of interest at the present time, and though no doubt vast changes have occurred in the country which Mr. Black describes, yet a detailed account of such a curious country is well worth reading. The bush as described is an almost impenetrable jungle consisting of thorny shrubs and small trees. Probably there is but little left of it now. Mr. Black gives some notes of the commoner animals which were found at the time of his observations within its fastnesses. As a record of, we should imagine, an almost vanished state of things we are glad to see these papers reprinted in an accessible form.

*Radiothérapie et Photothérapie.* By Dr. L. R. RÉGNIER. Paris: J. B. Baillière et Fils. 1902. Price 1 franc 50 centimes. Pp. 92.—This is a volume of the excellent little series of books known as "Actualités Médicales." Dr. Régnier commences by a survey of the theories of light and the various observers who have contributed to the solution of the problem. Though he mentions Huyghens and Fresnel we notice that he omits the name of Thomas Young who confirmed the wave theory of the former and discovered interference some 14 years before Fresnel wrote upon the subject. The author then considers the relations between energy existing as light, heat, and electricity. The more purely medical part of the book deals with the physiological effects of light-rays and of x rays. The various apparatus for applying these remedial agents are described and finally Dr. Régnier deals with the therapeutics of radiant energy in its different forms. The book is a simply and plainly written statement of the main facts of our knowledge of the subjects contained in it.

*Burdett's Hospitals and Charities, 1902.* London: The Scientific Press, Limited. Price 5*s.* Pp. 992 text; indices, viii.—This valuable compilation is quite up to its usual form and we need say little more. One new feature is a list of private sanatoriums for the treatment of tuberculosis. Another feature special to this year is the introductory chapter headed "Monarchy People and Hospitals." In this Sir Henry Burdett lays stress upon a point too often forgotten, that the London hospitals are not merely metropolitan institutions but Imperial institutions in that they receive patients from all districts of the Empire. Hence the Coronation gift should be contributed to by all classes and nationalities of the Empire.

---

VACCINATION GRANT.—Dr. P. L. Benson, Steeple Claydon, Bucks, has obtained the Local Government Board grant for successful vaccination for the eighth time in succession.

# Analytical Records

FROM

# THE LANCET LABORATORY.

### NEWSHOLME'S PORTABLE AMMONIUM CHLORIDE INHALER.

(G. T. W. NEWSHOLME, 27, HIGH-STREET, SHEFFIELD.)

THIS handy little apparatus is constructed on simple lines It is easily charged and easily kept clean. It consists simply of a wide glass tube closed at one end and fitted with a rubber cork at the other. A thistle-shaped funnel is fitted into the cork, the funnel being inverted and being suspended over a sponge at the bottom of the tube. A glass tube also fitted into the rubber cork serves as the inhaler tube. The funnel contains glass wool for absorbing the hydrochloric acid and the sponge is to be moistened with ammonia. On exhausting the inhaler tube air enters the thistle funnel and leaves the glass wool saturated with hydrochloric acid; it then impinges upon the ammonia sponge so that fumes of chloride of ammonium are formed which may be inhaled. Simplicity of construction is a decided advantage in an inhalation apparatus in order that it may be kept clean and in a satisfactory working state, and this is so with Newsholme's inhaler.

### VIROL.

(VIROL, LIMITED, 152 TO 166, OLD-STREET, LONDON, E.C.)

Virol is now manufactured on the large premises of the Bovril Co. We have submitted it to analysis on a previous occasion, but it has recently been improved in certain important respects. It is essentially a preparation of marrow fat and active malt extract, the fat not existing apparently as a separate entity until water is added, when an emulsion is formed exhibiting fat in an exceedingly fine state of division—a form in which it is readily absorbed and appropriated. Marrow fat, as is well known, contains natural glycero-phosphates which exercise a remarkably favourable effect upon the nutritive processes, especially in wasting diseases. Virol readily digests starchy compounds. According to our analysis it has the following composition: water, 29·37 per cent.; fat, 10·98 per cent.; proteids, 3·78 per cent.; malt extractives, 54·32 per cent.; and mineral matter, 1·64 per cent. The mineral matter proved to be rich in phosphates. The substitution of virol for cod-liver oil is grounded on a reasonable basis, considering its nourishing and tonic constituents and the particular way in which they are combined. Moreover, the flavour is attractive and the ingestion of virol is not followed by disagreeable eructations, as is the case with ordinary cod-liver oil.

### CASUMEN BREAD.

(PRIDEAUX'S PURE CASEIN AND LIFE FOOD CO., LIMITED, MOTCOMBE, DORSET.)

The addition of soluble milk casein to bread must necessarily raise its food value in direct relationship to the amount added. We have examined specimens of bread containing respectively 5 per cent and 10 per cent. of casumen. The bread was of excellent texture and of good flavour and possessed remarkable keeping qualities. The casumen loaves kept moist and plastic for over a week and after that time were still "new" as regards flavour. The casumen is dissolved out easily by hot water. In experiments directed to the determination of the digestibility of the bread, using acid pepsin, the percentage amount of total proteids digested was the same in regard to ordinary bread and casumen bread, but the actual gain of proteid is as much as 65 per cent. when bread containing 10 per cent. of casumen is substituted. This, of course, is an indisputable dietetic gain, the flesh-forming constituents medicine. We have carefully perused this volume, but we cannot say that we have been favourably impressed. We perfectly agree with Dr. Syers that in a book dealing with the principles of the subject all matters which are superfluous should be omitted, and that amongst such matters are long disquisitions on morbid anatomy which it is impossible for the student to understand unless he has large post-mortem experience. Dr. Syers has, however, gone too far in this curtailing process, with the result that in our opinion the book will be of little use to the student in preparing for examination, and the practitioner will find little to guide him in the conduct of an obscure case, especially if the diagnosis is in doubt. The subject of differential diagnosis is but very briefly touched upon. Take, for instance, the chapters on small-pox and chicken-pox, some of the most important diagnostic differences are omitted, whilst in a doubtful or modified case of small-pox we are afraid that Dr. Syers's observations would not be of much value to the perplexed practitioner.

The author acknowledges that but brief attention has been devoted to treatment by drugs, but he excuses the omission by stating that the proper details of therapeutics should be sought in books devoted to that subject. We do not agree altogether with this statement. The busy practitioner does not wish to search through a volume on therapeutics in which several methods of treatment are suggested for any one disease, but he requires a volume on medicine stating the opinion of a physician of experience who has already tried the various plans suggested and has come to a conclusion as to which is most likely to give satisfactory results. Further, Dr. Syers entitles his book "the Theory and *Practice* of Medicine," which surely includes a knowledge of drugs.

We regret that we cannot congratulate Dr. Syers on the results of his labours The book is lacking in the details which are necessary in a text-book on general medicine.

---

## LIBRARY TABLE.

*The Literary Year-Book and Workman's Directory, 1902.* Edited by HERBERT MORRAH. London: George Allen —The sixth issue of the "Literary Year-Book" shows a considerable advance upon previous issues. The directory of authors, which forms the bulk of the book, is a valuable compilation It is a long list containing the names of the best known writers and of many others accompanied by a certain amount of authentic information as to their work. The directory is, of course, not complete, and it never will be complete, for the difficulty of defining what constitutes an author is considerable and there are sure to be regrettable omissions and inclusions. Some writers, also, are much more communicative than others as to their personal affairs, so that the assistance received by the editor has been, and will be in all future editions, very capricious. We notice that a few medical writers find a place in the directory, but here no principle seems to have been followed, for we looked in vain for the names of Sir Lauder Brunton, Sir Frederick Treves, Professor Osler, Dr. F. Taylor, Dr. Playfair, Dr. Galabin, Mr. Henry Morris, Mr. William Rose, and Mr. D'Arcy Power—to mention a few whose literary work is familiar to our readers The editor's summary of the year's work of 1901, which is written in the confident manner of an able man, contains much that is true and much that is debateable, but medical authors are not largely concerned in the conditions of general authorship. If they require advice as to the best methods of publishing, as to the meaning of their agreements, or as to the fairness of any royalty that is offered to them, they will do well to consult the Society of Authors.

*The Climate and Mineral Waters of Caledon, South Africa.* By G. W. B. DANIELL, M.R.C.S. Eng., L.R.C.P. Lond., Medical Superintendent, Caledon Mineral Baths Sanatorium. London: John Bale, Sons, and Danielsson. 1902. 8vo, pp. 54. Illustrated.—This is a reprint, with additional matter, of a paper published in our contemporary the *Journal of Balneology and Climatology* in October, 1901. The book is well bound and clearly printed and contains six photographic views of Caledon and the sanatorium. Caledon is a village situated on the southern aspect of a range of mountains within easy distance of Table Mountain and Cape Town There is at present no railway from Cape Town, and this is a great disadvantage, as it renders a five hours' drive in a Cape cart necessary, and Cape carts are not the most comfortable of vehicles. Still, it is possible to hire a better carriage for the drive, and it must be conceded that the roads are good The village itself is at an elevation of about 850 feet above the sea-level. The climate of this neighbourhood is equable and dry; the mean annual temperature is 62 3° F. and the mean annual rainfall is 20 inches There are no "dust-storms" in this part of the colony and frost is almost unknown even in winter nights. It is claimed for the climate of Caledon and its neighbourhood that it is bracing and never too hot, as is Cape Town, which lies, of course, on the sea-level. The springs of Caledon, seven in number, are thermal and chalybeate, rich in ferrous carbonate, and unusually free from organic impurities. Professor P. D. Hahn and Professor J. Attfield have made analyses which will be found recorded in detail in the book The total yield of water every day is about 180,000 gallons, and at the mouths of the springs the temperature of it is about 120° F. We are glad to be able to record that we know people who have been greatly benefited at Caledon Baths, and from a knowledge of the local climate we are quite in agreement with Mr. Daniell that patients with rheumatism and Bright's disease may expect to do well there. The waters are not unduly astringent, though chalybeate, and are non-irritating to the digestive tract. "It has been remarked," writes the author, "that there is quite a 'boom' in sanatoriums at the Cape. Show me a country more in need of such establishments, and one of more natural advantages, and I will admit that the 'boom' should not exist." This is all very well, but a sufferer need not go so far as South Africa to be relieved of rheumatism or Bright's disease, of anæmia, or the malarial cachexia. There is too much going abroad to seek after health and we too often ignore the natural resources of our own little island. There are thermal chalybeate springs in Great Britain every whit as good as those anywhere in Cape Colony, if chemical analyses and records of improved health are anything to go by.

*Woman's Best Work and Latent Capabilities* By FREDERICK JAMES GANT, F.R.C.S *Eng.* London: Elliot Stock. 1902. Pp. 107. Price 2*s*. 6*d*.—Those familiar with Mr. Gant's former works, "Perfect Womanhood" and "The Latest Fruit is the Ripest," will find in the little book now before us some further details as to Sister Eva. We somehow have not much faith in spiritual unions between two ordinary carnal mortals such as were Algernon and Eva. However, Algernon did not survive very long, which was, perhaps, the best way out of the difficulty. Eva and Algernon are considered in Chapter I. The rest of the book is taken up by remarks upon woman's work in the spheres of hospital nursing, rescue work, and the like, and Mr. Gant writes with all his well-known heart-whole enthusiasm as to women medical practitioners.

*Women in Love.* By ALFRED SUTRO. London: George Allen. Pp. 284 1902. Price 6*s*—The sub-title of Mr. Sutro's book is "Eight Studies in Sentiment" and the tendency of six studies out of the eight is to show that happiness is not acquired by going outside the conventional bounds set for the regulation of sexual relations. From our narrow point of view as medical journalists we are glad that of the two couples who seem likely to be happy Dr. Rogers and Vivien Meadows have to all appearances a

THE LANCET.

*LONDON: SATURDAY, MARCH 15, 1902.*

# The Leicester Guardians and Vaccination.

THE appeal in the case of MOORE *v.* KEYTE disposed of by the Divisional Court last week was of importance because if the contention of the Leicester Guardians, whose conduct was in issue, had been held to be correct, the Vaccination Acts would have been liable to be abrogated in any locality at the pleasure of the guardians of the poor for that locality. This result, it will be remembered, the Leicester Guardians endeavoured to bring about in 1899 by appointing as vaccination officer a person holding their own views as to the undesirableness of vaccination. The Local Government Board refused to sanction the appointment and the intervention of the court compelled the appointment of a person who would carry out the duties of his position, and eventually such a person was duly appointed and approved by the Board. The policy since adopted by the Leicester Guardians was exhibited in a resolution passed by them condemning the action of their new vaccination officer in prosecuting offenders under the Vaccination Acts without the guardians' instructions, and instructing him in future to report defaulters to the Board so as to afford them an opportunity to offer a reasonable excuse. Section 29 of the Vaccination Act of 1867 provides that "every parent or person having the custody of a child who shall neglect to cause it to be vaccinated . .... and shall not render a reasonable excuse for his neglect shall be guilty of an offence, .... .." but the view that the excuse might be offered to guardians and not to the magistrates hearing summonses for neglect to vaccinate was, we believe, first suggested by the ingenious guardians of Leicester whose resolution referred to went on to say that the authority to prosecute, if given by them, would be given under their common seal. On two occasions, in compliance with the terms of this resolution, the Leicester vaccination officer presented lists to the guardians of persons whom he deemed it desirable to prosecute, and on each occasion resolutions promptly followed instructing him to take no further steps with regard to the institution of proceedings until instructed by the guardians. No instructions to prosecute were ever given, but the vaccination officer took proceedings nevertheless and secured the conviction of an offender, the appellant in the present case. The ground of appeal was not only the absence of authority from the guardians to prosecute, but also the absence of proof by the vaccination officer that the public vaccinator had given the prescribed notice of his intention to visit the house of the person summoned, and that he had, in fact, so visited and offered to vaccinate the child.

Mr. RAWLINSON, K.C., argued the appeal from the point of view of the Leicester Guardians and their supporters. The Attorney-General claimed to be heard on behalf of the Local Government Board on the ground of the important public interests involved, affecting the duties of that department. The court heard Sir ROBERT FINLAY on these grounds, expressly intimating that it did not do so on account of any serious doubts felt by it on the subject of the appeal, and counsel for the respondent was not called upon to argue. There were two points, as we have indicated, for decision, the first and most important being, as expressed in the case stated by the magistrates, whether the vaccination officer by virtue of his appointment as such, without directions, general or special, from the guardians, at any time and notwithstanding the guardians' direction not to prosecute in certain specified cases, could institute proceedings under the Vaccination Acts of 1867 to 1898 as vaccination officer of the guardians. On this point the judgment delivered by Lord ALVERSTONE was clear and decisive. He held that it was for the magistrates when the case came before them, and not for the guardians, to decide what was a reasonable excuse for the non-vaccination of a child, and he had no doubt whatever that it was the duty of the vaccination officer to take proceedings independently of the wishes or instructions of the guardians. To this conclusion his lordship would have come under the wording of the Vaccination Act of 1898, but he added that the wording of the order of the Local Government Board published since the passing of the Act made the matter more abundantly clear. The case of BRAMBLE *v.* LOW decided a similar point under Section 31 of the Vaccination Act of 1869 and the orders of 1874 in similar fashion. The true view was that the vaccination officer was bound to obey the order of the Local Government Board and that any order of the guardians contrary to that order would not be a legal order or one that the vaccination officer would be bound to obey. On the second question—namely, whether it was a condition precedent to a prosecution by a vaccination officer under Section 29 of the Vaccination Act, 1867, that due proof must be given of the public vaccinator having previously given notice of a visit and having visited the house—the Lord Chief Justice held that the absence of the visit and notice might well be urged before the magistrates on the hearing of a summons and might be treated by the magistrates as a reasonable excuse for non-compliance with the Act, but that this was a long way from the proposition that the onus of proving the performance of such matters lay upon the prosecution.

With regard to both questions involved in the case of MOORE *v.* KEYTE there is, therefore, direct judicial authority unless and until some new Act of Parliament intervenes. We say this because we notice that a private Member, with a promptitude worthy of a better cause, has already introduced a Bill in the House of Commons which provides that no prosecution under the Vaccination Acts shall be commenced without the authority of the guardians. Fortunately, in some cases at all events, the efforts of the private Member to legislate are not frequently or rapidly crowned with success. That which has not been decided, but will, we apprehend, some day occupy the courts, is whether guardians are liable to pay the costs of unsuccessful prosecutions instituted without their sanction and contrary to their instructions by their vaccination officer. If it is decided that the guardians are so liable the whole matter will be concluded.

in casumen bread being nearly double those contained in ordinary bread.

### CASUMEN BISCUITS.

(W. DUNMORE AND SON, MIDLAND BISCUIT WORKS, SOUTH WIGSTON, NEAR LEICESTER.)

It is stated that these biscuits contain 10 per cent. of soluble milk casein (casumen). This statement is completely confirmed by our results of analysis which showed the presence of 19·33 per cent. of proteid. Since biscuits made with ordinary flour contain about 10 per cent. of proteid, the addition of absolute casein to the bread amounts to 9·33 per cent. Warm water easily dissolves the added casein which readily yields to the digestive action of pepsin. The biscuits are somewhat dry to the taste but are crisp and of good texture. They have, however, a decided tendency to crumble. According to analysis they are 100 per cent. more nourishing than the ordinary milk biscuit, while they are better entitled to the name since they contain pure milk proteid in rich proportion.

### ROWNTREE'S ELECT COCOA AND SWISS MILK CHOCOLATE

(ROWNTREE AND CO, LIMITED, COCOA WORKS, YORK.)

We have examined this cocoa and find it to be of excellent quality with more than half of the indigestible cocoa fat removed and possessing a maximum degree of so-called "solubility." It leaves little or no sediment in the cup as the result of a special method of manufacture. On account of this method the mineral matter was rather excessive, showing a degree of alkalinity equivalent to 2·77 per cent. potash ($K_2O$). The cocoa possesses a fine aromatic flavour. The moisture amounted to 5·3 per cent and the fat to 29·25 per cent. We have received also specimens of Swiss milk chocolate from this firm. The combined flavour of cream and cocoa is agreeable. The chocolate is very nourishing and is a useful and portable article of food.

### TABLOID ASPIRIN.

(MESSRS. BURROUGHS, WELLCOME, AND CO, SNOW HILL-BUILDINGS, LONDON, E C)

Aspirin is an acetyl derivative of salicylic acid which is said to offer advantages over the acid or its salts in the treatment of rheumatic conditions. The tabloid contains five grains of aspirin, a white crystalline compound.

### PURE FRUIT SYRUPS.

(JOH. STORKHUYZEN, HOLLAND, LONDON AGENCY, S. DUSSIISMA, CENTRAL CHAMBERS, 17, CHEAPSIDE, E C.)

As might be expected, these syrups consist chiefly of sugar varying in amount from 74 per cent. to 85 per cent. According to some tests which we made we believe them to be genuine fruit syrups without foreign colouring matter. Moreover, they possess the true flavour and aroma of the respective fruits. We examined the cherry, strawberry, and raspberry syrups. In spite of the preponderance of sugar the manufacturers evidently find the addition of a small quantity of salicylic acid for preserving purposes necessary.

### TOILET REQUISITES.

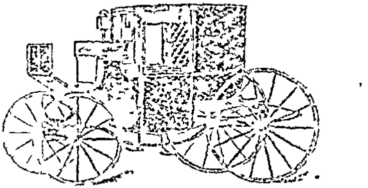
(THE TOILET NOVELTIES CO, BRISTOL)

These "requisites" are important to personal hygiene. The aseptic handkerchiefs in the large form are composed of Japanese paper, the material being known as silky fibre, a by no means inappropriate term They are beautifully soft and possess the important quality of being highly absorbent. They are strongly bibulous—a property which renders them well adapted for the reception of sputa or mucus, as in infectious colds or tuberculosis. The handkerchiefs are bordered with a pattern resembling the embroidery of an ordinary pocket-handkerchief. Other toilet requisites consist of sanitary paper in the form of a household toilet-book, or of a toilet pocket-book, containing readily detachable papers made, it is said, from chemically pure paper. Several sizes of pocket-book are made supplied with a stiff cover, fastening much in the same way as an ordinary leather pocket-book. Each leaf may readily be withdrawn without disturbing the remainder. These requisites will be appreciated by travellers and especially by those who travel abroad. They are inexpensive and add little to impedimenta. The use of any common paper for toilet purposes is an objectionable and insanitary practice

# New Inventions.

### THE "CORTLAND BROUGHAMETTE."

THE day of the general adoption of the motor-car for professional requirements being not yet, we still are dependent mainly upon horse traction to supply our needs The Cortland Wagon Company, of Henrietta-street, Covent Garden, W.C, are not, apparently, impressed with the idea that we shall quickly see a change in this latter method, as they have invited us to inspect their "Cortland Broughamette," which they have specially designed for the medical profession, and in the construction of which they have endeavoured to combine all the best English and American features The broughamette is hung on highly-tempered steel springs of a special character and is tyred in solid rubber. Every effort has been made to prevent vibration and "chattering," with excellent results, and both hum and rattle are banished. The body is very roomy and comfortable, its upholstering is in good taste combined with utility, and the fittings are in keeping with those obtaining in the best vehicles. The new broughamette is extremely light, weighing but five and a half hundredweight, this lightness being attained by the use of special materials in its construction which insure the strength as well as lightness of the vehicle.



The "Cortland Broughamette."

# ASYLUM REPORTS.

*London County Asylum, Cane-hill (Report for the year ending March 31st, 1901).*—The average number of patients resident during the year was 2215, including 947 males and 1268 females The admissions during the year amounted to 440—viz, 264 males and 176 females. Of these 370 were first admissions Mr. James M. Moody, the medical superintendent, states in his report that "a large proportion of the admissions were unsatisfactory in regard to the prospect of recovery—viz, 50 per cent. of the females and 67 per cent of the males" The number of patients discharged as recovered during the year amounted to 150—viz, 80 males and 70 females, or 6·8 per cent. of the average number resident. The deaths during the year amounted to 190—viz, 130 males and 60 females, or 8·5 per cent. as calculated on the same basis. 15 males and 88 females died from pulmonary tuberculosis. "Endeavours are now being made," adds Mr. Moody, "to isolate phthisical cases, and the open-air treatment will be carried out as far as possible." The general health of the institution has been satisfactory during the year, no epidemic or zymotic disease having prevailed. 11 patients escaped, and of these nine were re taken and brought back. Two female patients admitted while pregnant were safely delivered, one prematurely and the other at full term. New works have been undertaken in connexion with softening of the water-supply and the drainage of the isolation hospital, attendants' cottages, and farm. The Commissioners in Lunacy state in their report that the general condition of the asylum was very satisfactory, the wards and day-rooms were bright, cheerful, and comfortable, the dress of the patients was neat and tidy, and that the medical case-books were well kept and illustrated with excellent photographs of patients. The expenditure on repairs and alterations during the year amounted to £5343.

molecular granulations possessing great refractive power placed between the cells, and in this opinion he is supported by Professor Virchow, Professor Dressler, and Professor Chiari. Dr. Dock, whilst giving his adherence to the fatty theory, considers that it is simply an exaggeration of the greenish tint so common in the neoplasms of leukæmia. Dr. Dunlop opposes this theory on good grounds—namely, that the colour quickly disappears on exposure to air and on immersion in fluids that have no solvent action on fats. He believes that the colour is more probably due to some chemical product, hitherto undiscovered, allied to lipochrome, which on exposure to light becomes oxidised and in the process of oxidation loses its colour. Dr. Bramwell stated that in the case recorded by him the change in colour which the cutaneous lesions went through during life was suggestive of a blood change, and the marked increase of the green colour which was noticed at the post-mortem examination in the skin lesions in the upper part of the body seemed to be suggestive, in part at least, of a post-mortem change (? decomposition). It is obvious, therefore, that observers are far from being unanimous in determining the nature of the green colour seen in chloroma, and there is an interesting field open for further investigations. It is possible, as Dr. Bramwell suggests, that the colour may be due to different causes in different cases, but we think that this theory tends only to complicate matters and we deem it more probable that a similar cause will be found to be acting in all cases. Dr. Bramwell introduced another point in regard to the colour. He was disposed to think that the green discolourations, though they had hitherto been considered to be essential and characteristic features of the disease, might in some undoubted cases of chloroma be absent. We are not aware that this question has been raised by other observers; if Dr. Bramwell is correct in his supposition the term "chloroma" will have to be altered.

The histological nature of the growths was discussed at length by both speakers. Dr. Dunlop was of opinion that "lympho-sarcoma" was probably the best definition of their structure, resembling on the one hand lymphoma in their histological characteristics, and on the other sarcoma in the fact that they arose from the periosteum and that they spread by metastasis. Dr. Bramwell also brought forward arguments in favour of the lympho-sarcomatous nature of the growths He pointed out, however, that the condition of the blood was highly suggestive of lymphatic leukæmia, and in Dr. Dunlop's case the changes in the blood might well have led to a diagnosis of acute lymphatic leukæmia had it not been for the appearance of the green growths. The question then arises whether chloroma is a definite and distinct disease or merely a variety of lymphatic leukæmia Probably more than one disease are included under this term; varieties certainly have been shown to occur, and as the knowledge of pathological conditions of the blood becomes greater a more definite differentiation will be possible. All that has hitherto been demonstrated is that cases of lymphatic leukæmia present considerable differences in their clinical history and course and in the relative intensity of the lesions found after death in the bone-marrow, the spleen, and the lymphatic glands respectively. It is evident that there is a large field for investigation in these varying conditions of the blood. The knowledge of the corpuscles of the blood in health and more particularly in disease has been greatly added to during recent years. Improved methods of staining have indicated pathological changes hitherto unknown. Valuable aids to diagnosis and prognosis have been demonstrated, and as the methods of examination are elaborated more clear and definite views of the pathology of the blood will be obtained.

◆

# The Choice of a Disinfectant.

The question as to what is the most convenient, and at the same time most effective, disinfectant for practical purposes is one, of course, of the utmost importance to the medical officer of health, to the general practitioner, and to the public. We have often wished that some definite, and preferably official, pronouncement, based upon trustworthy practical tests, could be made once for all, if only to show that the choice of an efficient disinfectant lies between only a few substances. The list of disinfectants which are urged upon the notice of the practitioner by those interested in their sale is a never-ending one and only bewilders him. Chemists in their untiring search for new compounds frequently succeed in discovering one which is a more powerful germicide than many of its antecedents, while it is a less powerfully poisonous substance, but some of the new discoveries are certainly not in the nature of improvements. We think, therefore, that in the practical experiments on disinfection recently undertaken for the London County Council by Dr. E. Klein, Dr. A. C. Houston, and Dr. M. H. Gordon these gentlemen were wise in limiting their investigations to those disinfectants most commonly in use. The results of the trials have just been published in an official paper issued by the London County Council. The disinfectants tested were (1) carbolic acid; (2) permanganate of soda; (3) bleaching powder; and (4) corrosive sublimate, all of which were used dissolved in water in suitable proportion. In addition, and as examples of gaseous disinfectants, formaldehyde and sulphur dioxide were tried, Dr. G. Newman, the medical officer of health of Finsbury, being responsible here for a share of the experimental work.

The microbes experimented with were (*a*) the spores of bacillus anthracis; (*b*) the staphylococcus pyogenes aureus; (*c*) the bacillus of typhoid fever; (*d*) the bacillus of diphtheria; (*e*) the bacillus pyocyaneus; (*f*) the vibrio of cholera; and (*g*) the bacillus of human tuberculosis. The above list represents a selection of microbes which are met with and which *need to be destroyed* practically every day. Moreover, the species chosen for investigation have this great advantage;—their survival or destruction could be easily ascertained, some developing colours, others cultural characters, and the rest exerting a specific action when injected. We need not enter into the details of the experiments; suffice it to state that as far as possible practical conditions were imitated. The materials infected were wood, cloth, linen, and paper. With regard to the results, Mr. Shirley F. Murphy, the medical officer of the Council, states in his summarising preface to that body, that it was found that both formaldehyde and sulphur dioxide failed in the case of wood and cloth

# A Plea for the Study of Minor Ailments.

THERE are several striking features by which the medical and surgical practice of hospitals is contrasted with what is called private practice. At first sight it might seem strange that where the aim in each instance is the same the conduct should often be so different. To the hospital physician and surgeon, as to the general practitioner, the first object is the improvement of the patient's malady. How comes it, then, that the means by which improvement is secured are often so far removed in the institution from those which prevail outside it? A main cause for this difference is at once apparent when we consider the patient's malady. No revelation is more perplexing to the young practitioner fresh from hospital work than this—the majority of his patients seek his aid on account of ailments which were not seen, or were thought of little account, in hospital work. Instead of finding that for every case with which he is confronted he can at once remember a parallel supplying him with confidence in his treatment of his patients, he realises to his surprise that now for the first time he is called upon to deal with some common ailment of which he has often heard, from which, indeed, he may have suffered, but to which he has never had his attention directed during his days of pupilage. His ingenuity in devising suitable treatment becomes at once subjected to a severe test. Qualities are asked of him for which he has hitherto had little need, and thus it happens often that coolness and tact, if based on sufficient knowledge, may lead the practical young man to early success that may be denied to the "best man of his year" who, with a large amount of definite knowledge, lacks the accessory qualities which permit this to be brought into play in private practice

Recent correspondence in our columns on the treatment of the common cold and the removal of the unsightly wart would in itself suffice to show how great an interest for practitioners may centre round a subject which the text-book or the lecturer on medicine passes by with a word or two. Minor ailments are common ailments. Common ailments provide the bulk of practice; while it is rare cases that loom large in the student's eye, and it is mainly from the exceptional instances that his teachers provide their lectures and demonstrations. Yet these common ailments should provide as much food for reflection as the most elaborate medical problem. The common cold is not more easily explained than the etiology of pernicious anæmia, and Friedreich's hereditary ataxia is almost as amenable to treatment as a simple headache in certain persons. Yet hundreds of pathologists and bacteriologists probably busy themselves about the more high-sounding diseases, for every one who attempts to unravel the equally obscure problems of a so-called simple complaint. This is a practical error, for surely that disease which affects the largest number ought to be grappled with first. The grave diseases have, of course, grave results—a fact which gives them their appearance of overwhelming urgency—but the results of the lesser maladies when they become recurrent in the same individual, as they so often do become, are not to be despised. From the point of view purely of the medical man minor ailments have a peculiar interest denied to the rarer or more serious classes of disease. The latter may be met with in hospital and out of it, but are best studied by those in attendance in institutions where in a few weeks as many instances may be seen as a general practitioner would meet in his lifetime. With the common and slight ailments just the reverse is the case These are, so to speak, the general practitioner's field. It behoves him, then, who has charge of this estate to reap from it a harvest of information whereby his own patients may gain in treatment and the whole profession in accurate knowledge. The common cold, the "bilious attack," the mild "rheumatism"—these and a hundred other common affections await the close, constant, and scientific study of the general practitioner.

◆

# Chloroma.

THE meeting of the Edinburgh Medico-Chirurgical Society[1] held on Feb. 5th proved of unusual interest. The chief subject brought before the notice of the society was the rare condition known as chloroma. Papers were read on this subject by Dr. G. H. MELVILLE DUNLOP and Dr. BYROM BRAMWELL.

Chloroma has always been considered a very rare disease, only some 25 cases having been recorded, but Dr. BRAMWELL suggests that it is probably much more common than is usually supposed. He referred to cases in which no definite diagnosis had been made, but which from the descriptions he judged to be cases of chloroma. Dr. BRAMWELL is very probably correct. A similar course of events has not infrequently happened in connexion with other conditions. For instance, it has been clearly shown that actinomyces is more common than was at one time thought, and as soon as the true characteristics of the disease became known it naturally was more frequently recognised. Dr. BRAMWELL very lucidly pointed out the principal features of chloroma, which are: (1) the presence of lymphoid deposits in the orbits, temporal fossæ, and periosteum of the bones of the skull, and the symptoms and signs resulting therefrom; (2) the green colour of the lesions, this being the remarkable peculiarity of the disease; (3) a profound blood change, characterised by anæmia, cachexia, hæmorrhages into the skin, bleedings from the mucous membranes, especially epistaxis, and petechial extravasations into the retinæ and internal surfaces; and (4) changes in the bone-marrow, the spleen, the lymphatic glands, and the organs throughout the body similar to those found in lymphatic leukæmia, that is to say, infiltration with lymphoid deposits.

The term "chloroma" or "green cancer" sufficiently indicates one of the above characteristics. As Dr. DUNLOP stated, the cause of the green colour is unknown. No bile pigment has ever been discovered in any of the tumours. Professor DITTRICH has suggested that it is due to decomposition, but as the colour is confined to the tumour and appears during life, this view is hardly tenable. Professor HUBER made an elaborate investigation on fresh tumours to discover the source of the colour. He ascribed it to minute over those of last year. The receipts are exclusive of the amounts collected by the Coronation Gift Committee. The League of Mercy had contributed £7000, being an increase of £1000 on the contribution for 1900. Excluding the Jubilee year the total receipts of the Fund were: for 1898, £39,272; 1899, £48,536; 1900, £51,549; and 1901, £53,188. With the exception of the £1000 entrusted to the Fund by the London parochial charities for distribution among convalescent homes the grants had been confined to hospitals, and it had still been deemed necessary to restrict the operations of the Fund to institutions situated within the seven-mile radius of Charing-cross. The total cost of collection and distribution for the year 1901 amounted to less than £1800, or under 3½ per cent. of the total collected. £51,000 were distributed, which sum is £1000 more than that distributed last year. It is satisfactory to know that, as His Royal Highness pointed out, the income of the Fund for the last four years has shown a steady increase. Nevertheless, the income is far short of that hoped for by the King when he first inaugurated the Fund in 1897, and the Prince of Wales hopes that the permanent income of the Fund will be increased to £40,000 or £50,000 a year.

## THE INSTITUTE OF CHEMISTRY ON THE APPOINTMENT AND QUALIFICATIONS OF PUBLIC ANALYSTS.

AT the twenty-fourth annual general meeting of the Institute of Chemistry of Great Britain and Ireland held at 30, Bloomsbury-square, London, W.C., on March 3rd, Professor J. Millar Thomson, LL.D., F.R.S., the President, delivered an address dealing with the work of the Institute during the past year. From this it appears that the roll of members has increased by 36, making a total of 1040 Fellows and Associates at present on the register, while there are 130 students in course of training at the colleges and institutions recognised by the council of the Institute. An examination in biological chemistry has been established by means of which the council hopes to encourage analytical chemists to pursue the study of bacteriology and thus be able to deal with chemical work involving bacteriological knowledge. The examination is suited for such as intend to enter the practice of chemistry in its relationship to the chemistry and bacteriology of food, water, sewage, and effluents, and the practical applications of biological chemistry to such industries as brewing, tanning, &c. During the past year the council has ceased to recognise the junior, second class, and lower grade professional preliminary examinations of various examining bodies, and it has now under reconsideration the subjects which shall be compulsory for persons intending to proceed to the examinations of the institute. The council also reported to the members that during the past year it had addressed communications to the Local Government Board and to various county and borough authorities with reference to the combination of the two appointments of medical officer of health and public analyst. The Council maintains that a public analyst requires special training and experience in analytical chemistry far beyond that which is usually acquired by medical practitioners in the course of their professional education. It is true, it is argued, that medical men who take a diploma in Public Health have to undergo a four months' course in physics, chemistry, and microscopy; but while they possess a general knowledge of these subjects considerably greater than that of those medical men not possessing the diploma, yet this knowledge in no way corresponds with that required by the Institute of Chemistry for the Fellowship—viz., a course of two years in the laboratory of an analyst who is a Fellow of the Institute. The council holds the opinion that under the provisions of the Sale of Food and Drugs Act of 1875 it was intended that the medical officer of health and the public analyst for a borough or district should be two distinct persons, inasmuch as the medical officer is one of those officers empowered by the Act to submit suspected samples for analysis. The qualifications and examinations of the Institute are accepted by the Local Government Boards for public analytical appointments, and it is the desire of the council that no lower standard of chemical training and experience than that prescribed by the Institute of Chemistry should be accepted for such important and responsible public appointments as those of public analysts under the Sale of Food and Drugs Act—a desire which we share.

## THE NAVAL ESTIMATES.

AN examination of the Naval Estimates shows that it is proposed substantially to increase from April 1st the pay of all naval medical officers except deputy inspectors-general (why are they neglected?). The old and new scales of pay are as under:—

| — | Old. | New. |
|---|---|---|
| Medical Director-General .. ... | £1300 a year. | £1700 a year. |
| Inspector-General ... ... .. ... | £1003 " | £1300 " |
| Deputy Inspector-General ... ... | £767 " | £767 " |
| Fleet Surgeons... ... ... ... .. | 27/- to 33/- a day. | 30/- to 36/- a day. |
| Staff Surgeons... ... ... . ... | 21/- " 24/- " | 24/- " 27/- " |
| Surgeons ... ... .. ... ... ... | 11/6 " 15/6 " | 14/- " 20/- " |

Thus all below the rank of deputy inspector-general get a satisfactory increment of £50 a year when on full pay. "Half-pay" remains at its old figure. We hope that this change will secure for the navy a sufficient supply of competent surgeons to make up the difference between the 301 who are needed and the 283 already in the service.

## A CORONER ON PROPRIETARY MEDICINES: "MRS. WINSLOW'S SOOTHING SYRUP."

MR. A. BRAXTON HICKS, coroner for Mid-Surrey, who is also the honorary secretary of the Coroners' Society, held an inquest at Kingston recently on the body of Alice Thurley, aged one year and seven months, daughter of Ernest Thurley, a licensed victualler, of Canbury-passage, Kingston. The mother said that the child had been healthy until recently when she was troubled with her teeth; she had also had two convulsions from which she had recovered. Witness had occasionally given her a little of "Mrs. Winslow's soothing syrup" and some of "Dr. Stedman's teething powders." She had not observed that there was a notice on the bottle of the former stating that it was poison. The coroner then sent his officer to borrow a bottle of the medicine from a druggist. The coroner: "You followed what is in the advertisements?" The witness: "Yes." The coroner: "I know. 'And the little cherub wakes up as bright as a button.'" Continuing, the coroner said that it was hard for him to have to drive such things into people, but he had to do it. The mixture contained morphine. The label said that it was a blessing to mothers and good for teething. The coroner (reading the circular wrapped round the bottle): "Oh, this is disgraceful. 'Mrs. Winslow, an experienced nurse and female physician, presents to the attention of mothers her soothing syrup for children teething, which greatly facilitates the process of teething and will allay pain.' I do not know how old Mrs. Winslow is now, but this has been going on for some years, and she ought to be dead and buried by this time. Oh, here we are: 'We have put up and charged with spores. The contrast observed between wood and thick cloth on the one hand, and linen and paper on the other, probably finds explanation in the fact that the *materies morbi* soaked into the fabrics first named, whereas in the case of linen and paper the organisms were limited to the surface and were therefore more exposed to the action of the disinfectant. Apparently in one experiment the feebly resistant bacillus typhosus exposed on wood or cloth was not destroyed by formaldehyde, although it is suggested that some experimental error might have occurred. The organism, however, was destroyed under similar conditions of experiment by sulphur dioxide. We cannot quite gather whether moisture was used in conjunction with this gas which was obtained by burning ordinary sulphur. It is a question whether dry sulphur dioxide could be expected to act upon dried infectious matter, whereas in the case of wet cultures it would be almost certain to succeed in destroying the organism In the case of tuberculous sputum dried on linen and paper formaldehyde showed to greater advantage than sulphur dioxide. Was the formaldehyde accompanied by water vapour? With regard to fluid disinfectants corrosive sublimate (1 in 1000) with 24 hours' exposure destroyed all microbes, including the spores of anthrax and the tubercle bacilli; a 5 per cent. solution of carbolic acid with the same exposure failed to destroy anthrax spores but was destructive to all others; and Condy's fluid (permanganate of soda) failed even when a solution was used containing five teaspoonfuls to the pint. Bleaching powder, "generally speaking" (to use the words of Mr. SHIRLEY MURPHY's summary), only destroyed the less resistant form of microbes, though in the case of anthrax spores on paper and on linen this substance proved more effective than carbolic acid In regard, however, to the experiments in which bleaching powder failed we think that this result is possibly discounted by the fact that though a solution containing a known quantity of bleaching powder was employed yet nowhere can we find that the actual strength of the bleaching powder in terms of available chlorine was ascertained. This is important, for commercial bleaching powder frequently consists of little else than inert chloride and carbonate of calcium, the active chlorine being spent

Coming to specific instances of germicidal power it may be stated that the typhoid bacillus was killed by all the disinfectants except Condy's fluid and bleaching powder. Condy's fluid gave a negative result in each experiment, and bleaching powder used for the disinfection of wood and cloth infected with this organism failed with one hour's exposure but was efficacious on 24 hours' exposure. The bacillus diphtheriæ was killed by formaldehyde and sulphur dioxide. The vibrio of cholera was in each experiment destroyed by all the disinfectants except by Condy's fluid and bleaching powder. Condy's fluid was practically of negative value, and bleaching powder was not always efficacious on one hour's exposure but was successful with 24 hours' exposure. Bacillus pyocyaneus was acted upon in much the same way. It was killed in each experiment by all except Condy's fluid and bleaching powder. Staphylococcus aureus was also killed in each experiment by all except Condy's fluid and bleaching powder. Anthrax spores were only destroyed with certainty by perchloride of mercury, the other disinfectants either failing on each occasion or being uncertain, and almost invariably failing when wood and cloth were the materials to be disinfected. For tubercle bacilli carbolic acid and perchloride of mercury proved to be the only real germicides on each occasion. Condy's fluid and sulphur dioxide were of negative value and the other disinfectants were uncertain. These results are obviously of great importance, for they have an official standing, and they should raise the actual practice of disinfection to a much more satisfactory position.

# Annotations.

"Ne quid nimis."

## THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

WE understand that rapid progress is being made with the preliminaries of the Fourteenth International Congress of Medicine, which will be held in Madrid under the patronage of the King and the Queen Regent from April 23rd to the 30th, 1903. The Spanish Minister of Foreign Affairs has invited all the Governments of other countries to send representatives, and an invitation of a like nature has been sent to all universities and schools of medicine and to the principal medical societies of all countries. The work of the Congress will be distributed over the following 16 Sections: Anatomy (descriptive, comparative, &c.), Physiology (including Biology), General Pathology (including Bacteriology), Therapeutics (including Hydrology and Pharmacy), Internal Pathology, Nervous Disorders (including Insanity and Criminal Anthropology), Diseases of Children, Dermatology (including Syphilography), General Surgery, Ophthalmology, Oto-Rhino-Laryngology, Odontology, Obstetrics (including Gynæcology), Military and Naval Medicine, Public Health, and Legal Medicine (including Toxicology). The President is Dr. Julián Calleja, and the general secretary is Dr. Angel Fernández-Caro. Medical practitioners, pharmaceutical chemists, and veterinary surgeons are eligible as members of the Congress. Applications should be sent as early as possible to the general secretary at the Faculty of Medicine, Madrid. It is requested that they may be clearly written, and they should give the names, titles, qualifications, and addresses of the writers; a cheque on Madrid for 30 pesetas (from 19*s.* to 20*s.*, according to the current rate of exchange) should accompany them. Intending members are at the same time requested to specify the section which they wish to join; they will be entitled to receive a copy of the Transactions of this section, and will at the same time be at full liberty to take part in the business of any other section. For 12 pesetas ladies accompanying members may obtain a special card of admission to official entertainments Communications relating to the work of the Congress should reach the executive committee before Jan 1st, 1903. The official languages will be Spanish, French, English, and German.

## KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE Prince of Wales presided at the annual meeting of King Edward's Hospital Fund for London, held at York House, St. James's, on March 7th. The report of the General Council, which on the motion of His Royal Highness was adopted, stated that steady and continuous progress marked once again the result of the past year's work. The total receipts for the year had again shown an increase over those of last year. The receipts are exclusive of the amounts collected by the Coronation Gift Committee. The League of Mercy had contributed £7000, being an increase of £1000 on the contribution for 1900. Excluding the Jubilee year the total receipts of the Fund were: for 1898, £39,272; 1899, £48,536; 1900, £51,549; and 1901, £53,188 With the exception of the £1000 entrusted to the Fund by the London parochial charities for distribution among convalescent homes the grants had been confined to hospitals, and it had still been deemed necessary to restrict the operations of the Fund to institutions situated within the seven-mile radius of Charing-cross. The total cost of collection and distribution for the year 1901 amounted to less than £1800, or under 3½ per cent. of the total collected. £51,000 were distributed, which sum is £1000 more than that distributed last year. It is satisfactory to know that, as His Royal Highness pointed out, the income of the Fund for the last four years has shown a steady increase. Nevertheless, the income is far short of that hoped for by the King when he first inaugurated the Fund in 1897, and the Prince of Wales hopes that the permanent income of the Fund will be increased to £40,000 or £50,000 a year.

## THE INSTITUTE OF CHEMISTRY ON THE APPOINTMENT AND QUALIFICATIONS OF PUBLIC ANALYSTS.

At the twenty-fourth annual general meeting of the Institute of Chemistry of Great Britain and Ireland held at 30, Bloomsbury-square, London, W.C., on March 3rd, Professor J. Millar Thomson, LL D., F.R.S., the President, delivered an address dealing with the work of the Institute during the past year. From this it appears that the roll of members has increased by 36, making a total of 1040 Fellows and Associates at present on the register, while there are 130 students in course of training at the colleges and institutions recognised by the council of the Institute. An examination in biological chemistry has been established by means of which the council hopes to encourage analytical chemists to pursue the study of bacteriology and thus be able to deal with chemical work involving bacteriological knowledge. The examination is suited for such as intend to enter the practice of chemistry in its relationship to the chemistry and bacteriology of food, water, sewage, and effluents, and the practical applications of biological chemistry to such industries as brewing, tanning, &c. During the past year the council has ceased to recognise the junior, second class, and lower grade professional preliminary examinations of various examining bodies, and it has now under reconsideration the subjects which shall be compulsory for persons intending to proceed to the examinations of the institute The council also reported to the members that during the past year it had addressed communications to the Local Government Board and to various county and borough authorities with reference to the combination of the two appointments of medical officer of health and public analyst. The Council maintains that a public analyst requires special training and experience in analytical chemistry far beyond that which is usually acquired by medical practitioners in the course of their professional education. It is true, it is argued, that medical men who take a diploma in Public Health have to undergo a four months' course in physics, chemistry, and microscopy; but while they possess a general knowledge of these subjects considerably greater than that of those medical men not possessing the diploma, yet this knowledge *in no way corresponds with that* required by the Institute of Chemistry for the Fellowship—viz., a course of two years in the laboratory of an analyst who is a Fellow of the Institute. The council holds the opinion that under the provisions of the Sale of Food and Drugs Act of 1875 it was intended that the medical officer of health and the public analyst for a borough or district should be two distinct persons, inasmuch as the medical officer is one of those officers empowered by the Act to submit suspected samples for analysis. The qualifications and examinations of the Institute are accepted by the Local Government Boards for public analytical appointments, and it is the desire of the council that no lower standard of chemical training and experience than that prescribed by the Institute of Chemistry should be accepted for such important and responsible public appointments as those of public analysts under the Sale of Food and Drugs Act—a desire which we share.

## THE NAVAL ESTIMATES.

An examination of the Naval Estimates shows that it is proposed substantially to increase from April 1st the pay of all naval medical officers except deputy inspectors-general (why are they neglected ?). The old and new scales of pay are as under:—

| — | Old. | New. |
|---|---|---|
| Medical Director-General ... ... | £1300 a year. | £1700 a year. |
| Inspector General ... .. .. .. ... | £1003 ,, | £1300 ,, |
| Deputy Inspector-General ... ... | £767 ,, | £767 ,, |
| Fleet Surgeons .. ... ... ... ... | 27/- to 33/- a day. | 30/- to 36/- a day. |
| Staff Surgeons .. .. .. ... .. ... | 21/- ,, 24/- ,, | 24/- ,, 27/- ,, |
| Surgeons ... ... .. ... ... ... | 11/6 ,, 15/6 ,, | 14/- ,, 20/- ,, |

Thus all below the rank of deputy inspector-general get a satisfactory increment of £50 a year when on full pay. "Half-pay" remains at its old figure. We hope that this change will secure for the navy a sufficient supply of competent surgeons to make up the difference between the 301 who are needed and the 283 already in the service.

## A CORONER ON PROPRIETARY MEDICINES: "MRS. WINSLOW'S SOOTHING SYRUP."

Mr. A. Braxton Hicks, coroner for Mid-Surrey, who is also the honorary secretary of the Coroners' Society, held an inquest at Kingston recently on the body of Alice Thurley, aged one year and seven months, daughter of Ernest Thurley, a licensed victualler, of Canbury-passage, Kingston. The mother said that the child had been healthy until recently when she was troubled with her teeth: she had also had two convulsions from which she had recovered. Witness had occasionally given her a little of "Mrs. Winslow's soothing syrup" and some of "Dr. Stedman's teething powders." She had not observed that there was a notice on the bottle of the former stating that it was poison. The coroner then sent his officer to borrow a bottle of the medicine from a druggist. The coroner: "You followed what is in the advertisements?" The witness: "Yes." The coroner: "I know. 'And the little cherub wakes up as bright as a button.'" Continuing, the coroner said that it was hard for him to have to drive such things into people, but he had to do it. The mixture contained morphine. The label said that it was a blessing to mothers and good for teething. The coroner (reading the circular wrapped round the bottle): "Oh, this is disgraceful. 'Mrs. Winslow, an experienced nurse and female physician, presents to the attention of mothers her soothing syrup for children teething, which greatly facilitates the process of teething and will allay pain.' I do not know how *old* Mrs. Winslow is now, but this has been going on for some years, and she ought to be dead and buried by this time. Oh, here we are: 'We have put up and sold this article for over 50 years and can say in confidence and truth of it what we have never been able to say of any other medicine—never has it failed in a single instance to effect a cure.' That is a good drug, that is. 'Never did we know an instance of dissatisfaction by anyone who used it. All speak in terms of highest commendation of its magical effects and medical cures. This valuable preparation is the prescription of one of the most skilful nurses in America.' Oh, it comes from America, does it; well, I am glad to hear that." Continuing, the coroner said that he had had an analysis made of the stuff. In the old days it was the habit in Lincolnshire for mothers to give their children opium to keep them quiet. Magistrates had put a stop to that, and then some ingenious persons invented some stuff which contained morphia and called it soothing syrup. They sold it for a long time till he was able to get an analysis and then it was found to contain morphia and the company had to put a "poison" label on the bottle. It was done in small letters which could hardly be seen. It was a question whether it was not wrong to give children a narcotic at all. After reading the directions for administering the medicine the coroner said that seeing that a teaspoonful was prescribed for a baby six months old an adult would want a whole bottle. "Gentlemen," said the coroner to the jury, "we suffer from dyspepsia and other complaints, why cannot we have a cure like this?" adding that if anyone took the trouble to read the advertisements they would see that they were rubbish. He did not blame the mother of the child but the people who advised her to use the syrup. Dr. Yeo stated that death was due to heart failure brought on by acute pneumonia. Replying to the coroner he said that morphia would have the effect of depressing the heart's action, and anything containing it would be a bad thing for children with lung trouble. The coroner, in summing up, said that it was a very curious thing that the last time he held an inquest in Kingston he had before him a case in which patent medicines were concerned. This was a proprietary medicine, the contents of which could only be ascertained by analysis, as he had had done in the case of "Mrs. Winslow's soothing syrup." Long advertisements were to be found in the papers of these medicines, and he could only say that they were a fraud on the people who read them. The jury returned a verdict of "Death from natural causes," and added a rider to the effect that these medicines which contained poison should be marked in red ink. The coroner said that the jury did not wish to blame the parents. He would keep pegging away about medicines of that sort until something was done.

## IS THE MUSHROOM NUTRITIOUS?

THE notion has long been held that the mushroom presented the composition of animal flesh, which led to it being called the "vegetable beef-steak." It appears, however, that this conclusion has been based on some analyses made many years ago when analytical methods were not as exact as they are now and when the chemistry of food was not so well understood. In one regard, at any rate, the mushroom does resemble a beef-steak—in that it contains practically the same amount of water. But the dry solid constituents of the mushroom differ very materially in kind from the solids of meat. The most important difference is due to the rich proportion of proteids—the so-called flesh-formers—in meat as compared with the feeble amount in the mushroom. This fact, as ascertained by recent analyses, hardly justifies the mushroom being regarded as a "vegetable beef-steak." It may be a blow to the vegetarian, but he would have to consume at least 10 pounds of mushrooms in order to gain the equivalent of a little over one pound of prime beef. Indeed, in the light of modern inquiry there seems to be no reason for believing that mushrooms possess any greater food value than other ordinary fresh vegetable foods, and in many respects they compare unfavourably with them. Still, the fresh tender mushroom is undoubtedly easily digestible, and as it contains carbohydrates in addition to some proteid it is obvious that it is of some dietetic value. This value is not comparable with that possessed by essential foods such as meat, milk, and eggs. The mushroom, however, contains an unusual proportion of potassium salts. Few will deny that the mushroom is an excellent adjunct to many dishes; it has an appetising flavour, and this quality alone makes it dietetically valuable.

## MEMORIAL TO THE LATE SIR WILLIAM MAC CORMAC, BART., K.C.B., K.C.V.O.

AT a meeting of the members of St. Thomas's Hospital and Medical School held on March 11th, the Treasurer of the hospital in the chair, it was decided that steps should be taken to institute a permanent memorial of the connexion of the late Sir William Mac Cormac with the institution. A general committee of the members of the hospital and medical school has been formed and already consists of 250 St. Thomas's men. An executive committee was selected from this body, empowered to solicit subscriptions, its first object being to arrange for the production of a bust of Sir William Mac Cormac to be placed in the central hall of the hospital. It was further decided that in the event of the amount of money collected being in excess of the sum requisite for the bust a special meeting of the general committee should be called in the future to decide in what manner the surplus should be applied. The executive committee selected consists of the Treasurer of the hospital, Mr. J. G. Wainwright; two governors, Mr. Henry Bonham-Carter and Mr. T. Du Buisson; the senior physician, Dr. S. J. Sharkey; the senior surgeon, Mr. H. H. Clutton; the dean of the medical school, Dr. H. G. Turney; and four representatives of the school from London and the provinces, Mr. Thomas Wakley, jun., Mr. S. Osborn, Mr. George Wherry, and Mr. G. C. Franklin. Mr. G. H. Makins, C.B., and Mr. F. C. Abbott will act as secretaries to the committee.

## VACCINATION AT HELSTON, CORNWALL.

EPIDEMICS have their uses although they are hard taskmasters. The present outbreak of small-pox in London has been the means of making obvious the inconveniences which occasionally arise from the fact of sanitary and preventive measures being in the hands of two different bodies. Thus at Helston there is friction between the town council, who are also the sanitary authority, and the guardians, who are the vaccination authorities, on the matter of vaccination. It appears that recently the council, remembering how severely the town suffered from small-pox about 30 years ago, on the advice of their medical officer of health (Mr. W. Wearne) decided to draw attention to the advantages of vaccination. Placards were displayed in the town and handbills were distributed at houses urging the vaccination of children and the revaccination of persons over 10 years of age. These notices annoyed the guardians and they seem to imagine that Mr. W. Wearne, who is also public vaccinator for a district which includes the borough of Helston, is responsible for them. At the meeting of the council held on Feb. 27th Mr. Wearne reported that he had performed over 300 vaccinations and would have done many more only that people were afraid that unless they paid the fees themselves their names would be posted in the town as paupers, the guardians having threatened to do so. The town clerk remarked that the guardians would not dare to act in such a manner, the mayor adding that the council had only performed their obvious duty. One of the aldermen stated that it was not so much vaccination which the guardians objected to as to the account of the public vaccinator, which amounted to £50. A copy of the notices issued with a statement of what had been done had been sent by the council to the Local Government Board. The guardians have served Mr. Wearne and the other public vaccinators of their union with a notice that their services as such will not be required at the end of 28 days from the date of notification. The poster which has so offended the guardians simply stated the advantages of vaccination and revaccination and pointed out that anyone could be vaccinated free of charge by the public vaccinator either at the surgery or at his (the patient's) own house. As for the nonsense which was talked by some people that any person who appeared on the list of those publicly vaccinated would be a pauper, this is simply a device to discredit vaccination. A man is no more made a pauper by being vaccinated by the public vaccinator than he is by being notified to the medical officer of health as having scarlet fever or by taking a book out of a public library. In all these cases he, or his medical attendant, receives benefits which are paid for out of the rates. The guardians have a right to keep a list of those vaccinated by the public vaccinator, but no one has any right to make use of this list as a threat. It is right that the whereabouts of the public vaccinator should be made as public as possible in a time of epidemic, but any public vaccinator should be careful to avoid the appearance of attracting other practitioners' patients. At a meeting of the guardians held on March 1st it was resolved that the medical officers and public vaccinators should be asked to talk matters over with the board. We learn that an interview has been held between the public vaccinators and the Finance Committee of the board of guardians. The result will not be made public until the board has considered the report of the committee.

## CONVERSION OF HODGKIN'S DISEASE INTO LEUKÆMIA: LEUKÆMIC LESIONS IN THE SKIN.

THE nature of leukæmia and lymphadenoma and their relation to one another still remain difficult and unsolved problems and any exceptional facts which increase our knowledge are valuable In the *American Journal of the Medical Sciences* for December, 1901, Dr. G. W. Wende has recorded the following remarkable case. A man, aged 26 years, came under observation on April 26th, 1900. On Dec. 1st, 1899, he accidentally noticed slight induration of the skin over the left temple It slowly increased and in two months attained the size of a florin. The centre of the cheek on the same side then became affected. A hide-bound sensation was felt whenever the jaw was moved and the pre-auricular lymphatic glands became enlarged. Then the post-auricular, the inferior maxillary, and the cervical glands were affected and in this order. On Feb. 20th, 1900, a number of superficial, irregular, yellowish-grey spots were detected over the sternum and there was a slight infiltration near the left nipple. Other spots appeared on the chest and back. The axillary glands became enlarged and tender. Examination of the blood showed no marked alterations (erythrocytes 5,128,000, leucocytes 4000, hæmoglobin 88 per cent., small lymphocytes 27 per cent , large and transitional lymphocytes 4 per cent , polymorphonuclear neutrophiles 68 per cent., and eosinophiles 1 per cent ). The initial lesion on the left temple formed an oval, dusky protuberance 10 centimetres in diameter, non-adherent to the deep parts. The centre of the left cheek bore a deep-seated infiltration from three and a half to four centimetres in diameter. In the left inframammary region were two lumps of about the size of a filbert covered by normal skin. Around the nipple was a large patch similar to that on the temple. On the lower abdomen were seven deep-seated nodules varying in size from that of a pea to that of a hickory nut. The largest was cyanotic and brown. The whole of the chest and back was mottled with numerous pigmentary stains and blotches, principally of a chocolate colour. All the superficial lymphatic glands were enlarged, the cervical most, and those on the left side of the body more than those on the right. Six minims of Fowler's solution were injected daily and the dose was increased by two drops weekly. In three weeks improvement was evident, new lesions ceased to form, and the old ones diminished. After six weeks the skin was normal except for the pigmentation. But on July 1st a growth suddenly appeared on the scalp and two on the back. On the 10th the patient had lost strength and was drowsy. The mucous membranes were becoming pale and the glands were increasing in size. Petechiæ appeared on the shoulders. Fresh hæmorrhages occurred daily on the back and chest. Retinal hæmorrhages were seen. Examination of the blood on July 10th showed the following condition: hæmoglobin, 40 per cent. ; red corpuscles 1,936,000, white corpuscles 34,000, macrocytes and microcytes in moderate numbers, a few poikilocytes, and 102 normoblasts to the cubic millimetre ; small lymphocytes, 95 5 per cent. ; large lymphocytes, 0 7 per cent. ; eosinophiles, 0 4 per cent. ; and polymorphonuclear neutrophiles, 3 4 per cent. The spleen was enlarged. The gums were blue, swollen, and spongy. The tonsils became enlarged until they impinged on one another. The gums swelled until they nearly covered the teeth and became ulcerated. Death occurred on July 30th. The necropsy showed the pleuræ to be studded with lymphatic nodules. The peribronchial glands varied in size from that of a pea to that of a chestnut. The lymphatic follicles of the stomach and intestines and the mesenteric glands were enlarged. The spleen weighed 1500 grammes. Microscopical examination of the cutaneous lesions showed that they consisted of lymphoid cells in the cutis and subcutaneous tissue. The cellular elements of the lymphatic glands were greatly increased. The spleen showed similar changes. The Malpighian bodies were often twice the normal size and the pulp was crowded with lymphocytes. In the bone marrow lymphocytes were present but were not conspicuous. The liver and kidneys showed lymphatic infiltration. Cases of leukæmic infiltration of the skin have been observed since 1876 by Bisiadecki, Hochsinger, Schiff, Phillipert, and Oliver. Kreibich has reported a case in which pendulous masses, varying in size from that of a pigeon's egg to that of an adult fist, were found on the face, which in the majority of cases was the seat of invasion As the blood was normal at the first examination Dr. Wende regards the case narrated above as an example of the conversion of Hodgkin's disease into leukæmia, an exceedingly rare occurrence.

## THE ESSAYS AND ADDRESSES OF SIR JAMES PAGET.

ALL men of science will be glad to hear that a collection of selected essays and addresses by the late Sir James Paget has just appeared. The collection is edited by his son, Mr. Stephen Paget, and the publishers are Messrs. Longmans, Green, and Co. Some of the essays are apparently hitherto unpublished. The others have appeared in our own columns, in those of the *British Medical Journal*, in St. Bartholomew's Hospital Reports, in the "Clinical Lectures and Essays," in "Studies of Old Case-books," in the Transactions of the Royal Medical and Chirurgical Society, and in monthly reviews. There are also addresses, such as the Presidential Address at the International Medical Congress of 1881, the sold this article for over 50 years and can say in confidence and truth of it what we have never been able to say of any other medicine—never has it failed in a single instance to effect a cure.' That is a good drug, that is. 'Never did we know an instance of dissatisfaction by anyone who used it. All speak in terms of highest commendation of its magical effects and medical cures. This valuable preparation is the prescription of one of the most skilful nurses in America.' Oh, it comes from America, does it; well, I am glad to hear that." Continuing, the coroner said that he had had an analysis made of the stuff. In the old days it was the habit in Lincolnshire for mothers to give their children opium to keep them quiet. Magistrates had put a stop to that, and then some ingenious persons invented some stuff which contained morphia and called it soothing syrup. They sold it for a long time till he was able to get an analysis and then it was found to contain morphia and the company had to put a "poison" label on the bottle. It was done in small letters which could hardly be seen. It was a question whether it was not wrong to give children a narcotic at all. After reading the directions for administering the medicine the coroner said that seeing that a teaspoonful was prescribed for a baby six months old an adult would want a whole bottle. "Gentlemen," said the coroner to the jury, "we suffer from dyspepsia and other complaints, why cannot we have a cure like this?" adding that if anyone took the trouble to read the advertisements they would see that they were rubbish. He did not blame the mother of the child but the people who advised her to use the syrup. Dr. Yeo stated that death was due to heart failure brought on by acute pneumonia. Replying to the coroner he said that morphia would have the effect of depressing the heart's action, and anything containing it would be a bad thing for children with lung trouble. The coroner, in summing up, said that it was a very curious thing that the last time he held an inquest in Kingston he had before him a case in which patent medicines were concerned. This was a proprietary medicine, the contents of which could only be ascertained by analysis, as he had had done in the case of "Mrs. Winslow's soothing syrup." Long advertisements were to be found in the papers of these medicines, and he could only say that they were a fraud on the people who read them. The jury returned a verdict of "Death from natural causes," and added a rider to the effect that these medicines which contained poison should be marked in red ink. The coroner said that the jury did not wish to blame the parents. He would keep pegging away about medicines of that sort until something was done.

## IS THE MUSHROOM NUTRITIOUS?

THE notion has long been held that the mushroom presented the composition of animal flesh, which led to it being called the "vegetable beef-steak." It appears, however, that this conclusion has been based on some analyses made many years ago when analytical methods were not as exact as they are now and when the chemistry of food was not so well understood. In one regard, at any rate, the mushroom does resemble a beef-steak—in that it contains practically the same amount of water. But the dry solid constituents of the mushroom differ very materially in kind from the solids of meat. The most important difference is due to the rich proportion of proteids—the so-called flesh-formers—in meat as compared with the feeble amount in the mushroom. This fact, as ascertained by recent analyses, hardly justifies the mushroom being regarded as a "vegetable beef-steak." It may be a blow to the vegetarian, but he would have to consume at least 10 pounds of mushrooms in order to gain the equivalent of a little over one pound of prime beef. Indeed, in the light of modern inquiry there seems to be no reason for believing that mushrooms possess any greater food value than other ordinary fresh vegetable foods, and in many respects they compare unfavourably with them. Still, the fresh tender mushroom is undoubtedly easily digestible, and as it contains carbohydrates in addition to some proteid it is obvious that it is of some dietetic value. This value is not comparable with that possessed by essential foods such as meat, milk, and eggs. The mushroom, however, contains an unusual proportion of potassium salts. Few will deny that the mushroom is an excellent adjunct to many dishes; it has an appetising flavour, and this quality alone makes it dietetically valuable.

## MEMORIAL TO THE LATE SIR WILLIAM MAC CORMAC, BART., K.C.B., K.C.V.O.

AT a meeting of the members of St. Thomas's Hospital and Medical School held on March 11th, the Treasurer of the hospital in the chair, it was decided that steps should be taken to institute a permanent memorial of the connexion of the late Sir William Mac Cormac with the institution. A general committee of the members of the hospital and medical school has been formed and already consists of 250 St. Thomas's men. An executive committee was selected from this body, empowered to solicit subscriptions, its first object being to arrange for the production of a bust of Sir William Mac Cormac to be placed in the central hall of the hospital. It was further decided that in the event of the amount of money collected being in excess of the sum requisite for the bust a special meeting of the general committee should be called in the future to decide in what manner the surplus should be applied. The executive committee selected consists of the Treasurer of the hospital, Mr. J. G. Wainwright; two governors, Mr. Henry Bonham-Carter and Mr. T. Du Buisson; the senior physician, Dr. S. J. Sharkey; the senior surgeon, Mr. H. H. Clutton; the dean of the medical school, Dr. H. G. Turney; and four representatives of the school from London and the provinces, Mr. Thomas Wakley, jun., Mr. S. Osborn, Mr. George Wherry, and Mr. G. C. Franklin. Mr. G. H. Makins, C.B., and Mr. F. C. Abbott will act as secretaries to the committee.

## VACCINATION AT HELSTON, CORNWALL.

EPIDEMICS have their uses although they are hard taskmasters. The present outbreak of small-pox in London has been the means of making obvious the inconveniences which occasionally arise from the fact of sanitary and preventive measures being in the hands of two different bodies. Thus at Helston there is friction between the town council, who are also the sanitary authority, and the guardians, who are the vaccination authorities, on the matter of vaccination. It appears that recently the council, remembering how severely the town suffered from small-pox about 30 years ago, on the advice of their medical officer of health (Mr. W. Wearne) decided to draw attention to the advantages of vaccination. Placards were displayed in the town and handbills were distributed at houses urging the vaccination of children and the revaccination of persons over 10 years of age. These notices annoyed the guardians and they seem to imagine that Mr. W. Wearne, who is also public vaccinator for a district which includes the borough of Helston, is responsible for them. At the meeting of the council held on Feb 27th Mr. Wearne reported that he had performed over 300 vaccinations and would have done many more only that people were afraid that unless they paid the fees themselves their names would be posted in the town as paupers, the guardians having threatened to do so. The town clerk remarked that the guardians would not dare to act in such a manner, the mayor adding that the council had only performed their obvious duty. One of the aldermen stated that it was not so much vaccination which the guardians objected to as to the account of the public vaccinator, which amounted to £50. A copy of the notices issued with a statement of what had been done had been sent by the council to the Local Government Board. The guardians have served Mr. Wearne and the other public vaccinators of their union with a notice that their services as such will not be required at the end of 28 days from the date of notification. The poster which has so offended the guardians simply stated the advantages of vaccination and revaccination and pointed out that anyone could be vaccinated free of charge by the public vaccinator either at the surgery or at his (the patient's) own house. As for the nonsense which was talked by some people that any person who appeared on the list of those publicly vaccinated would be a pauper, this is simply a device to discredit vaccination. A man is no more made a pauper by being vaccinated by the public vaccinator than he is by being notified to the medical officer of health as having scarlet fever or by taking a book out of a public library. In all these cases he, or his medical attendant, receives benefits which are paid for out of the rates. The guardians have a right to keep a list of those vaccinated by the public vaccinator, but no one has any right to make use of this list as a threat. It is right that the whereabouts of the public vaccinator should be made as public as possible in a time of epidemic, but any public vaccinator should be careful to avoid the appearance of attracting other practitioners' patients. At a meeting of the guardians held on March 1st it was resolved that the medical officers and public vaccinators should be asked to talk matters over with the board. We learn that an interview has been held between the public vaccinators and the Finance Committee of the board of guardians. The result will not be made public until the board has considered the report of the committee.

## CONVERSION OF HODGKIN'S DISEASE INTO LEUKÆMIA: LEUKÆMIC LESIONS IN THE SKIN.

THE nature of leukæmia and lymphadenoma and their relation to one another still remain difficult and unsolved problems and any exceptional facts which increase our knowledge are valuable. In the *American Journal of the Medical Sciences* for December, 1901, Dr. G. W. Wende has recorded the following remarkable case. A man, aged 26 years, came under observation on April 26th, 1900. On Dec. 1st, 1899, he accidentally noticed slight induration of the skin over the left temple It slowly increased and in two months attained the size of a florin. The centre of the cheek on the same side then became affected. A hide-bound sensation was felt whenever the jaw was moved and the pre-auricular lymphatic glands became enlarged. Then the post-auricular, the inferior maxillary, and the cervical glands were affected and in this order. On Feb. 20th, 1900, a number of superficial, irregular, yellowish-grey spots were detected over the sternum and there was a slight infiltration near the left nipple. Other spots appeared on the chest and back. The axillary glands became enlarged and tender. Examination of the blood showed no marked alterations (erythrocytes 5,128,000, leucocytes 4000, hæmoglobin 88 per cent., small lymphocytes 27 per cent., large and transitional lymphocytes 4 per cent., polymorphonuclear neutrophiles 68 per cent., and eosinophiles 1 per cent.). The initial lesion on the left temple formed an oval, dusky protuberance 10 centimetres in diameter, non-adherent to the deep parts. The centre of the left cheek bore a deep-seated infiltration from three and a half to four centimetres in diameter. In the left inframammary region were two lumps of about the size of a filbert covered by normal skin. Around the nipple was a large patch similar to that on the temple. On the lower abdomen were seven deep-seated nodules varying in size from that of a pea to that of a hickory nut. The largest was cyanotic and brown. The whole of the chest and back was mottled with numerous pigmentary stains and blotches, principally of a chocolate colour. All the superficial lymphatic glands were enlarged, the cervical most, and those on the left side of the body more than those on the right. Six minims of Fowler's solution were injected daily and the dose was increased by two drops weekly. In three weeks improvement was evident, new lesions ceased to form, and the old ones diminished. After six weeks the skin was normal except for the pigmentation. But on July 1st a growth suddenly appeared on the scalp and two on the back. On the 10th the patient had lost strength and was drowsy. The mucous membranes were becoming pale and the glands were increasing in size. Petechiæ appeared on the shoulders. Fresh hæmorrhages occurred daily on the back and chest. Retinal hæmorrhages were seen. Examination of the blood on July 10th showed the following condition: hæmoglobin, 40 per cent.; red corpuscles 1,936,000, white corpuscles 34,000, macrocytes and microcytes in moderate numbers, a few poikilocytes, and 102 normoblasts to the cubic millimetre; small lymphocytes, 95·5 per cent.; large lymphocytes, 0·7 per cent.; eosinophiles, 0·4 per cent.; and polymorphonuclear neutrophiles, 3·4 per cent. The spleen was enlarged. The gums were blue, swollen, and spongy. The tonsils became enlarged until they impinged on one another. The gums swelled until they nearly covered the teeth and became ulcerated. Death occurred on July 30th. The necropsy showed the pleuræ to be studded with lymphatic nodules. The peribronchial glands varied in size from that of a pea to that of a chestnut. The lymphatic follicles of the stomach and intestines and the mesenteric glands were enlarged. The spleen weighed 1500 grammes. Microscopical examination of the cutaneous lesions showed that they consisted of lymphoid cells in the cutis and subcutaneous tissue. The cellular elements of the lymphatic glands were greatly increased. The spleen showed similar changes. The Malpighian bodies were often twice the normal size and the pulp was crowded with lymphocytes. In the bone marrow lymphocytes were present but were not conspicuous. The liver and kidneys showed lymphatic infiltration. Cases of leukæmic infiltration of the skin have been observed since 1876 by Bisiadecki, Hochsinger, Schiff, Phillipert, and Oliver. Kreibich has reported a case in which pendulous masses, varying in size from that of a pigeon's egg to that of an adult fist, were found on the face, which in the majority of cases was the seat of invasion. As the blood was normal at the first examination Dr. Wende regards the case narrated above as an example of the conversion of Hodgkin's disease into leukæmia, an exceedingly rare occurrence.

## THE ESSAYS AND ADDRESSES OF SIR JAMES PAGET.

ALL men of science will be glad to hear that a collection of selected essays and addresses by the late Sir James Paget has just appeared. The collection is edited by his son, Mr. Stephen Paget, and the publishers are Messrs. Longmans, Green, and Co. Some of the essays are apparently hitherto unpublished. The others have appeared in our own columns, in those of the *British Medical Journal*, in St. Bartholomew's Hospital Reports, in the "Clinical Lectures and Essays," in "Studies of Old Case-books," in the Transactions of the Royal Medical and Chirurgical Society, and in monthly reviews. There are also addresses, such as the Presidential Address at the International Medical Congress of 1881, the

Hunterian Oration of 1877, and the Bradshaw Lecture of 1882, which are familiar to a good many who were present at their delivery or who have seen reprints of them, but Sir James Paget is an author who will bear much re reading There is no doubt that the book will be a memorial not only of a great but of a lovable man, such as all who knew him either personally or by repute will be glad to possess In an early issue we hope to give an extended review of the work

## THE PREVALENCE OF SMALL-POX

THE returns of small pox in London for the past week are as follows on Saturday and Sunday, March 8th and 9th, 57 fresh cases in all were notified and removed, on Monday the 10th there were 67 fresh cases, on Tuesday, the 11th there were 76 fresh cases, and on Wednesday, the 12th, there were 52 fresh cases In Glasgow 11 new cases of small pox were admitted to the hospital at Belvidere on March 9th and 9 on the 10th On the same dates 26 patients were dismissed leaving a total of 202 cases still under treatment

## THE TREATMENT OF CUTANEOUS EPITHELIOMA BY THE X RAYS

DR CHARLES WARRENNE ALLEN, Professor of Dermatology in the New York Post-Graduate Medical School, writing in the *New York Medical Record* of Jan 25th expresses the opinion that the x rays will eventually be made serviceable in the treatment of cutaneous epithelioma but at the same time he admits that the method is as yet only in its infancy At present he considers that the proper place of the rays is in the after treatment or as a means of checking extension of the disease In dealing with epithelioma he therefore prefers in the first place to follow the ordinary rules of surgical practice and after an operation has been performed either with the knife or with caustic he strongly recommends that the rays should be applied, not however, to the extent of producing a so called "burn *For the application of the rays, especially to the mouth,* throat uterus, and rectum, he has suggested a funnel shaped metallic cone, into the flare of which the x ray tube is inserted As a source of electrical energy a static machine is preferable for use in an institution or a consulting room but in a patient's house an induction coil is obviously more convenient although, perhaps, inferior from a therapeutic point of view As to the dangers to be apprehended from the application of the x rays he believes them to have been over estimated although it is unquestionable that in incompetent hands much damage may be done by this method of treatment and quacks may be the means of bringing it into some degree of disrepute He dismisses as mistaken the idea that applications of methylene blue used concurrently with x ray treatment interfere with the action of the latter

## THE SALARIES OF ASSISTANT MEDICAL OFFICERS OF THE METROPOLITAN ASYLUMS BOARD

AT a meeting of the Metropolitan Asylums Board held on March 8th the Hospitals Committee sent in a report on the matter of the salaries paid to assistant medical officers The present scale of pay was adopted some eight years ago and the committee considered that the time had arrived for revision All assistant medical officers started at a salary of £160 per annum, increasing by annual rises of £20 per annum to £200 together with board, washing, and attendance The committee now recommended that the salaries should be raised owing to the increase in the cost of medical education and other reasons The senior assistant medical officer should be paid at a higher rate than the junior Their recommendations which were unanimously adopted, may be summarised as follows 1 Senior assistant medical officers to be paid at the rate of £280 per annum for the first year and at the rate of £300 per annum for the second and subsequent years with board, lodging, washing, and attendance. 2 In future all junior assistant medical officers shall be appointed on probation for not more than six months, such appointment to be subject to confirmation or revocation by the Hospitals Committee Salary during this period to be at the rate of £180 per annum, with board, lodging, washing, and attendance If the appointment be confirmed the salary is to be at the rate of £180 per annum, commencing from the beginning of probation and to rise by £20 per annum or at longer intervals to £240 per annum with board, lodging, washing and attendance 3 Assistant medical officers already in the service of the Board are to be classified *according to length of service and from March 25th, 1902* they shall be paid under the new scale

## THE DANGERS OF ACETYLENE

AN important report dealing with the apparatus and material used in the generation of acetylene has recently been printed in a Parliamentary paper The members of the committee seven in number, were all experts—some in regard to explosives others to petroleum, and others to coal gas Of the generators examined not one appeared to be unsatisfactory under the conditions of the test, but, as is pointed out this does not necessarily mean that all the types of generators on the market were safe, for some appliances were withheld because it was felt that they would not pass the test and in some instances serious defects in the design were made good before the generator was submitted to the test The committee states that attention should be given to the following five points in regard to the construction of the generator (1) it should be simple in action and design (2) it should be strongly constructed, (3) it should give a high efficiency as indicated by the yield of gas per unit of carbide, (4) the pressure of gas in the generator should always be low, and (5) *the residue of lime in the generator* should be easily removeable There is obviously no reference here to the purity of the carbide This, it seems to us is an important point, for the ordinary impurities of carbide are compounds which when moistened with water yield two poisonous gases—namely, phosphoretted hydrogen and sulphuretted hydrogen Moreover, it is possible that the presence of impurities in carbide might render the gases generated from it spontaneously inflammable

## THE SYMPTOMATOLOGY OF SYPHILITIC SPASMODIC PARAPLEGIA

AT the meeting of the Société Médicale des Hôpitaux of Paris on Feb 14th Dr Pierre Marie pointed out that th symptoms of syphilitic spasmodic paraplegia are characteristic—a fact which despite the numerous works on th affection particularly that of Erb has not been sufficiently brought into prominence (*mis en relief*) Though the gait is spastic it is not only spasm which prevents the patients from walking, but also paralysis of the flexors of the lower limbs This paralysis is remarkably localised, the power of the psoas and iliacus muscles is always diminished in a more or less marked *fashion flexion of the thigh on the pelvis* is performed with great difficulty, or at least with considerably less force than in a normal individual. Similarly, there is feebleness of flexion of the knee and of dorsal flexion of the foot but this is generally much less than that of the psoas muscle There is a curious difficulty of adduction of the thighs If the patients are told to press the knees together the latter can almost without effort usually be separated by the hand to a distance of seven or eight centimetres, but no further in consequence of the muscular resistance of the patient. Thus adduction is enfeebled only when the knees are close together. Adopting the suggestion of his pupil, M. Goulden, Dr. Marie thinks that this phenomenon is due to paralysis of the pectineus muscle. The sphincter troubles are also peculiar. There is not incontinence in the ordinary sense, but an imperious desire to micturate and to defecate which must be satisfied at once. Sensory affections are rare. Genital troubles, on the contrary, are common; both sexual desire and power are affected and the cremasteric reflex is often abolished. All the patients', symptoms are not necessarily paraplegic. There may be paræsthesia or weakness of the muscles of the upper limbs, more often of one upper limb. Frequently there is increased susceptibility to emotion—a spasmodic tendency to laugh or to cry; more rarely there is slight loss of memory. Dr. Marie insists that the symptoms on which stress has been laid are so constant that they constitute a well-marked type. The morbid anatomy of the affection he is unable to define. This lucid description well illustrates Dr. Marie's clinical acumen—his power of discovering types where others only observe cases. But while freely admitting the great value of his latest contribution to clinical medicine we venture to think that his description applies to a particular type of syphilitic spasmodic paraplegia rather than to the affection in general.

## ANNAMESE MEDICINE.

"BETTER fifty years of Europe than a cycle of Cathay," sang Lord Tennyson, and in so far as regards Annamese medical practice the late Laureate's dictum would seem to be fully justified. According to a writer in the *Archives de Médecine Navale* for January no native of Annam is allowed to practise medicine or surgery unless he has studied under a recognised master for at least 10 years, but notwithstanding this prolonged curriculum the results, measured by Western standards, are simply deplorable. It is not that the Mongoloid medical students are accused of abnormal idleness or of excessive stupidity, for, on the contrary, they are said to be very industrious and, according to their lights, by no means devoid of intelligence. From their earliest days, however, they become imbued with the grossest superstition, complicated by a firm belief in astrology, and naturally it is next to impossible for genuine knowledge to attain to any useful dimensions in the midst of such exuberant weeds. The Annamese Pharmacopœia is made up of an immense number of exceedingly complex formulæ, and before the simplest of the medicaments can be prepared the compounder has to perform the most perplexing ceremonies in order to insure its efficacy. Amongst metals gold, silver, and iron are in high repute as remedies, but the writer does not make the mode of their administration clear. Iron, he tells us, is used for wounds caused by cutting instruments. In the same connexion it may also be noted that zinc is employed for combating colic as well as for assisting parturition. In the latter case, however, the attendant nails the metal to the threshold of the patient's room. Earth is freely administered in many diseases. When freshly stirred up by rats it is believed to cure paralysis, cramps, and beri-beri, and it is likewise thought capable of preventing the crying of infants in utero. As a comestible earth is freely consumed by well-to-do people throughout the country, but its votaries acknowledge that it has no taste or nourishing properties whatever. Habit, they say, is responsible for the practice, but pregnant women have been known to declare that the "little cats'-ear tiles," as the earth tablets are called, have as good a flavour as pig's liver. The Annamese do not hesitate to consume the flesh of cattle that have died from infectious diseases, and also freely eat fowls that have died from cholera or diphtheria. One of their most cherished drugs consists of small-pox crusts which are given internally as a prophylactic when the disease is exceptionally prevalent. Hydrophobia in Annamese estimation can be communicated to a human being if a mad dog should bite his shadow, but happily the liver of the animal is a sovereign cure! The "stercoraceous" remedies used by the Annamese are more repulsive, if possible, than those of the Honourable Robert Boyle, to which we recently alluded[1]; but, on the other hand, it is pleasant to find that strawberries fortify the five organs of the circulation, cure consumption, and restore youth to old people.

## PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

FOR the purpose of placing a memorial brass in the church of the Royal Victoria Hospital at Netley to the memory of the late Surgeon-General W. Nash, A.M.S., a committee has been formed consisting of Deputy Surgeon-General J. Meane, A.M.D. (ret.), Colonel W. F.-Stevenson, C.B., R.A.M.C., and Colonel W. L. Gubbins, R.A.M.C. It is also proposed to place a portrait of the deceased officer in the headquarters mess of the Royal Army Medical Corps. Subscriptions, which are invited from members of the Army Medical Service and the Royal Army Medical Corps both on the active and retired lists, should be remitted by cheque to 28, Charles-street, St. James's-square, S.W., payable to Major B. M. Skinner, R.A.M.C., and crossed "Sir C. R. McGrigor and Co., Memorial to Surgeon-General Nash." The following subscriptions have already been received: Surgeon-General W. Taylor (Director-General of the Army Medical Service), £2 2*s.*; Surgeon-General A. H. Keogh (Deputy Director-General of the Army Medical Service), £1 10*s.*; and Deputy Surgeon-General J. Meane, £2 2*s.*

## THE CASE OF THE MILE END INFIRMARY.

CERTAIN letters have recently appeared in the *Times* in which Dr. J. Harley Brooks, medical superintendent of the Mile End Infirmary, has explained the circumstances in which seven nurses at that institution declined revaccination and became infected with small-pox introduced into the hospital by a patient in whom its presence was not recognised. In reply to these Mr. Bernard Shaw, the well-known author, who appears to take a praiseworthy interest in the sanitation and health of the metropolitan borough in which he lives and of the community in general, has written criticising the statements and deductions of Dr. Harley Brooks. In a letter which appeared on March 1st Mr. Shaw, who is nothing if not original, propounded the suggestion that "the presence in the Mile End Infirmary of a number of nurses suffering from variolous eruptions on the arm produced not only the outbreak of small-pox among the unrevaccinated nurses but also among the patients." To this Dr. Harley Brooks has replied by pointing out among other things that the revaccination of the nurses who escaped small-pox took place at the end of October and at the beginning of November in last year, while the outbreak of small-pox (apart from its being directly traceable to a patient who died from it) occurred in the following January. Mr. Bernard Shaw does not seem to have very carefully ascertained his facts before propounding deductions to be founded on them. Nor does he explain how if his theory were to be upheld, small-pox would ever be absent from the community. Vaccinated infants suffering from what Mr. Bernard Shaw calls variolous eruptions are not infrequently found in crowded rooms where other persons, vaccinated and unvaccinated, would be far more exposed to the infection of vaccination if it existed than the nurses were at the Mile

---

[1] THE LANCET, Feb. 22nd, 1902, p. 566.

Hunterian Oration of 1877, and the Bradshaw Lecture of 1882, which are familiar to a good many who were present at their delivery or who have seen reprints of them; but Sir James Paget is an author who will bear much re reading. There is no doubt that the book will be a memorial not only of a great but of a lovable man, such as all who knew him either personally or by repute will be glad to possess. In an early issue we hope to give an extended *review of the work.*

## THE PREVALENCE OF SMALL-POX.

THE returns of small-pox in London for the past week are as follows: on Saturday and Sunday, March 8th and 9th, 57 fresh cases in all were notified and removed; on Monday, the 10th, there were 67 fresh cases; on Tuesday, the 11th, there were 76 fresh cases; and on Wednesday, the 12th, there were 52 fresh cases. In Glasgow 11 new cases of small-pox were admitted to the hospital at Belvidere on March 9th and 9 on the 10th. On the same dates 26 patients were dismissed, leaving a total of 202 cases still under treatment.

## THE TREATMENT OF CUTANEOUS EPITHELIOMA BY THE X RAYS.

DR CHARLES WARRENNE ALLEN, Professor of Dermatology in the New York Post-Graduate Medical School, writing in the *New York Medical Record* of Jan. 25th, expresses the opinion that the x rays will eventually be made serviceable in the treatment of cutaneous epithelioma, but at the same time he admits that the method is as yet only in its infancy At present he considers that the proper place of the rays is in the after-treatment or as a means of checking extension of the disease. In dealing with epithelioma he therefore prefers in the first place to follow the ordinary rules of surgical practice, and after an operation has been performed either with the knife or with caustic he strongly recommends that the rays should be applied, not however, to the extent of producing a so called "burn." For the application of the rays, especially to the mouth, throat, uterus, and rectum, he has suggested a funnel-shaped metallic cone, into the flare of which the x-ray tube is inserted. As a source of electrical energy a static machine is preferable for use in an institution or a consulting-room, but in a patient's house an induction coil is obviously more convenient, although, perhaps, inferior from a therapeutic point of view. As to the dangers to be apprehended from the application of the x rays, he believes them to have been over estimated although it is unquestionable that in incompetent hands much damage may be done by this method of treatment, and quacks may be the means of bringing it into some degree of disrepute. He dismisses as mistaken the idea that applications of methylene blue used concurrently with x-ray treatment interfere with the action of the latter.

## THE SALARIES OF ASSISTANT MEDICAL OFFICERS OF THE METROPOLITAN ASYLUMS BOARD.

AT a meeting of *the Metropolitan Asylums Board held on* March 8th the Hospitals Committee sent in a report on the matter of the salaries paid to assistant medical officers. The present scale of pay was adopted some eight years ago and the committee considered that the time had arrived for revision. All assistant medical officers started at a salary of £160 per annum, increasing by annual rises of £20 per annum to £200, together with board, washing, and attendance. The committee now recommended that the salaries should be raised owing to the increase in the cost of medical education and other reasons. The senior assistant medical officer should be paid at a higher rate than the junior. Their recommendations, which were unanimously adopted, may be summarised as follows 1. Senior assistant medical officers to be paid at the rate of £280 per annum for the first year and at the rate of £300 per annum for the second and subsequent years, with board, lodging, washing, and attendance. 2 In future all junior assistant medical officers shall be appointed on probation for not more than six months, such appointment to be subject to confirmation or revocation *by the Hospitals Committee. Salary during this period to be* at the rate of £180 per annum, with board, lodging, washing, and attendance. If the appointment be confirmed the salary is to be at the rate of £180 per annum, commencing from the beginning of probation and to rise by £20 per annum or at longer intervals to £240 per annum, with board, lodging, washing, and attendance. 3. Assistant medical officers already in the service of the Board are to be classified according to length of service and from March 25th, 1902, they shall be paid under the new scale.

## THE DANGERS OF ACETYLENE.

AN important report dealing with the apparatus and material used in the generation of acetylene has recently been printed in a Parliamentary paper. The members of the committee, seven in number, were all experts—some *in regard to explosives, others to petroleum, and others to* coal gas Of the generators examined not one appeared to be unsatisfactory under the conditions of the test, but, as is pointed out, this does not necessarily mean that all the types of generators on the market were safe, for some appliances were withheld because it was felt that they would not pass the test, and in some instances serious defects in the design were made good before the generator was submitted to the test. The committee states that attention should be given to the following five points in regard to the construction of the generator: (1) it should be simple in action and design: (2) it should be strongly constructed; (3) it should give a high efficiency *as indicated by the yield of gas per unit of* carbide; (4) the pressure of gas in the generator should always be low; and (5) the residue of lime in the generator should be easily removeable. There is obviously no reference here to the purity of the carbide. This, it seems to us, is an important point, for the ordinary impurities of carbide are compounds which when moistened with water yield two poisonous gases—namely, phosphoretted hydrogen and sulphuretted hydrogen. Moreover, it is possible that the presence of impurities in carbide might render the gases generated from it spontaneously inflammable.

## THE SYMPTOMATOLOGY OF SYPHILITIC SPASMODIC PARAPLEGIA.

AT the meeting of the Société Médicale des Hôpitaux of Paris on Feb 14th Dr. Pierre Marie pointed out that the symptoms of syphilitic spasmodic paraplegia are characteristic—a fact which, despite the numerous works on the affection, particularly that of Erb, has not been sufficiently brought into prominence (*mis en relief*). Though the gait is spastic, it is not only spasm which prevents the patients *from walking*, but also paralysis of the flexors of the lower limbs This paralysis is remarkably localised; the power of the psoas and iliacus muscles is always diminished in a more or less marked fashion: flexion of the thigh on the pelvis is performed with great difficulty, or at least with considerably less force than in a normal individual. Similarly, there is feebleness of flexion of the knee and of dorsal flexion of the foot, but this is generally much less than that of the psoas muscle There is a curious difficulty of adduction of the thighs: if the patients are told to press the knees together the latter can, almost without effort, usually be separated by the hand to a distance of seven or eight centimetres, but no farther in consequence of the despatch of the relief ship, besides subscribing to the fund. It would be a deplorable thing if from want of funds proper precautions for the safety of the explorers were not taken and a second Franklin disaster should occur. To medical men the undertaking will specially appeal, for more than one member of our profession has taken part—notably John Rae, to mention one name only—in Polar research; but the expedition is really a national one, as its funds were raised by public subscription, supplemented by a Government grant. Moreover, valuable work has already been performed by Captain Scott and his party, and there is every reason to hope that the expedition will be successful if it is properly supported. We sincerely trust that for our own national honour, as well as for the sake of the brave men who volunteered for service in the expedition, the money required will at once be forthcoming.

THE committee appointed by the Lord President of the Council to inquire into the Pharmacy Act, 1868, has been sitting at Whitehall this week under the chairmanship of Sir Herbert Maxwell. The special object of the committee is to decide upon the modifications necessary in the list of poisons referred to in Schedule A of the Act.

Dr. Louis Cobbett and Dr. E. S. St. Barbe Sladen have been appointed by the Royal Commission on Tuberculosis to assist in the experimental work of the Commission to be carried out at Stansted. They will reside at the farms and will devote the whole of their time to the investigations of the Commission.

THE Midwives Bill, as will be seen by our report of the proceedings on page 784, is now being fought out in Committee. An important amendment, moved by Sir John Tuke, to the effect that only certified midwives should be able to sue for fees was carried by 21 votes to 10.

MR. WALTER OTTO GOLDSCHMIDT has presented a cast of the bust of his late mother to the Jenny Lind Infirmary at Norwich. The bust was executed by the late Mr. Joseph Durham, A.R.A., in 1848. It was the only one for which the famous singer ever sat.

THE death is announced at Redhill, on March 7th, of the Rev. William de Lancy West, D.D. He was educated at St. John's College, Oxford, and from 1870 to 1885 was head-master of Epsom College.

HIS MAJESTY THE KING has promised his patronage and that of the Queen to the grand bazaar which is to be held at the French Embassy on June 10th and 11th next for the benefit of the French charities in London.

---

THE ROYAL INSTITUTION.—In a lecture on Some Developments of Electricity delivered on March 8th Lord Rayleigh showed the well-known phenomenon of the luminosity of a fluorescent screen exposed to the Roentgen rays. He then discussed at some length the remarkable effect of these rays in promoting the condensation of aqueous vapour. It has long been known, he said, that if damp air be suddenly expanded—as, for instance, by sucking air from a flask with the mouth—fog is formed in the air thus expanded. The explanation is that the air becomes cooled by the expansion and water vapour becomes condensed. Aitken discovered some years ago that the presence of nuclei of some kind, such as suspended atmospheric motes or dust, was essential to the formation of fog. In course of time the fog disappears by subsidence of the motes which are thus got rid of and the expansion may be repeated without the production of fog. Exposure to the Roentgen radiation greatly heightens the effect. The probable explanation is that this radiation causes the formation of nuclei in large numbers, these nuclei not being motes but molecules of the nature of the ions which are assumed to be formed in the transmission of electricity through solutions capable of electrolysis.

# Looking Back.

FROM

## THE LANCET, *SUNDAY, MARCH* 14, 1824.

*To the Editor of The Lancet.*

SIR,—As I feel not the slightest hesitation to believe that the publication of THE LANCET was intended for the advancement of the Surgical art, as well as for the improvement of medical science in general, so also am I of opinion that the result will realize every expectation which has been entertained of its utility. The very accurate detail of the lectures alone, cannot fail to impress the juvenile reader with an increased degree of understanding of the subjects of which they treat, and will enable him to exercise his talents with the best effects to his future reputation, as well as to society at large.—It has ever been a subject of remark and regret, that Lectures are generally given with a rapidity too great to permit the audience to give them the perfect attention they require to receive from them the information they were intended to convey. These objections are now removed, and the consequences will be important as well as permanent. In reading with attention the Hunterian Oration, which was published in THE LANCET a little time since, I had an opportunity of attentively considering the contents, and through the medium of your paper of this week, I beg leave to say, that although the gratification I enjoyed in hearing the oration delivered by Mr. CLINE, (whom I have ever held in high estimation) exceeded beyond any comparison the pleasure I felt in hearing that delivered by Sir EVERARD HOME in 1822, yet as some observations and statements which fell from the learned orator, were I think rather objectionable, and such as I have no hesitation to believe, would have been so considered by the excellent and meritorious subject of the oration, whom I had the felicity personally to know, I trust I shall be pardoned in taking the liberty to declare them. I profess myself to entertain an opinion somewhat different from many others upon the existence and nature of what is termed genius, and am inclined to impute much more of the discoveries which he made, and the knowledge which he acquired to the enthusiastic ardour (the language of the elegant orator) with which he prosecuted his investigations, than to any independent act of genius alone. Indeed, if we advert to the statement of the worthy President, we shall find that for the first twenty years of Mr. Hunter's life, no particular disposition was discovered denoting a preference for medical subjects, and that it was not till after twenty-seven years of additional application and study that he felt himself qualified to begin his course of lectures, a period which I shall be justified in declaring, is quite sufficient, connected with assiduity like his, to attain a knowledge of any subject, in a very superior degree. If genius were indispensably necessary to the attaining of an art evidently intended for the possession of many, deplorable would be the state of those, who are now sufficiently suffering from the combined influence of inattention and ignorance, and it would also reflect, in a measure, on Providence itself for withholding, from us, generally speaking, those abilities and powers without the possession of which, the practice of the art of surgery cannot be successfully carried on. I by no means intend to deny that genius has often existed, but it was under circumstances very different from the present; for as it is clear that the productions of the earth, matured as they were intended to be, by the industry and labour of man, are given him to relieve his wants and support his personal existence, so the arts and sciences were equally designed to be the food and support of his mental faculties; and as it has but too frequently occurred that the indolence of his disposition, and ingratitude of his nature have prevented him from cultivating them, to the extent they are entitled to, in order to prevent them from falling into a state of total oblivion, (which in justice to futurity cannot be permitted to take place), Providence has been repeatedly called upon to raise up characters possessing more than common propensities to cultivate and perfect any particular art or science, and this is what might properly be deemed genius, conspicuous in its commencement, vigorous in its growth, and expanding to an

End Infirmary, while maternity hospitals would become centres for the dissemination of the disease. In short, Mr. Bernard Shaw can hardly be congratulated upon initiating a discovery likely to bear serious results, while the case of the nurses at Mile End is an excellent example of the protective power of revaccination.

## DINNER OF THE MEDICAL SOCIETY OF LONDON.

THE 129th anniversary dinner of the Medical Society of London was held on March 8th at the Whitehall Rooms, Dr. W. H. Allchin, the President, being in the chair. The guests of the society were Sir William S. Church, Bart. (President of the Royal College of Physicians of London), Mr. H. G. Howse (President of the Royal College of Surgeons of England), Dr. T. Clifford Allbutt (Regius Professor of Physic at the University of Cambridge), Surgeon-General W. Taylor (Director-General of the Army Medical Service), Mr. Alfred Willett (President of the Royal Medical and Chirurgical Society), Mr. Howard Marsh (President of the Clinical Society of London), Mr. Herbert W. Page (President of the Neurological Society), Dr. P. Horrocks (President of the Obstetrical Society of London), Dr. Urban Pritchard (President of the Otological Society of the United Kingdom), Dr. T. E. Burton Brown (Master of the Society of Apothecaries of London), and Dr. Patrick Manson, C.M.G. After the toasts of "The King" and of "The Medical Society of London" the President presented the Fothergillian gold medal to Dr. Manson in recognition of his work on tropical diseases. Dr. Manson replied. Mr. A. Pearce Gould then proposed "Our Fellow Societies," to which Mr. Willett replied. Mr. Edmund Owen proposed the health of "Our Visitors," which was responded to by Sir William Church. Dr. Frederick T. Roberts proposed "The Health of the President," who replied. This terminated a most successful dinner, at which over 100 Fellows of the society and their guests were present.

## "INTERNAL DERANGEMENT" OF THE KNEE-JOINT.

THE cases designated by the above title are of particular importance because they most commonly occur in active youthful or middle-aged subjects, and thus the condition disables a person in other respects especially able so far as his physical powers are concerned. With modern surgery a great advance has been made in the treatment of these cases, the classical description of which was given in a paper by Hey. This surgeon, however, appears to have considered the symptoms which he so well described to be always due to dislocation of a semilunar cartilage. That this is by no means always the case we are now certain and the variety of lesion which may cause frequent attacks of inability to extend the knee and of pain and weakness in the joint is well shown in the paper which we publish by Mr. Herbert Allingham at p. 731 of our present issue Mr. Allingham certainly includes some conditions which have not hitherto often been recognised as giving rise to the same symptoms as those occasioned by injury to the semilunar cartilages, but he also shows the different conditions in the cartilages themselves which cause Hey's symptoms of "dislocation." His series of cases is very instructive from this point of view and the loose bodies and various splittings and separations from attachments which his cases illustrate were paralleled by the examples recently given in our columns by Mr A. E. Barker[1] and Mr. J. M. Cotterill.[2] It is interesting to note that Mr. Barker does not seem to consider splitting of a semilunar cartilage across at any point between its two ends at all probable on scientific grounds and he had not met with such a condition. His paper, however, did not put forward a large number of cases, and Mr. Allingham's wider series includes examples apparently of this lesion which Mr. Cotterill also states that he has found. An instructive feature is the case with which displacement of a semilunar cartilage appears to occur in certain subjects, particularly those who for any reason have suffered from chronic synovitis of a knee-joint. As regards treatment Mr. Allingham lays especial stress on the value of massage and exercises, and there is no doubt that the condition of the ligaments and muscles accessory to the joint plays an important part in the prevention of the attacks caused by internal derangement. Cases in which there are frequent recurrences, however, and those where there is a perfectly free piece of cartilage, are not satisfactorily treated without operation

## HUNTER AND URINARY SURGERY.

IN his recent Hunterian Lecture before the Hunterian Society Mr. Reginald Harrison claimed that in many points the teaching of John Hunter might be said to represent even the most advanced teaching of the present day. Urinary fistulæ in the perineum are often exceedingly troublesome, for they may refuse to heal in spite of much energetic treatment. Hunter showed by the analogy of a lithotomy wound that the non-healing was not due merely to the fact that urine was passing over the wound. There must therefore be some other cause for the lack of healing. The essential provision for the closing of these urinary fistulæ is a perfectly free channel for the escape of the urine, and, as Mr. Harrison pointed out, it may be even at the present time the best treatment to perform a perineal section to allow the urine to escape freely, and he quoted a case in which five urinary fistulæ were in this manner induced to close, although for 18 months previously many other forms of treatment had been employed in vain. Again, with regard to vesical hæmorrhage, Hunter advised perineal section for cases in which profuse hæmorrhage occurred into the bladder with the formation of large clots. In this way the bladder is thoroughly rested and the clots are easily removed. Mr. Harrison cited many other instances of the value of Hunter's practice and suggestions in this department of surgery; many of them are of great interest, but all who have studied Hunter's work will know that it was founded on a firm basis of pathology; and though as our knowledge surpasses that which he possessed we can accomplish more than was possible to him, yet much that he taught will be of value as long as surgery shall endure

## THE NATIONAL ANTARCTIC EXPEDITION RELIEF FUND.

IT is not at all creditable to the people of a country which has produced so many daring sailors and whose history is so closely associated with maritime adventure that any very great efforts should be required to find the money necessary to equip a relief ship in order to render assistance to Captain Scott who left London on July 31st last on a voyage of antarctic research. Captain Scott of the *Discovery* in a letter to Sir Clements R. Markham, President of the Royal Geographical Society, dated Lyttelton, Dec. 17th, 1901, expresses his confidence that a relief ship will be sent to him, but only a little more than £8000, including a magnificent subscription of £5000 from Mr. L. W. Longstaff, have been as yet subscribed towards this object, or less than half the £20,000 required for the purpose of equipping the relief vessel. His Majesty the King is patron of the expedition, and H. R. H. the Prince of Wales, the vice-patron, has expressed himself very strongly as to the urgent necessity for the

[1] THE LANCET, Jan 4th, 1902, p. 7.
[2] THE LANCET, Feb. 22nd, 1902, p. 510.

Thames was in flood. At length we are glad to see that this for once has been done. During the month of December two analyses were made of the water supplied by the Grand Junction Company. The results are given in the following table :—

TABLE III.—*Giving the Results of the Analyses, expressed in parts per 100,000, of Two Specimens of the Water supplied by the Grand Junction Waterworks Company in December, 1901. (From the report of analyses of the metropolitan water-supply undertaken by Dr. T. E. Thorpe, F.R.S., on behalf of the Local Government Board.)*

| Date. | Place of collection. | Organic carbon. | Organic nitrogen. | Ammonia. | Chlorine. |
|---|---|---|---|---|---|
| Dec. 9th, 1901. | Cab rank, Piccadilly, opposite Bolton-street ... ... ... | 0 129 | 0 014 | 0 0 | 1·9 |
| ,, 31st,* ,, | Cab rank, Shepherd's Bush Green . ... | 0 287 | 0 032 | 0 014 | 2 2 |

* The Thames water was in a "bad" state from and including Dec. 26th to the end of the month.

In his remarks on the results of the analyses Dr. Thorpe says: "The Grand Junction Company's supply on Dec. 31st, ...... contained a considerable proportion of organic impurity, chiefly of vegetable origin. ......" Dr. Thorpe also makes some remarks on the presence of ammonia, which he found in comparatively large quantity in the water supplied on Dec. 30th and 31st: "The supply of these companies" (the Southwark, Grand Junction, and Lambeth), he says, "on several occasions in the latter part of the month contained sensible amounts of free ammonia, the largest proportion (0 023 part per 1000) being found in the Grand Junction Company's water on Dec. 30th. As free ammonia in more than minute traces is only exceptionally found in the filtered waters, it appears that this constituent must have been present in more than usual proportion in the raw Thames water during the recent floods." This hypothesis is, perhaps, not of much importance The fact on which we would insist is that ammonia should not be distributed in the drinking-water supplied to the people of London. Enough has been said to prove that the water supplied by the Grand Junction company gives conclusive evidence to show that the method in which it is treated is defective.

Is the President of the Local Government Board aware that the capacity of the storage and subsidence reservoirs of the Grand Junction Waterworks Company is insufficient in amount?

Is the President of the Local Government Board aware that the quality of the water supplied by the Grand Junction Waterworks Company gives conclusive evidence that the manner in which it is treated is defective?

If the President of the Local Government Board is not aware of these facts, will he make himself acquainted with the reports of the Water Examiner and of the analyst who are appointed by the Local Government Board?

If the President of the Local Government Board is aware of the facts, has he made any communication to the directors of the Grand Junction Waterworks Company with reference to them? If he has not done so, why has he not done so? If he has done so, when did he do so and with what result?

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 9143 births and 5835 deaths were registered during the week ending March 8th. The annual rate of mortality in these towns, which had been 24 4 and 23·3 per 1000 in the two preceding weeks, further declined last week to 20·5 per 1000. In London the death-rate was 24·6 per 1000, while it averaged 18·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 10·1 in Smethwick, 11·0 in Hornsey, 11·4 in Wolverhampton, 12·4 in Walthamstow, 12·8 in Middlesbrough, 13·1 in Great Yarmouth, and 13·7 in Plymouth and in Swansea; the highest rates were 25·2 in Preston and in Huddersfield, 25·5 in Warrington, 26·0 in Bury, 27·0 in Burnley, 27·4 in Blackburn, 27·6 in Stockport, and 30·4 in Barrow-in-Furness. The 5835 deaths in these towns last week included 600 which were referred to the principal zymotic diseases, against 582 and 570 in the two preceding weeks; of these 600 deaths 167 resulted from measles, 120 from whooping-cough, 92 from small-pox, 89 from diphtheria, 52 from scarlet fever, 42 from "fever," and 38 from diarrhœa. No death from any of these diseases occurred last week in Hastings, Bournemouth, Great Yarmouth, Hanley, Burton-on-Trent, Kings Norton, Smethwick, or Tynemouth; in the other towns they caused the highest death-rates in Willesden, Tottenham, Northampton, Leicester, Bootle, Wigan, Burnley, and Blackburn. The greatest proportional mortality from measles occurred in Tottenham, Willesden, Southampton, Northampton, Leicester, Stockport, Burnley, and Huddersfield; from scarlet fever in Wigan and in Handsworth; from diphtheria in Portsmouth, Bristol, and Derby; from whooping-cough in Devonport, Walsall, and Leicester, from "fever" in St. Helens and in Bolton; and from diarrhœa in Bootle. 92 fatal cases of small-pox among persons belonging to these 76 towns were registered last week; of these, 80 belonged to London, six to West Ham, and one each to Croydon, Tottenham, East Ham, Reading, Leicester, and Swansea. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1185, 1321, and 1309 on the three preceding Saturdays, had risen to 1512 on Saturday, March 8th; 555 new cases were admitted during the week, against 390, 502, and 379 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2283, against numbers decreasing from 3137 to 2307 on the 10 preceding Saturdays; 277 new cases were admitted during the week, against 260, 219, and 215 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 885 and 733 in the two preceding weeks, further declined last week to 590, but were 53 above the corrected average. The deaths directly attributed to influenza numbered 89, having been 51. 107, and 103 in the three preceding weeks. The causes of 76, or 1·5 per cent., of the deaths in the 76 large towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Salford, Leeds, Newcastle, and in 41 other smaller towns; the largest proportions of uncertified deaths were registered in Reading, St. Helens, Warrington, Preston, Sheffield, and South Shields.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 25·3 and 22·6 per 1000 in the two preceding weeks, rose again to 25 4 per 1000 during the week ending March 8th and exceeded by 4·9 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15 6 in Perth and 19 2 in Paisley to 26 9 in Edinburgh and 29 8 in Dundee. The 820 deaths in these towns included 20 which were referred to whooping-cough, 17 to diarrhœa, 14 to measles, seven to scarlet fever, seven to diphtheria, two to small-pox, and two to "fever." In all 69 deaths resulted from these principal zymotic diseases last week, against 81 and 75 in the two preceding weeks. These 69 deaths were equal to a annual rate of 2·1 per 1000, which corresponded wit the mean rate last week from the same diseases i the 76 large English towns. The fatal cases of whooping-cough, which had been 20, 20, and 23 in the three precedin weeks, declined again last week to 20, of which eight occurre in Glasgow, five in Aberdeen, three in Edinburgh, and tw in Dundee The deaths from diarrhœa, which had been and 13 in the two preceding weeks, rose again to 17 last wee and included nine in Glasgow and five in Edinburgh. T fatal cases of measles, which had been 12, 17, and 19 in t three preceding weeks, declined again last week to 14, which nine were registered in Glasgow and three in Dund The deaths from scarlet fever, which had been three a four in the two preceding weeks, further rose to seven last week and included four in Glasgow. The fatal cases of diphtheria, which had been three, six, and one in the three preceding weeks, rose again last week to seven, of which two occurred in Dundee and two in Greenock The deaths from small-pox, which had been two, seven, and extent which throws at a distance all impediments arising from the imperfections of our nature Another objection, which I feel to enthusiasm, such as was possessed by the individual so justly and universally admired, being imputed to genius alone is, that independently of the derivation from his energy and zeal, he is held up to posterity more as a subject of admiration for his genius (if such it must be *deemed*) *than imitable for his talents, industry, and knowledge*, and thus rendered at one moment elevated, but useless, a point of view, in which to have been considered by after ages, that would have rendered him truly miserable Inquiries into the arcana, the principles and perfections of nature, aided by investigation so accurate as was his will ever from nature receive information and instruction and among many other advantages, which would certainly accrue, a release from the prevailing influence of the liver humbuggery would be one inevitable and invaluable result the liver being an organ more connected with, than productive of, the diseases of the digestive organ more sinned against than sinning, the means employed for the removal of which have been productive of distress disease, and destruction to thousands It is a well known fact that many of the islands in the intertropical seas are formed by the association and combination of animalculæ of the Polypi description, thus interminably forming a perfect separation between land and water Surely therefore the combination of human talent if energetically exerted can separate knowledge from ignorance and science from quackery

I am, Sir,
Your obedient servant,
GEORGE WILKINS,
Surgeon

36, York place City road,
March 10 1824

# THE METROPOLITAN WATER SUPPLY

## III [1]

### THE GRAND JUNCTION WATERWORKS COMPANY SOME QUESTIONS FOR THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD

THE arrangements of the Grand Junction Waterworks Company are in one respect more unsatisfactory than are those of any of the other metropolitan water companies

1 There is a great deficiency in reservoir capacity

2 The water supplied by the company gives evidence of the defective method in which it is treated

1 The marked deficiency in the capacity of the storage reservoirs of the Grand Junction Company is very clearly seen by comparing it with that of the West Middlesex Company and for this purpose a table has been compiled from the monthly report of the Water Examiner for December 1901 The West Middlesex company is taken for purposes of comparison for reasons which were given in the second of these articles [2] which were, briefly stated that the arrangements of the company were put into a moderately efficient state by the directors as soon as the shareholders of the company had received their back dividends and their future full statutory dividends appeared to be secure Table I shows the daily average amount of water supplied by the West Middlesex and the Grand Junction companies for the month of December 1901 (the latest available statistics) It gives also the estimated population supplied the area and capacity of the storage and subsidence reservoirs of the two companies and the area of their filter beds

This table speaks for itself Whoever has eyes to see can see if he chooses to look The West Middlesex Company which was distributing something less than 21 000 000 gallons of water, has a storage area of 117 acres and the Grand Junction Company, with a storage area of only 15 acres was distributing nearly 19 000 000 gallons daily The storage capacity of the Grand Junction Company would have to be increased more than sixfold to equal that of the West Middlesex Company No amount of expert evidence can alter this fact No truthful man could deny that the reservoir capacity of the Grand Junction Company is extremely inadequate, and as a tree is known by its fruit so the imperfections in the arrangements of a water company are shown by the quality of the water which it supplies

TABLE I.—*Showing the Daily Average Amount of Water Supplied and the Estimated Population Served during the Month of December 1901, and the Area and Capacity of the Storage and Subsidence Reservoirs and the Filtration Areas of the West Middlesex Waterworks Company and the Grand Junction Waterworks Company* (*Compiled from the report of the Water Examiner*)

| Companies | Average daily supply during the month | Estimated population | Storage and subsidence reservoirs | | Filtration area in acres |
|---|---|---|---|---|---|
| | | | Area in acres | Capacity in gallons | |
| West Middlesex Waterworks Company | 20 565 429 | 650 734 | 117½ | 397 500 000 | 22½ |
| Grand Junction Waterworks Company | 18 917 127 | 449 764 | 15 | 53 570 000 | 24½ |

2 In the last published annual report of the Local Government Board [3] Dr T E Thorpe, F R S, the analyst appointed by the Board called the attention of the President to the great importance which should be attached to the adequacy of the capacity of subsidence reservoirs and to the effects which were produced by a deficiency in this respect He pointed out that by drawing on their stored water at periods during which the Thames is in a dirty state some companies distribute their supplies in a less impure condition than they would have been able to do had they possessed no arrangements for storage An instructive table was given to elucidate this point and to show the relative positions of the Thames companies with regard to storage and to the organic elements in the water which they delivered during the six winter months of 1900 The table is as follows —

TABLE II.—*Showing the Relative Positions of the Thames Companies with regard to Storage and to the Organic Elements in the Water which they delivered during the Six Winter Months of 1900*

| Companies | Number of days supply in unfiltered water reservoirs | Organic elements (carbon and nitrogen) average for months of January February, March October November and December in parts per 100 000 |
|---|---|---|
| Chelsea | 15·0 | 0·203 |
| West Middlesex | 18·5 | 0·219 |
| Southwark | 13·2 | 0·303 |
| Grand Junction | 2·9 | 0·342 |
| Lambeth | 6·0 | 0·327 |

In his comments on this table Dr Thorpe says "From this it is seen that the Chelsea West Middlesex, and Southwark companies having from 13·2 to 18·5 days storage, delivered the best water The Grand Junction with less than three days storage delivered water containing the most organic matter whilst the Lambeth Company with but little more storage succeeded in supplying slightly better [we should prefer to say *less impure*] water than the former company

We have had occasion to call attention to the fact that the analyst of the Local Government Board has not been allowed or instructed to make a sufficient number of observations on the quality of the water supplied by the metropolitan water companies For a long time only one full analysis was made monthly of one specimen only of the water supplied by each company There has been no evidence to show that the specimen has not been taken in a perfectly haphazard manner in regard to the time at which it was taken We have insisted that it was necessary that analyses should be made at times during which the

[3] Thirtieth Annual Report of the Local Government Board, 1900-1901, London 1901

Thames was in flood. At length we are glad to see that this for once has been done. During the month of December two analyses were made of the water supplied by the Grand Junction Company. The results are given in the following table:—

TABLE III.—*Giving the Results of the Analyses, expressed in parts per 100,000, of Two Specimens of the Water supplied by the Grand Junction Waterworks Company in December, 1901. (From the report of analyses of the metropolitan water-supply undertaken by Dr. T. E. Thorpe, F.R.S., on behalf of the Local Government Board.)*

| Date. | Place of collection. | Organic carbon. | Organic nitrogen. | Ammonia. | Chlorine. |
|---|---|---|---|---|---|
| Dec. 9th, 1901. | Cab rank, Piccadilly, opposite Bolton-street ... ... ... | 0·129 | 0·014 | 0·0 | 1·9 |
| „ 31st;* „ | Cab rank, Shepherd's Bush Green ... ... | 0·287 | 0·032 | 0·014 | 2·2 |

* The Thames water was in a "bad" state from and including Dec. 26th to the end of the month.

In his remarks on the results of the analyses Dr. Thorpe says: "The Grand Junction Company's supply on Dec. 31st, ...... contained a considerable proportion of organic impurity, chiefly of vegetable origin. ......" Dr. Thorpe also makes some remarks on the presence of ammonia, which he found in comparatively large quantity in the water supplied on Dec. 30th and 31st: "The supply of these companies" (the Southwark, Grand Junction, and Lambeth), he says, "on several occasions in the latter part of the month contained sensible amounts of free ammonia, the largest proportion (0·023 part per 1000) being found in the Grand Junction Company's water on Dec. 30th. As free ammonia in more than minute traces is only exceptionally found in the filtered waters, it appears that this constituent must have been present in more than usual proportion in the raw Thames water during the recent floods." This hypothesis is, perhaps, not of much importance. The fact on which we would insist is that ammonia should not be distributed in the drinking-water supplied to the people of London. Enough has been said to prove that the water supplied by the Grand Junction company gives conclusive evidence to show that method in which it is treated is defective.

Is the President of the Local Government Board aware that the capacity of the storage and subsidence reservoirs of the Grand Junction Waterworks Company is insufficient in amount?

Is the President of the Local Government Board aware that the quality of the water supplied by the Grand Junction Waterworks Company gives conclusive evidence that the manner in which it is treated is defective?

If the President of the Local Government Board is not aware of these facts, will he make himself acquainted with the reports of the Water Examiner and of the analyst who are appointed by the Local Government Board?

If the President of the Local Government Board is aware of the facts, has he made any communication to the directors of the Grand Junction Waterworks Company with reference to them? If he has not done so, why has he not done so? If he has done so, when did he do so and with what result?

# VITAL STATISTICS.

## HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9143 births and 5835 deaths were registered during the week ending March 8th. The annual rate of mortality in these towns, which had been 24·4 and 23·3 per 1000 in the two preceding weeks, further declined last week to 20·5 per 1000. In London the death-rate was 24·6 per 1000, while it averaged 18·8 per 1000 in the 75 other large towns. The lowest death-rates in these towns were 10·1 in Smethwick, 11·0 in Hornsey, 11·4 in Wolverhampton, 12·4 in Walthamstow, 12·8 in Middlesbrough, 13·1 in Great Yarmouth, and 13·7 in Plymouth and in Swansea; the highest rates were 25·2 in Preston and in Huddersfield, 25·5 in Warrington, 26·0 in Bury, 27·0 in Burnley, 27·4 in Blackburn, 27·6 in Stockport, and 30·4 in Barrow-in-Furness. The 5835 deaths in these towns last week included 600 which were referred to the principal zymotic diseases, against 582 and 570 in the two preceding weeks; of these 600 deaths 167 resulted from measles, 120 from whooping-cough, 92 from small-pox, 89 from diphtheria, 52 from scarlet fever, 42 from "fever," and 38 from diarrhœa. No death from any of these diseases occurred last week in Hastings, Bournemouth, Great Yarmouth, Hanley, Burton-on-Trent, Kings Norton, Smethwick, or Tynemouth; in the other towns they caused the highest death-rates in Willesden, Tottenham, Northampton, Leicester, Bootle, Wigan, Burnley, and Blackburn. The greatest proportional mortality from measles occurred in Tottenham, Willesden, Southampton, Northampton, Leicester, Stockport, Burnley, and Huddersfield; from scarlet fever in Wigan and in Handsworth; from diphtheria in Portsmouth, Bristol, and Derby; from whooping-cough in Devonport, Walsall, and Leicester, from "fever" in St. Helens and in Bolton; and from diarrhœa in Bootle. 92 fatal cases of small-pox among persons belonging to these 76 towns were registered last week; of these, 80 belonged to London, six to West Ham, and one each to Croydon, Tottenham, East Ham, Reading, Leicester, and Swansea. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1185, 1321, and 1309 on the three preceding Saturdays, had risen to 1512 on Saturday, March 8th; 555 new cases were admitted during the week, against 390, 502, and 379 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2283, against numbers decreasing from 3137 to 2307 on the 10 preceding Saturdays; 277 new cases were admitted during the week, against 260, 219, and 215 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 885 and 733 in the two preceding weeks, further declined last week to 590, but were 53 above the corrected average. The deaths directly attributed to influenza numbered 89, having been 51. 107, and 103 in the three preceding weeks. The causes of 76, or 1·5 per cent., of the deaths in the 76 large towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Salford, Leeds, Newcastle, and in 41 other smaller towns; the largest proportions of uncertified deaths were registered in Reading, St. Helens, Warrington, Preston, Sheffield, and South Shields.

## HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 25·3 and 22·6 per 1000 in the two preceding weeks, rose again to 25·4 per 1000 during the week ending March 8th and exceeded by 4·9 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 15·6 in Perth and 19·2 in Paisley to 26·9 in Edinburgh and 29·8 in Dundee. The 820 deaths in these towns included 20 which were referred to whooping-cough, 17 to diarrhœa, 14 to measles, seven to scarlet fever, seven to diphtheria, two to small-pox, and two to "fever." In all 69 deaths resulted from these principal zymotic diseases last week, against 81 and 75 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·1 per 1000, which corresponded with the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 20, 20, and 23 in the three preceding weeks, declined again last week to 20, of which eight occurred in Glasgow, five in Aberdeen, three in Edinburgh, and two in Dundee. The deaths from diarrhœa, which had been 22 and 13 in the two preceding weeks, rose again to 17 last week, and included nine in Glasgow and five in Edinburgh. The fatal cases of measles, which had been 12, 17, and 19 in the three preceding weeks, declined again last week to 14, of which nine were registered in Glasgow and three in Dundee. The deaths from scarlet fever, which had been three and four in the two preceding weeks, further rose to seven last week and included four in Glasgow. The fatal cases of diphtheria, which had been three, six, and one in the three preceding weeks, rose again last week to seven, of which two occurred in Dundee and two in Greenock. The deaths from small-pox, which had been two, seven, and

10 in the three preceding weeks, declined again last week to two, both of which were registered in Glasgow, where the two fatal cases of "fever" also occurred The deaths referred to diseases of the respiratory organs in these towns, which had been 211, 224, and 214 in the three preceding weeks, rose again last week to 230, and were 69 in excess of the number in the corresponding period of last year The causes of 48, or nearly 6 per cent, of the deaths in these eight towns last week were not certified

---

### HEALTH OF DUBLIN

The death rate in Dublin, which had been 33 3 and 28 6 per 1000 in the two preceding weeks, rose again to 29 7 per 1000 during the week ending March 8th During the past four weeks the death rate has averaged 29 3 per 1000, the rates during the same period being 27·0 in London and 23 1 in Edinburgh The 216 deaths of persons belonging to Dublin registered during the week under notice showed an excess of eight over the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against 11, 11, and 13 in the three preceding weeks; of these, six resulted from measles, three from diphtheria, two from "fever," one from scarlet fever, and one from diarrhœa These 13 deaths were equal to an annual rate of 1 8 per 1000, the zymotic death rates during the same period being 2 7 in London and 1 6 in Edinburgh The fatal cases of measles, which had been three, three, and one in the three preceding weeks, rose again last week to six The deaths referred to "fever," which had been three in each of the two preceding weeks, declined last week to two The three fatal cases of scarlet fever exceeded the number recorded in any recent week The 216 deaths in Dublin last week included 32 of children under one year of age and 75 of persons aged upwards of 60 years, the deaths of infants showed a slight decline from the number in the preceding week, while those of elderly persons were considerably in excess Five inquest cases and three deaths from violence were registered, and 81, or three eighths, of the deaths occurred in public institutions The causes of eight, or nearly 4 per cent, of the deaths in Dublin last week were not certified

---

### VITAL STATISTICS OF LONDON DURING FEBRUARY, 1902

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 11 4 per 1000 of the population, estimated at 4,579,107 persons in the middle of the year In the three preceding months the rates *had been 11·6, 10 6 and 11 4 per 1000 respectively* The rates were considerably below the average in Kensington, Fulham, Chelsea, and Hampstead, while they showed the largest excess in Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar During the four weeks ending March 1st the number of small pox cases notified showed a further increase over the numbers in recent months, the greatest proportional prevalence of this disease was recorded in Holborn, Finsbury, Shoreditch Bethnal Green, Stepney, and Poplar The number of small pox patients under treatment in the Metropolitan Asylums hospitals which had been 427 666 and 1135 at the end of the three preceding months had further risen to 1309 at the end of February, the weekly admissions averaged 390, against 110, 173, and 297 in the three preceding months. The prevalence of scarlet fever during February showed a considerable decline from that recorded in the preceding month, among the various metropolitan boroughs this disease was proportionally most prevalent in St Pancras Finsbury Poplar, Battersea Camberwell, and Lewisham The Metropolitan Asylums hospitals contained 2250 scarlet fever patients at the end of the month, against *3186 3080 and 2501 at the end of the* three preceding months, the weekly admissions averaged 234, against 352, 297, and 266 in the three preceding months A continued decline in the prevalence of diphtheria also was shown during February, this disease was proportionally most prevalent in St Pancras, Islington, Stoke Newington, Hackney, Camberwell, and Lewisham There were 1156 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1504, 1369 and 1231 at the end of the three preceding months; the weekly admissions averaged 154, against 200, 160, and 167 in the three preceding months. The prevalence of enteric fever *showed a slight increase* during February, among the various metropolitan boroughs "fever" was proportionally most prevalent in Paddington Hampstead, Holborn, Southwark, and Bermondsey The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 245, 195 and 128 at the end of the three preceding months, had risen again to 143 at the end of February, the weekly admissions averaged 22 against 32, 21 and 18, in the three preceding months Erysipelas was proportionally most prevalent in Hackney, Bethnal Green Southwark, Bermondsey, and Greenwich The 23 cases of puerperal fever notified during the month included five in Wandsworth three in Camberwell, two in Paddington, two in St Pancras, and two in Deptford

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the boroughs in which the deceased persons had previously resided During the four weeks ending March 1st the deaths of 9105 persons belonging to London were registered, equal to an annual rate of 25 9 per 1000, against 20 0, 18 8, and 18 3 per 1000 in the three preceding months The lowest death rates last month in the various metropolitan boroughs were 19 1 in Hampstead, 20 0 in Deptford, 20 4 in Wandsworth, 21 0 in Lewisham and 21 8 in Battersea, the highest rates were 30 3 in St Marylebone, 30 6 in Shoreditch 31 3 in Bethnal Green, 33 6 in Holborn, and 34 6 in Finsbury and in the City of London The 9015 deaths from all causes included 257 from small pox, 229 from measles 49 from scarlet fever, 128 from diphtheria, 154 from whooping cough, 45 from enteric fever, one from simple continued fever, and 34 from diarrhœa, in all 897 deaths were referred to these principal zymotic diseases The lowest death rates last month from these diseases were 1 1 in Battersea and in Camberwell, 1·2 in Chelsea, 1 4 in Bermondsey, and 1 5 in Deptford and in the City of London, and the highest rates were 4 3 in Paddington, 4 6 in Bethnal Green, 4·9 in Finsbury, 5 3 in Stepney, and 7 2 in Shoreditch The 257 fatal cases of small pox showed a further considerable increase over the numbers recorded in recent months, the greatest proportional mortality from this disease occurred in Holborn *Finsbury, Shoreditch, Bethnal Green, Stepney, and* Poplar The 229 deaths from measles were 40 in excess of the average number in the corresponding periods of the 10 preceding years, among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Kensington, Hammersmith, Fulham St Marylebone, and Finsbury The 49 fatal cases of scarlet fever showed a slight decline from the corrected average number; this disease was proportionally most fatal in Hampstead, St Pancras Bethnal Green, Camberwell, Deptford, and Lewisham The 128 deaths from diphtheria were considerably below the average number in the corresponding periods of the 10 preceding years, among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Fulham St Pancras Islington, Finsbury, Shoreditch and Lewisham The 154 fatal cases of whooping cough showed a decline of 78 from the corrected average number, this disease was proportionally most fatal in Stoke Newington, Shoreditch, Bethnal Green Stepney, Lewisham, and Woolwich The 46 deaths referred to "fever" were four in excess of the average number in the corresponding periods of the 10 preceding years, the highest "fever" death rates last month were recorded in the City of Westminster, Hackney, Shoreditch, Bethnal Green and Poplar The 34 fatal cases of diarrhœa were 21 below the corrected average number; this disease was proportionally most fatal in Holborn Shoreditch, Stepney Poplar, and Greenwich In conclusion, it may be stated that the aggregate mortality in London last month from these diseases was nearly 22 per cent. above the average.

Infant mortality in London during February, measured by the proportion of deaths among children under one year of age to registered births was equal to 144 per 1000 The lowest rates of infant mortality were recorded in St Marylebone, Stoke Newington, Hackney, the City of London, Southwark and Deptford, and the highest rates in Chelsea, St Pancras, Finsbury, Poplar, Bermondsey, and Greenwich

* Includin

10 in the three preceding weeks, declined again last week to two, both of which were registered in Glasgow, where the two fatal cases of "fever" also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 211, 224, and 214 in the three preceding weeks, rose again last week to 230, and were 69 in excess of the number in the corresponding period of last year. The causes of 48, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

---

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 33·3 and 28·6 per 1000 in the two preceding weeks, rose again to 29·7 per 1000 during the week ending March 8th. During the past four weeks the death-rate has averaged 29·3 per 1000, the rates during the same period being 27·0 in London and 23·1 in Edinburgh. The 216 deaths of persons belonging to Dublin registered during the week under notice showed an excess of eight over the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against 11, 11, and 13 in the three preceding weeks; of these, six resulted from measles, three from diphtheria, two from "fever," one from scarlet fever, and one from diarrhœa. These 13 deaths were equal to an annual rate of 1·8 per 1000, the zymotic death-rates during the same period being 2·7 in London and 1 6 in Edinburgh. The fatal cases of measles, which had been three, three, and one in the three preceding weeks, rose again last week to six. The deaths referred to "fever," which had been three in each of the two preceding weeks, declined last week to two. The three fatal cases of scarlet fever exceeded the number recorded in any recent week. The 216 deaths in Dublin last week included 32 of children under one year of age and 75 of persons aged upwards of 60 years; the deaths of infants showed a slight decline from the number in the preceding week, while those of elderly persons were considerably in excess. Five inquest cases and three deaths from violence were registered; and 81, or three-eighths, of the deaths occurred in public institutions. The causes of eight, or nearly 4 per cent., of the deaths in Dublin last week were not certified.

---

### VITAL STATISTICS OF LONDON DURING FEBRUARY, 1902.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 11·4 per 1000 of the population, estimated at 4,579,107 persons in the middle of the year. In the three preceding months the rates had been 11·6, 10·6, and 11 4 per 1000 respectively. The rates were considerably below the average in Kensington, Fulham, Chelsea, and Hampstead, while they showed the largest excess in Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. During the four weeks ending March 1st the number of small-pox cases notified showed a further increase over the numbers in recent months; the greatest proportional prevalence of this disease was recorded in Holborn, Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 427, 666, and 1135 at the end of the three preceding months, had further risen to 1309 at the end of February; the weekly admissions averaged 390, against 110, 173, and 297 in the three preceding months. The prevalence of scarlet fever during February showed a considerable decline from that recorded in the preceding month; among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras, Finsbury, Poplar, Battersea, Camberwell, and Lewisham. The Metropolitan Asylums hospitals contained 2250 scarlet fever patients at the end of the month, against 3186, 3080, and 2501 at the end of the three preceding months; the weekly admissions averaged 234, against 352, 297, and 266 in the three preceding months. A continued decline in the prevalence of diphtheria also was shown during February; this disease was proportionally most prevalent in St. Pancras, Islington, Stoke Newington, Hackney, Camberwell, and Lewisham. There were 1156 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1504, 1369, and 1231 at the end of the three preceding months; the weekly admissions averaged 154, against 200, 160, and 167 in the three preceding months. The prevalence of enteric fever showed a slight increase during February; among the various metropolitan boroughs "fever" was proportionally most prevalent in Paddington, Hampstead, Holborn, Southwark, and Bermondsey. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 245, 195, and 128 at the end of the three preceding months, had risen again to 143 at the end of February; the weekly admissions averaged 22, against 32, 21 and 18, in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Bethnal Green, Southwark, Bermondsey, and Greenwich. The 23 cases of puerperal fever notified during the month included five in Wandsworth, three in Camberwell, two in Paddington, two in St. Pancras, and two in Deptford.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occuring in the public institutions of London having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending March 1st the deaths of 9105 persons belonging to London were registered, equal to an annual rate of 25 9 per 1000, against 20·0, 18·8, and 18·3 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 19·1 in Hampstead, 20·0 in Deptford, 20·4 in Wandsworth, 21·0 in Lewisham, and 21 8 in Battersea; the highest rates were 30·3 in St. Marylebone, 30 6 in Shoreditch, 31·3 in Bethnal Green, 33·6 in Holborn, and 34·6 in Finsbury and in the City of London. The 9015 deaths from all causes included 257 from small-pox, 229 from measles, 49 from scarlet fever, 128 from diphtheria, 154 from whooping-cough, 45 from enteric fever, one from simple continued fever, and 34 from diarrhœa; in all, 897 deaths were referred to these principal zymotic diseases. The lowest death-rates last month from these diseases were 1·1 in Battersea and in Camberwell, 1·2 in Chelsea, 1·4 in Bermondsey, and 1·5 in Deptford and in the City of London; and the highest rates were 4 3 in Paddington, 4 6 in Bethnal Green, 4·9 in Finsbury, 5·3 in Stepney, and 7·2 in Shoreditch. The 257 fatal cases of small-pox showed a further considerable increase over the numbers recorded in recent months; the greatest proportional mortality from this disease occurred in Holborn, Finsbury, Shoreditch, Bethnal Green, Stepney, and Poplar. The 229 deaths from measles were 40 in excess of the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Paddington, Kensington, Hammersmith, Fulham, St. Marylebone, and Finsbury. The 49 fatal cases of scarlet fever showed a slight decline from the corrected average number; this disease was proportionally most fatal in Hampstead, St. Pancras, Bethnal Green, Camberwell, Deptford, and Lewisham. The 128 deaths from diphtheria were considerably below the average number in the corresponding periods of the 10 preceding years; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Fulham, St. Pancras, Islington, Finsbury, Shoreditch, and Lewisham. The 154 fatal cases of whooping-cough showed a decline of 78 from the corrected average number; this disease was proportionally most fatal in Stoke Newington, Shoreditch, Bethnal Green, Stepney, Lewisham, and Woolwich. The 46 deaths referred to "fever" were four in excess of the average number in the corresponding periods of the 10 preceding years; the highest "fever" death-rates last month were recorded in the City of Westminster, Hackney, Shoreditch, Bethnal Green, and Poplar. The 34 fatal cases of diarrhœa were 21 below the corrected average number; this disease was proportionally most fatal in Holborn, Shoreditch, Stepney, Poplar, and Greenwich. In conclusion, it may be stated that the aggregate mortality in London last month from these diseases was nearly 22 per cent. above the average.

Infant mortality in London during February, measured by the proportion of deaths among children under one year of age to registered births, was equal to 144 per 1000. The lowest rates of infant mortality were recorded in St. Marylebone, Stoke Newington, Hackney, the City of London, Southwark and Deptford; and the highest rates in Chelsea, St. Pancras, Finsbury, Poplar, Bermondsey, and Greenwich

# Correspondence.

"Audi alteram partem."

## THE SUBJUGATION OF SMALL-POX: NOTIFICATION.

*To the Editors of* THE LANCET.

SIRS,—The small-pox question, as discussed by you in your leading article in THE LANCET of March 8th, p. 678, carries my mind a long way back in my own experience. In 1863, very shortly after my appointment to be medical officer of Glasgow, we were confronted with a rising epidemic of small-pox which had to be met by means largely extemporised and by a preventive staff—not to speak of a very inchoate state of the local and general sanitary acts—very inferior to those now in operation. Nevertheless, by diligent and specially organised house-to-house vaccination and revaccination (taking this, for the nonce, altogether out of the hands of the Poor-law authorities); by public disinfection (then freely carried out at the public expense for the first time); by segregation of the sick and careful watching (as far as was possible to us) of suspects; we had the satisfaction, not only of keeping down and ultimately extinguishing this particular epidemic, but of laying the foundations of a preventive organisation which, improved by experience, succeeded in keeping Glasgow for a good many years absolutely free from small-pox. It was apparent to us at that time, and was confirmed later by Dr. J. B. Russell, that the most dangerous cases from the sanitarian's point of view were not the severe but the mild cases, and particularly those in which the diagnosis was obscure and in which, after a brief premonitory fever and a few insignificant-looking spots, all the symptoms subsided, so that the patient was able to go about his ordinary occupation and perhaps never came to know what was the disease he had at all. I remember a case of this kind among what may be called the better ranks (socially speaking) which occurred after I had ceased to be medical officer of the city but which was carefully traced out in detail by my successor, Dr. Russell. A gentleman connected with one of the most flourishing shops in the most *shoppy* street in Glasgow (Buchanan-street) came home from Paris with what was supposed to be a feverish cold. He sent for his private medical adviser, who arrived, prescribed, and left him under the impression above-mentioned, and did not (as I was informed) visit him again. Next day a few insignificant acne-like spots had appeared on the face, but all discomfort was gone and the patient regarded himself as quite well, *taking no precautions whatever.* To this single case, moving in the best society, I was credibly informed that from 12 to 20 cases subsequently were actually traced in different quarters; and in all probability those so traced were only a fraction of the whole. Now it must be admitted that although "notification" was in those days unknown, or at all events not practised, it might very well have been that an isolated case like that of Mr. B might have escaped notification without much blame to anyone. But this, and other incidents which I have always had in mind since, have pressed home with me the conclusion that I have endeavoured (hitherto, I fear, unsuccessfully) to ventilate in your columns; that in "notification" it is a mistake to stipulate for the *name* of the disease as the essential fact to be notified, and that the mere suspicion or reasonable presumption of an infectious disease, however arising, ought to be accepted as a valid notification in law and should be invited, if not compelled, not only from the medical man in attendance but from all who are interested or implicated in the case, as a basis for fuller investigation. Suppose that the medical attendant of Mr. B had paid him just one more visit it is very probable that, if not well versed in small-pox, he might still have had a doubt as to the disease; but he could hardly have seen even the few traces of an exanthem without suspecting *something* infectious, and that something, I would say, he should be held bound to communicate *at once,* leaving the completion of the diagnosis. Perhaps it might have been chicken-pox? What then? Because chicken-pox has not been enumerated (wrongly, in my opinion) in the Notification Act, is it expedient that all the ambiguous cases which occur should wait for complete verification before being notified as small-pox? I am glad to read in your leader that the authorities in London have come to a different conclusion upon this point, and I hope that before they are done they will see the expediency of bringing about some further reforms in the Notification Act in accordance with the views that I have submitted.

I am, Sirs, yours faithfully,
Edinburgh, March 8th, 1902. W. T. GAIRDNER.

## THE HOUSING OF THE POOR.

*To the Editors of* THE LANCET.

SIRS,—The valuable work which has been done during the past 20 years by the Mansion House Council on the Dwellings of the Poor is not too well known. By voluntary effort it has successfully grappled with the most pressing need of our time—the housing of the poor. It has received the approval of the most earnest and practical of the men and women of the day, and it has won the confidence of the poor themselves. The numerous urgent letters constantly received by the Mansion House Council demonstrate the necessity of its continued existence.

I have to ask the public for funds in order that this useful work may be efficiently maintained. The help solicited is pressingly needed and I trust may be heartily and generously rendered. To those who have not hitherto contributed to the movement, it may be well to say that the health and well-being of the very poor and the increased comfort and improved sanitary condition of the dwellings of the wage-earning class are some of the many benefits which have resulted from the Council's labours.

Contributions may be sent to me here or to Messrs. Prescott, Dimsdale, and Co., the bankers of the society, 50, Cornhill, and will be duly acknowledged.

I am, Sirs, yours faithfully,
JOSEPH C. DIMSDALE,
Lord Mayor.
The Mansion House, London, E.C., March 10th, 1902.

P.S.—A report of the Council will be forwarded to anyone interested in the subject upon application to the honorary secretary (Mr. John Hamer, J.P.), 31, Imperial-buildings, Ludgate-circus, E.C.

## THE PSYCHIATRIC CLINIC.

*To the Editors of* THE LANCET.

SIRS,—It is reassuring to note that the position assumed, in THE LANCET of March 1st, p. 622, by your Scottish correspondent in reference to the proposed psychiatric clinic in Edinburgh is not in accordance with your deliberate finding on this important question in THE LANCET of Feb. 1st, p. 318. The question clearly does not affect Edinburgh alone, but must sooner or later be discussed in the various general hospitals of the country where there is scope for the treatment and teaching of psychological medicine. It is impossible within the limits of a brief letter to place the facts before your readers with all relevant details. Broadly, this country is not abreast of continental practice; an important class of patients is not reached; a field of medical observation and research is untilled; a definite benefit is withheld from the country at large so long as these proposals are neglected. It is not a new question. When the Edinburgh Royal Infirmary was being built Sir Arthur Mitchell appealed for the institution of a special department for mental disorders; 30 years ago Sir John Sibbald urged that such a course was desirable; and from time to time others have not been unmindful to plead for the poorer class of mental patients on the lines indicated.

I traverse the observations and conclusions of your correspondent from first to last, and regret that at this time of day they should have found a place in the authoritative columns of THE LANCET. The meeting of the Medico-Chirurgical Society was widely representative, and the resolution of approval proposed by Sir John Batty Tuke was adopted *nem. con.* Indeed, there were no objections raised in discussion except on questions of finance, which, of course, must be dealt with after the principle is adopted. While financial considerations are of importance to the managers of the infirmary and to the promoters, and constitute difficulties to be surmounted, the purport of the medical

# THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeons: J. Crowley to the *Bulwark;* R. E. Biddulph to the *Hibernia*, and W. G. K. Barnes to the *Duke of Wellington*. Staff Surgeons: R. F. Bowie to the *Gibraltar;* E. St. M. Nepean to the *Empress of India;* W. G. Stott to the *Melampus;* R. Hickson to the *Prince George;* J. Andrews to the *Monarch* for Ascension Hospital; J. McC. Martin, D.S O., to the *Cambridge;* E. H. Meaden to the *Amphitrite;* and P. V. Jackson to the *Charybdis*, additional. Surgeons: W. E. Marshall to the Haulbowline Hospital; T. B. Shaw, lent to Portsmouth Division R.M.L.I.; A. C. Renwick to the *Bulwark;* H. L. Penny to the *Benbow;* L. S. Whitwam to the *Dwarf;* A. A. J. McNabb to the *Collingwood*· L. E. Dartnell to Hong-Kong Hospital; A. T. Wysard to the *Ganges;* C. L. W. Bunton to the *Forte*, when recommissioning; F. D. Lumley to the *Amphitrite;* J. Whelan to the *Partridge;* and S. Conner to the *Empress of India*.

### IMPERIAL YEOMANRY (IN SOUTH AFRICA).

John Henderson Wright to be Medical Officer, with the temporary rank of Captain. Dated Jan. 14th, 1902.

Arthur Ricketts, C.M.G, to be Medical Officer, with the temporary rank of Captain Dated Feb. 4th, 1902.

T. J. S. Suffield to be Medical Officer, with the temporary rank of Captain. Dated Jan 20th, 1902.

John Edward Williams to be Medical Officer, with the temporary rank of Captain. Dated Feb 3rd, 1902

### ROYAL ARMY MEDICAL CORPS.

Major D. R. Hamilton proceeds to Colchester for temporary duty. Lieutenant-Colonel E. L. Maunsell is appointed to the charge of the Station Hospital at Fyzabad. Lieutenant-Colonel P. J. Dempsey takes over charge of the Station Hospital, Portsmouth.

### INDIA AND THE INDIAN MEDICAL SERVICES.

The King has approved of the following promotions among officers of the Indian Staff Corps:—To be Lieutenants (dated Jan. 29th, 1902): Alfred Ernest John Lister, Thomas Samuel Beauchamp Williams, Samuel Herbert Lee Abbott, Alexander William Greig, Richard Ernest Lloyd, John Edmund Clements, Hugh Barkley Steen, Ernest Bisset, Richard James Bradley, James Woods, Alexander William Overbeck-Wright, David Munro, Ernest Archibald Loch, Thomas William Harley, William John McCoy, Roger Lionel Hagger, Robert Markham Carter, Roger Durrant Willcocks, Thomas George Ferguson Paterson, Dodington George Richard Shurton Baker, Jaspar Robert Joly Tyrrell, [illegible] Ganpat Rai, Robert Macpherson Barron, William Reith Scroggie, Lewis Patrick Farrell.

The King has also approved of the retirement from the service of the undermentioned officers:—Madras Establishment: Lieutenant-Colonel Arthur Theophilus Lodge Patch, dated June 19th, 1901. Lieutenant-Colonel Jamshedji Kharshedji Kanga, dated Dec. 14th, 1901. Bengal Establishment: The retirement of Lieutenant-Colonel E. Bovill has effect from Nov. 9th, 1901, and not as notified in the *London Gazette* of Jan. 17th, 1902.

### IMPERIAL YEOMANRY.

The under-mentioned officers resign their commissions and receive new commissions subject to the provisions of the Militia and Yeomanry Act, 1901, each retaining his present rank and seniority:—

Derbyshire: Surgeon-Lieutenant R. M. Wilson.

Suffolk (The Duke of York's own Loyal Suffolk Hussars): Surgeon-Lieutenant-Colonel A. Cooper.

Bedfordshire: Henry Skelding to be Surgeon-Lieutenant.

Royal East Kent (The Duke of Cannaught's Own): Robert Leishman Moorhead to be Surgeon-Lieutenant.

Shropshire: Surgeon-Major J. D. Lloyd to be Surgeon-Lieutenant-Colonel.

### VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers):—9th Lancashire: John Holt Marsh to be Surgeon-Lieutenant.—1st North Riding of Yorkshire: Surgeon-Lieutenant P. B. G. Considine resigns his commission.

Submarine Miners (the Tees Division).—Surgeon-Captain J. W. Edwards resigns his commission.

*Rifle:* 4th (Nottinghamshire) Volunteer Battalion, the Sherwood Foresters (Derbyshire Regiment): Brigade-Surgeon-Lieutenant-Colonel F. H. Appleby is seconded whilst holding the appointment of Senior Medical Officer to the Sherwood Foresters Voluntary Infantry Brigade. 1st (Ross Highland) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, the Duke of Albany's): The under-mentioned officer resigns his commission: Surgeon-Lieutenant D. Lamond, dated 12th March, 1902

### ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

The Woolwich Companies: Major F. L. Stephenson to be Lieutenant-Colonel, and to command under paragraph 55A Volunteer Regulations.

### SOUTH AFRICAN WAR NOTES.

Colonel Townsend, R A.M.C., is reported dangerously wounded in the shoulder at Klip Drift on March 7th but doing well March 10th.

Lieutenant J. Clarke, R A.M.C., and Civil Surgeon Stephen are on passage home in the s.s. *Ulstermore* which left Cape Town on March 1st. Lieutenant W. C. Stevenson, R.A.M.C., and Civil Surgeon Stoney are on passage home in the s.s. *Guelph* which left Cape Town on the same date.

### DEATHS IN THE SERVICES.

Surgeon-Major Francis Turnbull, I.M.S. (retired), aged 82 years, at his residence in London.

Lieutenant-Colonel Arthur Robert Wyatt Sedgefield, I.M.S., on March 8th, at Sanawar, Punjab, India, aged 47 years. He was appointed surgeon in 1880 and was promoted lieutenant-colonel in 1900

Fleet-Surgeon Ernest Elliott (retired) on Feb. 27th, at Southsea, aged 84 years. He was appointed surgeon in the navy in 1841.

Brigade-Surgeon-Lieutenant-Colonel Edward Ambrose Fitz-Gerald, late I.M.S. (retired), aged 67 years, on March 9th, in London.

Percy Reginald Fort, M.R.C.S. Eng., L.R.C.P. Lond., Civil Surgeon to the South African Field Force, who died at Standerton on Feb. 10th from an attack of enteric fever, was born in 1874 and was educated at the Merchant Taylor's School, London, and at St. Mary's Hospital Medical School. After qualifying in 1900 he was appointed a medical officer at the York Dispensary, but resigned that post in order to take service in connexion with the war. He sailed for South Africa in July, 1901, doing duty on the hospital ship *Simla* and made two voyages in the same vessel. He was then appointed to the medical charge of the 8th Mounted Infantry in Colonel Rawlinson's column and it was while so employed that he contracted the fever from which he died.

### SCARLET FEVER ON H.M.S. "IMPREGNABLE."

The scarlet fever epidemic on the training ship *Impregnable* at Devonport not having diminished it has been decided to transfer the boys and crew to the *Inconstant*, overflow ship attached to the naval depôt, in order to allow the thorough disinfecting of the *Impregnable*.

A display of Military and Musical Drill by selected companies of the Church Lads Brigade will take place at the Guildhall on Tuesday, April 15th, at 8 P.M., when the Duke of Fife will preside.

**PRESENTATION TO A TEACHER OF DEAF-MUTES.**—An interesting meeting of adult deaf-mutes of both sexes and their sympathisers was held on Sunday afternoon, March 9th, in the New Synagogue, Great St. Helen's, Bishopsgate, E.C, for the purpose of presenting to the deaf-mutes' former teacher, Dr. S. Schöntheil, an embossed silver bowl as a testimonial to his important services in improving the methods of teaching the deaf and dumb and promoting the efficiency of their teachers. Dr. S. Schöntheil was for 22 years headmaster of the Jews' Deaf and Dumb Home, formerly at Notting Hill but now at Wandsworth Common, and since his resignation in 1893 has been devoting himself to the education (primary and secondary) of deaf and dumb children of the upper and middle classes.

were evidences of vesiculation and umbilication. We decided that the case was probably small-pox and the patient was therefore isolated in hospital and the remainder of the family were vaccinated. During his stay in the hospital he completed an undoubted, though mild, case of true small-pox. The correctness of the diagnosis was further clinched by the fact that two attempts at vaccination were made when the skin had practically regained its normal condition, and both had failed. The closest possible inquiry failed to reveal any local cause of infection, and, indeed, no case of small-pox had occurred in this neighbourhood for about a year previously to this, nor has any case arisen up to the present time since then. I made inquiries at the patient's workplace and through the courtesy of the managing director saw the process in which he was engaged. I was also kindly furnished with the address of the place from which the cotton was imported and on writing to the State health officer of that locality I received the following reply :—

> Quarantine Department, Austin, Texas.
>
> DEAR SIR,—Yours of the 15th instant received. Small-pox is quite prevalent on the cotton plantations, not only of Texas, but of all the southern States It is of such a mild form as a rule as to not require medical attention, and in many cases the victim will pursue his ordinary work in the cotton-field throughout the attack. That the cotton is thereby infected cannot be doubted, as the workmen of several cotton-gins have been infected through the cotton. Wherever the health authorities become aware of the infection of cotton it is either disinfected or destroyed. But you will readily see by the preceding that there will be many instances of infection that will not come to their knowledge. If it will not appear presumptuous I will make the suggestion that your factory operators should all be thoroughly vaccinated. Very truly,
>
> (Signed) A. F. BLUNT, M.D.,
> State Health Officer of Texas.

The last remark of Dr Blunt is worthy of recommendation to any medical officer of health whose energy is likely to prove equal to the demand.

I am, Sirs, yours faithfully,
MEREDITH YOUNG,
Medical Officer of Health of the County Borough of Stockport.
Stockport, March 5th, 1902.

## CARDIAC PAIN.

*To the Editors of* THE LANCET.

SIRS,—In the report in THE LANCET of March 1st (p. 592) of the discussion upon Dr E. Markham Skerritt's paper upon cardiac pain read before the Medical Society of London more than one speaker is mentioned as having referred to the occurrence of pain in aortic regurgitation, but apparently it was not suggested that the most important lesion in these cases is probably the same as in those in which there is no valvular disease. The aorta immediately above the aortic valve is diseased in the majority of fatal cases of aortic regurgitation occurring in the later half of life, the orifices of the coronary arteries are often obstructed, and as a consequence of this obstruction there is fibrosis of the cardiac muscle It is probable that the disease of the heart-wall rather than the valvular lesion is mainly responsible for the attacks of cardiac pain. As Dr. H. D. Rolleston remarked, in cases of aortic stenosis due to calcareous diseases of the aortic valve the aorta is generally healthy, yet fibrosis of the cardiac muscle may also exist in these cases, and when pain is associated with aortic stenosis fibroid degeneration of the myocardium is probably present. The general opinion of the meeting appears to have been that severe cardiac pain is not common. This is doubtless true, but the nature of the milder cases is probably very similar to that of the more severe In cases of cardiac pain associated with anæmia, and not uncommonly in those cases which may be attributed to the referred pains of dyspepsia, the various situations in which pain is felt are the same as those of angina pectoris, even to its extension to one or both arms. There are also the same localised areas of tenderness, and an interesting feature which I do not remember to have seen mentioned is the occasional presence of slight pain in swallowing referred to the region of the lower third of the œsophagus, no doubt where it passes behind the pericardium. In anæmia we know there is temporary weakness of the cardiac muscle, and it is possible that in dyspepsia also much of the pain considered to be referred pain may indicate disturbance of the heart-muscle, not by reflex irritation, but as a consequence of poisoning by abnormal products of digestion. Why the pain should only occur in some people and in them be generally spasmodic is a wider question. It has been my intention here merely to suggest that in all cases of cardiac pain, whether slight or severe, there is either permanent lesion or temporary disturbance of the cardiac muscle.

I am, Sirs, yours faithfully,
THEODORE FISHER.
March 4th, 1902.

## SMALL-POX AND VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—In a recent issue you print, under the above heading, a letter from a correspondent suggesting that the Government should supply lymph to vaccinators. It will interest him to know that the New Zealand Government, through the Health Department, supplies medical men free not only with vaccine but with the various serums and antitoxins. Our Government also undertakes free bacteriological examinations of tissues, &c., and reports on the same to the sender. I am, Sirs, yours faithfully,

F. W. GALE, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A.
Kaikoura, New Zealand, Jan. 20th, 1902.

## THE DIPLOMA OF THE SPECTACLE-MAKERS' COMPANY.

*To the Editors of* THE LANCET.

SIRS,—It has been brought to my notice, as Master of the Spectacle-Makers' Company, that reports are circulated to the effect that candidates for the diploma of this Company are examined in sight-testing and that the diploma certifies that the holder is competent, by virtue of such examination, specially to undertake cases of refraction. I therefore wish to state most emphatically that the examination does not include sight-testing, but deals generally with theoretical and applied optics, spectacle-making and frame-fitting, heat and elementary mathematics, and so ensures that the holder has an intelligent knowledge of his trade.

Any holder of the diploma of the Spectacle-Makers' Company may carry on the general business of an optician in the ordinary way ; but in reference to spectacle-fitting particularly he is bound by certain restrictions, as you may see by the inclosed copy of the declaration which he signs. Thanking you in anticipation of your publishing this statement, I am, Sirs, yours faithfully,

W. HART DYKE,
Master of the Spectacle-Makers' Company.
Temple-avenue, E.C.

## SOCIETY OF LICENTIATES AND MEMBERS OF THE LONDON ROYAL COLLEGES.

*To the Editors of* THE LANCET.

SIRS,—I should esteem it a favour if you would allow me to make known through the columns of THE LANCET that the secretaries of the above society have this week posted to every L.R.C.P., M.R C.S. who has not already a degree in medicine a copy of the petition to the Royal Colleges asking the Royal Colleges to consider the disabilities of their petitioners. The secretaries would be glad to receive signatures as soon as possible that the presentation may be proceeded with. As it is very important that the petition should be as numerously and as influentially signed as possible we hope that all Licentiates and Members will sign quite irrespective of whether they belong to the society or not. I am, Sirs, yours faithfully,

FREDERICK J. SMITH,
President and Treasurer of the Society.
Harley-street, W.

*To the Editors of* THE LANCET.

SIRS,—May I venture to ask what is the position of an L.R C P. Lond. with regard to the objects aimed at by the Society of Licentiates and Members of the London Royal Colleges? Is it necessary in order to become a member of the society to be the possessor of the conjoint diploma, and is he who holds merely the diploma of L.R.C.P. Lond., to be precluded from enjoying the benefits of the reforms which the society has been established to secure—if possible? The Royal College of Physicians of London used regularly to advertise that its diploma was a qualification in surgery as well as in medicine and midwifery, in fact, a *lete* qualification, and this claim, I fancy, has bee l by the College meeting was to debate the propositions from the medical point of view The result was entirely satisfactory to those of us who have long been convinced and importunate for the scheme If it were in the mind of anyone at the meeting to propose that general physicians should be appointed, to the exclusion of specialists, in attendance on cases of incipient and transitory cases of mental derangement, why did he not speak out? For myself I would not have act or part in the matter if the department of medicine to which I have given my life were to be passed over in that contemptuous fashion The suggestion is an evil echo of the bad old days You will remember that the proposals of the London County Council for the establishment of a psychiatric hospital were wrecked on this rock of offence, and right gladly and willingly I stood in with the wreckers What is known of insanity (the various physical diseases issuing in mental disorder) is the outcome of specialist work and our proposals to enlarge that work rest upon our claims as physicians and on no other ground

Will you persuade us that ophthalmic operations are to be *handed over to the general surgeon*? *Or will you offer us* appointments in gynæcological spheres of interest? The proposition is absurd It has ever been a stumbling-block to the British public that a man may do more than one thing well Herein, indeed, lies a vulgar error So, there was much wisdom shown by a well known surgeon when he issued his powerful etchings with the Horatian quotation —

> 'O laborum
> Dulce lenimen '

Thus, the asylum physician is obscured in his palatial environment even to his fellows, who should really know better.

Too much is made of the asylum "stigma" As years pass these institutions are becoming recognised as true hospitals, and it is commonly admitted that hundreds are being sent to them who formerly would never have passed their doors I will not labour that point The same "stigma" *attaches to tuberculosis or cancer*

Any innovation is received with diffidence It must often win its way through contempt and objurgations, but if it is founded on justice and common sense it will in the end be generally accepted This proposal *is* founded on justice If a man be rich enough to command the services of a consultant in mental disorders he is in no difficulty If he be poor that door is not open to him Your correspondent writes in ignorance of what has been done at St. Thomas's Hospital by the establishment of an out patient department in psychiatry years ago It is a success, still more valuable would be an in patient ward It has been a success, and we press for the logical development

I shall pass over the establishment of psychiatric clinics at all the German universities and briefly refer to what has been done at Copenhagen, where the circumstances are nearly similar to those of Edinburgh Many years ago when the Hospital Commune was rebuilt, two pavilions were erected for the reception of mental and neurological patients, and these pavilions were placed under the care of Professor Pontoppidan There, again, the results have been eminently satisfactory Many cases never proceed to the asylums of Denmark, the study and investigation of mental maladies have been notably advanced, and the students of the University see cases which would otherwise have escaped their notice Or, to come nearer to Edinburgh, the Barony Parish of Glasgow established observation wards in their poorhouse under the care of a physician of experience in asylum life with the result that a separate institution is now to be built Glasgow does not advance on theoretical considerations only, the practical results of tentative experiments appeal to that business community, and the Barony wards are therefore being developed as a special hospital Will Edinburgh lag behind? I think not The traditions of its medical school are entirely favourable to progress and efficiency, to maintain a position in the front rank. We desire to see a psychiatric clinic established in the Royal Infirmary for the public benefit, for the advancement of science and for the whole hearted instruction of medical students To that end the physician and teacher must be a man who has devoted himself to the study of these disorders, and no other He must be a man of proved ability in observation, research, and expression—in short, a specialist of eminence That is fundamental. The question of ways and means, although important is not a question of principle It falls to be considered with other primary details

In my relations with general practitioners especially those working in country districts, I stand appalled by the magnitude of their responsibilities Face to face with problems of life and mind, they emerge with credit hardly won and often slightly recognised The range of medical and surgical work is vast and daily more complicated in practical difficulties Perhaps to those of us who are engaged in specialised work this is more apparent Yet a specialist must ever be on guard against the limitations of his work and keep in touch with the great world of medicine Assuredly he will not reach success if these limitations overmaster him Here is a scheme which will knit psychiatry to general medicine where hitherto we have had to deplore loose ends On these grounds I ask you to continue your powerful support I am, Sirs, yours faithfully,

Perth, March 1st 1902 A R URQUHART

### *To the Editors of* THE LANCET

SIRS,—In the remarks on the special meeting of the Edinburgh Medico Chirurgical Society with reference to this matter the observation is made that if such a clinic is established it should be under the care of a "general physician" On this line of reasoning the eye wards should be under the care of a general surgeon The argument that if an alienist had charge the wards would be regarded as "mad wards" is, I think, erroneous At St Thomas's Hospital, where for several years past an out-patient department for mental diseases has been established, I believe that there is very little feeling amongst the patients that they are regarded as mad or *that others regard them as "mad" patients*; the recognition of mental disease as associated with other disease has, I believe, already grown and will continue to grow

In correspondence relating to the London reception houses recently proposed I note that the workhouse infirmaries claim that they already supply the want, but it must be borne in mind that a large proportion of the class of cases who would be saved from complete mental breakdown by a few days' treatment in a psychiatric clinic or reception-ward will not voluntarily go to the Poor law infirmary or to the asylum as boarders They and their friends often beg piteously to be admitted to the hospital, but this in the absence of a specially organised ward it is impossible to recommend

"Insanity is a preventable disease" and its prevention lies in getting those who are evolving it to come under skilled care in the incipient stage If an alienist is needed to treat the fully developed disease, as admitted to the asylums, still more is one required to detect and to treat it in its earliest, often most insidious, stages If a tenth part of the enormous outlay on palatial asylums were devoted to the prevention of mental disease, some of these grand institutions, at once the pride and shame of civilisation, might in a few years be eligible for other purposes

Alienist physicians have been frequently attacked for many years past as being unscientific, and during that time I have accumulated a large number of notes of cases which have ultimately come under my notice after treatment by the "scientific and even eminent physician" If I could submit them to you, Sirs, I believe that you would agree with me that at least in many instances, a grievous wrong had been inflicted by persons unskilled in mental disease undertaking its treatment I therefore demur to the psychiatric clinic being placed under a general physician

I am, Sirs yours faithfully,

March 10th 1902. HENRY RAYNER, M D Aberd

## SMALL-POX INFECTION BY MEANS OF RAW COTTON

### *To the Editors of* THE LANCET

SIRS—The following case illustrates I venture to think, an unusual method of infection in cases of small pox The patient, a young man aged about 23 years, worked in a large cotton spinning mill here, opening the bales and feeding them into a machine for the first stage in the spinning process He worked in a large room with only one other man On a certain date he began to feel ill—had headache, slight feverishness and marked backache, three days later a papular rash appeared and his medical attendant was called in For two days the medical attendant was uncertain as to the nature of the illness, and *then fearing the worst* asked me to see the case with him At that stage there was still some little doubt as to the precise nature of the ailment, but there

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *The Victoria University Question.*

THE graduates and the undergraduates of the Victoria University are giving utterance to their hopes and fears in the daily press. Some lament the triple split of the "triplets," while others think it the best thing that could happen. Some of the graduates fear the loss of value that may ensue to the degree of an extinct university, while the undergraduates do not feel sure that the Manchester degree will equal that of the Victoria University. There was a meeting of women undergraduates of the Owens College on Feb 21st at which the opposing views were very vigorously set forth. A proposition was moved—"That this meeting supports the action of the court of Owens College with reference to the university question." That is of course in favour of the happy despatch. An amendment was then moved as follows: "That we regret the action of University College, Liverpool, and would regret the dissolution of the Victoria University." This was carried by 46 votes to 29, and was also passed as the substantive motion. The lady who moved the original proposition then expressed a wish that her motion should also be voted on, and the (lady) chairman allowed this, with the result that it also was carried by 34 votes to 26. This somewhat amusing result shows that though no doubt these ladies are all admirably adapted for "home rule," it is not clear that they are equally well able or willing to submit to the rules and trammels of public meetings. As a sequel to this meeting one of the ladies wrote to the press "to explain that the contradictory conclusion apparently arrived at was due to the fact that the chairman persisted in putting the original motion to the meeting after the amendment had been carried as a substantive resolution, in consequence of which many refrained from voting." This was followed by a rejoinder from the "chairman," stating that the terms of the resolution and amendment were such that there was nothing inconsistent in voting for both.

### *The Cheadle Lunatic Asylum.*

The Cheadle Asylum is a branch of the Manchester Infirmary and at the last annual meeting of the trustees its condition came under review. In 1881 there were in the asylum 186 patients and an indoor staff of 112. There are now 358 patients and an indoor staff of 212. Great improvements have been made during the past year in the main buildings and their surroundings with the very proper view of making them as attractive as possible. A new block is in course of construction at a cost of £20,000, to contain 70 persons, which is sure to be filled as soon as opened. The statistics given in the report would seem to show that drink and mental worry were the two chief causes bringing patients to the asylum. A large proportion are classed under the heads of "ladies" and "gentlemen"—i.e., persons of no occupation—and the chairman observed: "This would almost justify one in coming to the conclusion that idleness was a fertile source of mental worry and drink." It is probable that the Cheadle Asylum is the largest private institution of its kind in this country. It was announced at the annual meeting of the trustees of the infirmary held on Feb. 14th that Dr. T. Harris and Dr. Judson S. Bury were appointed visiting physicians to the asylum for the ensuing year.

### *The late Dr. D. J. Leech.*

An interesting event took place in the Christie Library of Owens College on March 4th. On behalf of a number of subscribers Dr. J. Dreschfeld presented to the College a portrait of the late Dr. D J. Leech, Professor of Materia Medica and Therapeutics. He spoke of the services rendered by Dr. Leech to the college through a long course of years, of his scientific attainments, his professional qualities, and his private character, and said that he did much to make the college and the medical school what they are to-day. Mr. Alderman Thompson, speaking for the college, "accepted most thankfully the portrait of one whom they all respected, loved, and revered." He alluded to the time when the relations between the infirmary and the Owens College were a little strained, and said that at that difficult time Dr. Leech did much to avert the danger of rupture. Mr. Alfred Hopkinson, the Principal, expressed sincere thanks to the subscribers, who comprised professional men, patients of Dr. Leech, and former pupils, not only in the United Kingdom, but also in the colonies and America, for the action they had taken. The portrait, painted by Mr. T. Harcourt, is a very successful one although it had to be painted from the study of photographs.

### *Fatal Electric Shock.*

In view of the interest which is felt just now in the subject of fatal electric shocks it may be worth while to mention a case reported from Sheffield. A man who was an electrician's labourer went to the theatre with a companion, and in the lavatory, in a joke, got hold of an electric bracket with both hands when it gave way and he "received the full current of 200 volts. He shouted to his companion who pulled him down." "Doctors were called in," but he died in about 10 minutes. At the inquest, held on March 3rd, the opinion was expressed that "had he taken hold of the bracket with one hand he would only have received a shock, but as he had hold by two hands there was a complete circuit of the current through his body." If this report is accurate the case is in marked contrast—a charge of 200 volts being fatal—to one mentioned in Mr. Aspinall's paper in the last issue of THE LANCET, where a man received a 2000-volt shock from hand to hand and came round without assistance in about 25 minutes.

March 11th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *Small-pox.*

THE district of Ystalyfera, where the first cases of small-pox in South Wales occurred at the beginning of the year, is now quite free from the disease. Six fresh cases have been reported in Swansea, one patient being the chief sanitary inspector. There have been three deaths in Swansea up to the present time. Isolated cases of the disease have also occurred during March in Merthyr, Bangor, and Ebbw Vale.

### *The Supply of Vaccine Lymph.*

The Swansea and the Pontypridd boards of guardians have decided to supply glycerinated calf lymph to their public vaccinators when the Local Government Board supply is insufficient, but the Bridgend board, in a more niggardly spirit has refused to provide any. It is a great pity that the Local Government Board was not more precise in the communication addressed to boards of guardians which stated that the Board would be prepared to sanction any reasonable expenditure incurred in the purchase of lymph required by public vaccinators.

### *Notification of Phthisis.*

The Local Government Board has suggested to the Llangyfelach Rural District Council that a scheme of voluntary notification of cases of phthisis should be adopted within the council's area in preference to adding the disease to those compulsorily notifiable under the Infectious Disease (Notification) Act, 1889.—The Oystermouth Urban District Council has decided to take steps to procure the notification of cases of phthisis occurring within its district.

### *The Sale of Food and Drugs Act at Bristol.*

During 1901 there were submitted to the analyst of the city of Bristol 732 samples of food, &c., a proportion of one sample to 449 persons in the city. Of the 259 samples of milk taken 18 were condemned, and 18 of the 377 samples of butter examined were found to be impure Convictions ensued in all these instances except one where a warranty was produced. There was no adulteration found in any articles examined except milk and butter. For the Departmental Committee on Food Preservatives 61 samples of food were taken in Bristol and 26, or 42 6 per cent., were found to contain preservatives.

### *Bristol Royal Hospital for Sick Children and Women.*

This excellent institution, which has accommodation for over 100 patients, is in a much better financial position than it was in a year ago. For several years the expenditure has exceeded the income by about £800 yearly, but a large bazaar organised by the Duchess of Beaufort in the summer of 1901 not only cleared off the accumulated debt of previous years, but left the managers with an adverse balance at the end of 1901 of only in the Law Courts But so far as I can see those in a similar position to my own are now to be left

OUT IN THE COLD.

## ACUTE SUFFOCATIVE PULMONARY ŒDEMA.

*To the Editors of* THE LANCET.

SIRS,—I think that the manner in which Dr. J. L Steven has presented his criticisms in THE LANCET of March 8th, p. 698, is somewhat unfair to Laennec and calls for a word in reply. He states that Laennec is dealing with a catarrh affecting the mucous membrane of the lungs, whereas he (Dr. Steven) is describing a pulmonary œdema. Now, making allowance for the state of pathology in Laennec's time, it may be remarked that when Laennec says the "lungs" he means the lungs and not the bronchial tubes, for he expressly states that the symptoms are due to a sudden inundation of the lungs with fluid. It is therefore beyond cavil that Laennec is describing an acute pulmonary œdema. Then when the points of difference which Dr. Steven describes as existing between the affection described by Laennec and that described by himself are closely examined it will be found that there is only one of these which can be fairly maintained, and that is, as to the duration of the symptoms. The two others—viz., that the expectoration in his cases (1) began at once and (2) was expelled with a hawk—though their great importance does not appeal to my mind—are, nevertheless, quite compatible with Laennec's statement. Laennec says· "*While* the suffocation lasts ...... the expectoration, *if any*, is altogether pituitous." The words "while" and "if any" warrant the inclusion of cases in which pituitous expectoration was present from the very beginning. As to the "hawking"—well, that depends very much on the patient Laennec says that there is little cough, and it is likely that he did not think it worth while to describe minutely the manner in which the fluid was expectorated, but he, at any rate, does not say that it was *not* hawked up. Dr. Steven also states that in one of his cases the suffocative symptoms and the expectoration ceased together, but in his second case there was catarrhal expectoration before the onset of the œdema which apparently continued right up to the patient's death. Therefore, as already said, the only point which holds is as to duration. But every disease differs in duration in different individuals; and will Dr. Steven or anyone else maintain that the duration of the symptoms in only two cases is enough to warrant the establishment of a totally different disease?

I am, Sirs, yours faithfully,

Henrietta-street, W., March 10th, 1902. A. G. AULD.

## BEEF WORM IN THE ORBITAL CAVITY.

*To the Editors of* THE LANCET.

SIRS,—I am much obliged to your correspondent Dr. George Ferdinands for calling my attention, in THE LANCET of Jan. 25th, p. 260, to a case of "beef worm in the orbital cavity" recorded by Dr. F. Keyt in the *British Medical Journal* of Feb 10th, 1900. Had I read Dr. Keyt's case I should obviously not have ventured the opinion that my own was unique There is not, however, anything "singular," as Dr. Ferdinands seems to imagine, in my not having read Dr. Keyt's notes on his case, as I do not take in the *British Medical Journal* and in this remote part of the world have no opportunity of seeing it. I am sorry that Dr Ferdinands's experience should lead him to express such pessimistic views in regard to the decadence of what he terms the "fairer courtesies which always existed between members of our profession", interesting as these views may be in themselves, however, I fail to see what bearing they have on the present case

I am, Sirs, yours faithfully,

THOMAS W. F. GANN.

Corozal, British Honduras, Feb 19th, 1902.

## THE DISSEMINATION OF KNOWLEDGE CONCERNING VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—Dr. Herbert W. G. Macleod, in THE LANCET of March 1st, p. 618, suggests public lectures illustrated by lantern slides showing typical cases of small-pox as a means of educating people on the importance and the advantages of vaccination. Such lectures have already been given in various places with very good success. We have prepared for such purposes some excellent slides showing typical cases of confluent, hæmorrhagic, discrete, and modified small-pox. They have been shown in Essex and are considered excellent. They will also be shown in Glasgow at an early date. We shall be glad to supply them at any time they may be wanted for public lectures by a medical man.

We are, Sirs, yours faithfully,

REBMAN, LIMITED.

129, Shaftesbury-avenue, Cambridge-circus, London, W.C.,
March 4th, 1902.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*The Plague Epidemic and the Famine.—Disastrous Seasons and their Effects on Crime and Mortality.—A Leprosy Conference.—Victoria Memorials.—Mandalay condemned as a Military Station.*

THE mortality from plague throughout India fluctuates from week to week. Last week it rose to 15,165, and for the past seven days it has gone down to 12,695 The disease is increasing in Bombay city, Karachi, and Calcutta, but has declined in the districts of Bombay and the Punjab. The deaths recorded are Bombay city, 568; the Presidency, 3830; Karachi, 49; Madras Presidency, 514; Calcutta, 120; Bengal Presidency, 738; North-West Provinces, 1506; the Punjab, 4113; Mysore State, 611; Hyderabad State, 144; and Kashmir, 500. Fresh centres keep declaring themselves. At Bhusawal the disease is very virulent and three cases have occurred at Agra.

The famine is still increasing. The latest returns show 307,157 persons in receipt of relief, of which number the Bombay districts return 183,000.

From certain facts given in the report of the Bombay Presidency it would seem that bad seasons are responsible not only for distress but for much additional crime and mortality. For the year ending July 31st, 1901, cognisable offences increased by over 10,000, and dacoities and highway robberies were nearly doubled. The distress caused by the famine helped to make the mortality the most disastrous on record. While plague carried off only 33,000, cholera claimed 163,000 victims, diarrhœa and dysentery caused 218,000 deaths, and fevers 500,000 These adverse influences affected Bombay city, where for the year under notice the mortality was at the rate of 102·25 per 1000—the total deaths being 79,350. It will be remembered that the famine chiefly affected the Bombay Presidency.

*At a recent conference* of the *Mission to Lepers* at Wardha, Central Provinces, it was resolved that leprosy was and should be considered contagious. The meeting expressed itself strongly on the necessity of strict segregation of the sexes, both married and unmarried, and that no untainted child over three years should remain in a leper asylum with its diseased parents These resolutions are the result of wide experience, for the operations of the society extend over 48 centres. It has 27 asylums and 14 houses for untainted children.

The memorials to Queen Victoria in the different cities of India will be very varied. In Bombay they talk of having a school for the blind, in Bangalore a technical institute, and in Lahore a statue The Church party in Mandalay has managed to secure an English church, the erection of which, strange to relate, has been subscribed to by numerous sects and creeds In Calcutta there is to be a memorial hall built of marble and of large dimensions, with extensive ornamental grounds. At Colombo it is proposed to have a school for the blind

Mandalay is likely at last to be given up as a station for troops. One company of infantry has already been shifted to Maymyo The former place has been frequently reported upon for its unhealthiness. The drainage and the situation of Fort Dufferin are bad and an epidemic of ague of a severe type occurred there in 1900, rendering one regiment completely unfit for active service The cantonment is built practically within a marsh. The water-supply is liable to every possible contamination. The unhealthiness of Mandalay is not a thing of to day—it has been known for years.

Feb. 21st.

Trust by the Aberdeen University Court is of considerable length and is subdivided into seven sections. The sums suggested under this heading are exclusive of any existing endowment for the purpose named, but are inclusive of annual grants from the general grants of the University (about £940) and from public bodies (about £350). A considerable part of the grants from public bodies is likely to be withdrawn. Under Section II. (Science and Medicine), Section V. (Research and Travelling Scholarships and Fellowships), and Section VI. (Other Purposes) the following items are specified, together with their annual cost: chair in Public Health, £950 to £1000; lectureships in Astronomy, Physiological and Pathological Chemistry, Medical and Surgical Electricity, Embryology, Art and Architecture, £1200 to £1500; lectureships in Mental Diseases, Ophthalmology, and Tropical Medicine, £750; research and travelling scholarships and fellowships in science, medicine, and arts, from £1500 to £2000; library, capital sum of £2000; laboratory equipment, capital sum of £10,000; upkeep of library, from £800 to £1000; and upkeep of laboratories and museums, from £1500 to £2000 —Lord Strathcona and Mount Royal, Lord Rector of the University, is to receive the freedom of the city of Aberdeen on April 9th. On the following day the graduation ceremony falls to be held in the Mitchell Hall of Marischal College —A meeting of the Sites and Plans Committee was held on March 7th for the purpose of considering the report which the senatus had obtained as to the accommodation required by the different professors and lecturers in their various departments in the extended buildings at Marischal College. The provision desired for the physiology department consists of a large lecture-room and seven other rooms; for the department of medicine the requirements consist of a class-room, a museum and laboratory, a retiring room, and a dark room; for pathology a plea is put in for an animal room; and for materia medica an additional research room is desired, also the enlargement of the museum, an animal observation room, a curator's room, and a storeroom. The general requirements consist of an examination room and a considerable increase of library accommodation. The matter was ultimately referred to the architect and a sub-committee, to report to what extent and at what cost it is possible to provide the desired accommodation.

### *Aberdeen Dispensary.*

The annual meeting of the managers and subscribers of the Aberdeen Dispensary, Maternity Hospital, and Vaccine Institution, was held in the town hall on March 7th, Lord Provost Fleming presiding. The report showed that the total number of cases treated during the past year was 11,810.

March 11th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The College of Science in Dublin.*

IN reply to the Member for South Belfast (Mr. W. Johnston, M.P.) the Chief Secretary said that it would be neither practicable nor desirable to remove the College of Science in Dublin to Belfast, the chief industrial centre in Ireland, as it was a national institution serving the needs of the whole country. The questions naturally arise, Why should scientific students in the north not have a college of science quite equal to that of Dublin, and why should the favours of the Crown in relation to the expenditure of public money be so largely confined to Dublin, a city with few industries and with a smaller population than Belfast, and in regard to the inhabitants of which Dr. W. K. Sullivan in his evidence before the Royal Commission on Technical Instruction, the report of which was issued in 1896, states, "The people of Dublin, who have been crying out for technical education lately, do not seem to know that they have had in their midst for the last 20 years one of the most complete polytechnic schools in Europe. If it has not done so much good as it might have done it is the fault of the people of Dublin." Under these circumstances the question is, Why should new buildings and an endowment of £8744 a year be given to Dublin and nothing to Belfast? But this is not all, for it appears that the museum in Dublin, handed over to the Agricultural and Technical Instruction Department by the Science and Art Department, South Kensington, with the College of Science, gets a yearly grant of £13,292, the Botanic Gardens receive an equal grant of £3842, while the Library receives £3732 a year. Dublin receives in connexion with the College of Science £29,680 per annum and Belfast, the great commercial centre of Ireland, not a penny. This great injustice to Ulster is felt to be a crying grievance and a campaign is being started so that the opportunities for higher scientific education shall not be confined to Dublin but shall be distributed in the provinces. What I say about Belfast applies equally to Cork. Why should those in search of higher scientific education in Cork be compelled to go to Dublin? The days of such absurd centralisation are surely now over. One of the Belfast newspapers asks "why it was that two eminent professors of the College of Science who offered to give evidence before the Royal Commission (on University Education) were not called," and hints that it was a desire to prevent disclosures about the causes of the backward condition of scientific and technical education in Ireland.

### *Royal College of Physicians of Ireland.*

The President and Fellows of the Royal College of Physicians of Ireland, at the monthly business meeting of the College held on March 7th, elected Dr. H. C. Drury as physician to Sir Patrick Dun's Hospital, in the place of the recently elected Professor of Institutes of Medicine, who has been exempted by the College from his hospital duties. It will be remembered that Dr. J. Mallett Purser, so widely known and appreciated by graduates in medicine of the University of Dublin during the last 20 years, was not only Professor of Institutes of Medicine but was also *ex officio* a physician to Sir Patrick Dun's Hospital. His office of professor at Trinity College was filled some weeks after his retirement. The post of physician to Sir Patrick Dun's Hospital has now been filled.

### *The Issue of Dispensary Tickets to Farmers.*

Dr. G. Evans, medical officer of the Plumbridge dispensary district, has written to the Strabane Board of Guardians stating that he had received a ticket for Poor-law medical relief for a farmer in good circumstances, with a £10 10*s.* Government valuation, and who, in his opinion, was able to pay a fee. The ticket was a 3*s.* one, and on it "5*s.*" was marked in and "3*s.*" was scored out. He thought that no guardian should tamper with tickets and he did not think that his fees should be fixed in such a way. He asked the guardians to cancel the ticket and to stop the practice. It was decided to cancel the ticket.

### *The Ulster Medical Society.*

The fifth annual meeting of the Ulster Medical Society was held in the Pathological Laboratory of Queen's College, Belfast, on March 6th, Professor W. Whitla, the President, being in the chair. The President showed a Heart with Mitral Stenosis with the history that a child with a well-marked presystolic murmur had, after running upstairs, been seized with sudden cardiac distress and the murmur previously present had disappeared and a mitral bruit took its place. The child subsequently died and the heart showed that the stenosed valve had ruptured and there were signs of recent valvulitis. Dr. A. Dempsey read notes of (1) a case of Acute Lymphatic Leukæmia; and (2) a case of Splenic Leucocythæmia Dr. Thomas Houston read a paper on the Blood in Cases of Glandular Tumours, Dr. C. E. Shaw gave a lantern demonstration on the Structure of the Fœtal Larynx, and Dr. J. A. Craig gave a lantern demonstration on the Mastoid Antrum. The meeting then adjourned for a fortnight, only about one half of the work on the programme having been got through.

### *Royal Commission on University Education in Ireland.*

The Royal Commission on University Education in Ireland is to visit Belfast on April 2nd, when it is expected that there will be a great deal of evidence tendered. No subject has given rise to greater discussion than the vexed question of the settlement of university education in Ireland, and the two Blue-books already published, with evidence taken before the present commission, demonstrate the extraordinary differences of opinion which exist on the matter.

March 11th

£67. In a city of the world-wide reputation for philanthropy possessed by Bristol there ought not to be any difficulty in securing a sufficient sum to meet the annual expenditure of £4600. The number of in-patients treated in 1901 was 608, or 23 fewer than in 1900, the reduction being due to the closing of the wards in the spring in consequence of outbreaks of scarlet fever and diphtheria. In the out-patient department 4414 patients were treated, an increase of nearly 200 over the number in the previous year. In the dental department 661 patients received treatment. There are in the hospital 34 cots either endowed or supported by special subscriptions.

### *The Workmen's Compensation Act.*

At the Cardiff County-court on March 7th, before his Honour Judge Owen, a claim for compensation was made by a widow against a firm of building contractors for the death of her husband, aged 65 years, a stonemason in their employ. The evidence showed that the deceased was at work on Sept 30th, 1901, when an electrically-driven crane collapsed and fell. He was so much frightened that although the nearest part of the crane to him at the time of the accident was 55 feet away he died from heart failure on Nov. 22nd. The facts were admitted, but it was contended that the applicant was not entitled to compensation for the results of an accident or shock from such an accident unless actual physical injury had been sustained. The judge held otherwise and awarded the widow £156.

(FROM OUR OWN CORRESPONDENTS.)

### *Royal Edinburgh Asylum for the Insane.*

THE statutory annual meeting of the corporation of the Royal Edinburgh Hospital for the Insane was held on Feb. 24th in the city chambers. The report by the ordinary managers showed that the ordinary revenue for the year amounted to £58,279 and the ordinary expenditure to £53,876, leaving a gross surplus revenue of £4403 Deducting from this £1828, the annual instalment towards liquidating the debt on the West House, a free surplus remained of £2574 Of this surplus there were derived from Craig House £2653, less a loss on intermediate and pauper patients of over £79. The cost of maintenance per head of the patients in Craig House was £124 16*s.* 8*d.*; that of intermediate patients £42 14*s* 6½*d.*, and that of pauper patients £33 2*s.* 4*d.*, including share of instalment towards liquidation of debt. The managers see no prospect of their being able to make any abatement in the rates chargeable for the intermediate and pauper patients, so that those rates will remain at £42 for the intermediates and £33 for the paupers, including clothing for the latter. The managers renew their complaint with regard to the overcrowding occasioned by the large numbers of patients sent to the asylum by the Edinburgh parochial authorities. The report of Dr. T. S. Clouston, the physician superintendent, stated that at the beginning of the year the patients numbered 970, including six on probation, while at the end of the year there were 962 patients, also including six on probation. There had been 441 admissions during the year, 215 having been men and 226 women The total number of patients under treatment had therefore been 1411, the largest number on record. 63 men and 60 women had died during the year. The number of rate-paid patients sent was 356, six more than the average of the past five years. There had been great difficulty in accommodating the patients sent, and it was only done by refusing almost all applications at the lower rate of board—a hardship and injustice to which he had directed attention for many years Arrangements had been made to board other 30 patients in the Hartwood Asylum, which would give slight relief for a few months to the overcrowded wards, but it would not enable the asylum to admit the deserving poor of the private class. With regard to the causes of insanity he had to point out that alcoholic excess was the most frequent of all the contributory causes of mental disease. That cause existed in one quarter of the whole admissions. The mental causes which upset sanity and many of the bodily causes acted much more strongly in individuals of sensitive, high-strung, sympathetic temperament than on those of strong and tough disposition. There were no possessions for which an average man or woman should be so thankful as a good nervous heredity, an education in self-control, a fair self-assurance, and even a moderate thickhidedness. Between one-third and one-fourth of cases of insanity suffered from organic brain disease. One of the most terrible but medically most interesting of the organic brain diseases, general paralysis, had lately become more prevalent among city populations. Last year the asylum had to deal with 65 cases, or 69 per 1000 residents—a quite unprecedented number. The number of cases of general paralysis in the Royal Edinburgh Asylum was thrice that in the whole of the Scottish asylums. It was doubtful whether insanity in general was on the increase. The death-rate had been higher during the past year owing to the large number of general paralytics and of other cases of organic brain disease admitted. Dr. Clouston concluded by referring to the proposal to establish a mental ward in the Royal Infirmary. During the past two years over 80 patients had been discharged cured from Morningside within six weeks of admission. All those might be reckoned among the incipient cases for whose benefit such a ward was intended. If established on right lines and properly worked this scheme would be most philanthropic and useful. He considered that it would be a wise and economical proceeding on the part of the parish council to approach the Royal Infirmary managers and to arrange, if possible, to pay a yearly sum for all patients admitted to such a ward in the infirmary.

### *Honorary Degrees of the University of Edinburgh.*

The Senatus Academicus of Edinburgh University have resolved to confer the honorary degree of Doctor of Laws at the April graduation ceremonial on the following:—The Right Hon. Herbert Henry Asquith, K.C.; Professor John Cleland, M.D., L R C S. Edin., LL.D., D.Sc, F.R.S., University of Glasgow; Professor Samuel Dill, M.A., Queen's College, Belfast; Mr. Austin Dobson; Professor James Alfred Ewing, B Sc, M.A., LL D, F.R.S., M.I C.E., University of Cambridge; Mr. Arthur William Rücker, M.A., D.Sc., F.R.S., Principal of the University of London; Mr. J. G. Schurman, M.A, D.Sc., President of Cornell University, U.S.A.; and Sir John Batty Tuke, M.P., M.D., F.R.C.P. Edin, F.R.S. Edin., Hon. D Sc.

### *Annual Dinner of the Royal Medical Society of Edinburgh.*

This dinner was held on March 4th. The guest of the evening was Dr. Patrick Manson, C.M.G. The chair was occupied by the senior president, Dr. A. M. Wood, while the other three presidents (Dr. W. E. Carnegie-Dickson, Dr. G. S. Carmichael, and Dr. J. G. McBride) acted as croupiers. There was a good attendance of members and guests.

### *A Grievance of the Resident Medical Officers at the Edinburgh Royal Infirmary.*

For a long time past there has been great dissatisfaction among the resident medical officers of the Royal Infirmary, Edinburgh, owing to the refusal of the managers to give them free personal laundry. This at first sight may appear a small matter, but the residents claim that in an institution where no salaries are paid they should at least be maintained at the hospital expense. Inquiry has shown that free laundry is provided for residents holding similar appointments in other Scottish and English hospitals. So far as can be ascertained the Edinburgh Royal Infirmary is the only large general hospital in the United Kingdom where such a privilege is not granted or an allowance made in lieu thereof. The managers have been petitioned repeatedly by the residents on this question but the request has always been refused. Considering that the managers have recently erected a new and very commodious laundry, and seeing that the extra expense would be trifling, the residents evidently feel deeply aggrieved that the re-statement of their grievance does not seem to be taken seriously by the board

### *Complete Excision of the Stomach for Cancer.*

The operation of excision of the whole stomach was performed by Mr. R. H. Parry at the Victoria Hospital, Glasgow, on Feb. 14th The case was one of extensive malignant disease and the patient has so far made a good recovery. It is believed to be the first time that the operation has been performed successfully in Scotland.

### *Aberdeen University.*

The summary of the needs of Aberdeen University as noted in the report to the executive committee of the Carnegie

Trust by the Aberdeen University Court is of considerable length and is subdivided into seven sections. The sums suggested under this heading are exclusive of any existing endowment for the purpose named, but are inclusive of annual grants from the general grants of the University (about £940) and from public bodies (about £350). A considerable part of the grants from public bodies is likely to be withdrawn. Under Section II. (Science and Medicine), Section V. (Research and Travelling Scholarships and Fellowships), and Section VI. (Other Purposes) the following items are specified, together with their annual cost: chair in Public Health, £950 to £1000; lectureships in Astronomy, Physiological and Pathological Chemistry, Medical and Surgical Electricity, Embryology, Art and Architecture, £1200 to £1500; lectureships in Mental Diseases, Ophthalmology, and Tropical Medicine, £750; research and travelling scholarships and fellowships in science, medicine, and arts, from £1500 to £2000; library, capital sum of £2000; laboratory equipment, capital sum of £10,000; upkeep of library, from £800 to £1000; and upkeep of laboratories and museums, from £1500 to £2000.—Lord Strathcona and Mount Royal, Lord Rector of the University, is to receive the freedom of the city of Aberdeen on April 9th. On the following day the graduation ceremony falls to be held in the Mitchell Hall of Marischal College.—A meeting of the Sites and Plans Committee was held on March 7th for the purpose of considering the report which the senatus had obtained as to the accommodation required by the different professors and lecturers in their various departments in the extended buildings at Marischal College. The provision desired for the physiology department consists of a large lecture-room and seven other rooms; for the department of medicine the requirements consist of a classroom, a museum and laboratory, a retiring room, and a dark room; for pathology a plea is put in for an animal room; and for materia medica an additional research room is desired, also the enlargement of the museum, an animal observation room, a curator's room, and a storeroom. The general requirements consist of an examination room and a considerable increase of library accommodation. The matter was ultimately referred to the architect and a sub-committee, to report to what extent and at what cost it is possible to provide the desired accommodation.

### *Aberdeen Dispensary.*

The annual meeting of the managers and subscribers of the Aberdeen Dispensary, Maternity Hospital, and Vaccine Institution, was held in the town hall on March 7th, Lord Provost Fleming presiding. The report showed that the total number of cases treated during the past year was 11,810.

March 11th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The College of Science in Dublin*

IN reply to the Member for South Belfast (Mr. W. Johnston, M.P.) the Chief Secretary said that it would be neither practicable nor desirable to remove the College of Science in Dublin to Belfast, the chief industrial centre in Ireland, as it was a national institution serving the needs of the whole country. The questions naturally arise, Why should scientific students in the north not have a college of science quite equal to that of Dublin, and why should the favours of the Crown in relation to the expenditure of public money be so largely confined to Dublin, a city with few industries and with a smaller population than Belfast, and in regard to the inhabitants of which Dr. W. K. Sullivan in his evidence before the Royal Commission on Technical Instruction, the report of which was issued in 1896, states, "The people of Dublin, who have been crying out for technical education lately, do not seem to know that they have had in their midst for the last 20 years one of the most complete polytechnic schools in Europe. If it has not done so much good as it might have done it is the fault of the people of Dublin." Under these circumstances the question is, Why should new buildings and an endowment of £8744 a year be given to Dublin and nothing to Belfast? But this is not all, for it appears that the museum in Dublin, handed over to the Agricultural and Technical Instruction Department by the Science and Art Department, South Kensington, with the College of Science, gets a yearly grant of £13,292, the Botanic Gardens receive an equal grant of £3842, while the Library receives £3732 a year. Dublin receives in connexion with the College of Science £29,680 per annum and Belfast, the great commercial centre of Ireland, not a penny. This great injustice to Ulster is felt to be a crying grievance and a campaign is being started so that the opportunities for higher scientific education shall not be confined to Dublin but shall be distributed in the provinces. What I say about Belfast applies equally to Cork. Why should those in search of higher scientific education in Cork be compelled to go to Dublin? The days of such absurd centralisation are surely now over. One of the Belfast newspapers asks "why it was that two eminent professors of the College of Science who offered to give evidence before the Royal Commission (on University Education) were not called," and hints that it was a desire to prevent disclosures about the causes of the backward condition of scientific and technical education in Ireland.

### *Royal College of Physicians of Ireland.*

The President and Fellows of the Royal College of Physicians of Ireland, at the monthly business meeting of the College held on March 7th, elected Dr. H. C. Drury as physician to Sir Patrick Dun's Hospital, in the place of the recently elected Professor of Institutes of Medicine, who has been exempted by the College from his hospital duties. It will be remembered that Dr. J. Mallett Purser, so widely known and appreciated by graduates in medicine of the University of Dublin during the last 20 years, was not only Professor of Institutes of Medicine but was also *ex officio* a physician to Sir Patrick Dun's Hospital. His office of professor at Trinity College was filled some weeks after his retirement. The post of physician to Sir Patrick Dun's Hospital has now been filled.

### *The Issue of Dispensary Tickets to Farmers.*

Dr. G. Evans, medical officer of the Plumbridge dispensary district, has written to the Strabane Board of Guardians stating that he had received a ticket for Poor-law medical relief for a farmer in good circumstances, with a £10 10*s.* Government valuation, and who, in his opinion, was able to pay a fee. The ticket was a 3*s.* one, and on it "5*s.*" was marked in and "3*s.*" was scored out. He thought that no guardian should tamper with tickets and he did not think that his fees should be fixed in such a way. He asked the guardians to cancel the ticket and to stop the practice. It was decided to cancel the ticket.

### *The Ulster Medical Society.*

The fifth annual meeting of the Ulster Medical Society was held in the Pathological Laboratory of Queen's College, Belfast, on March 6th, Professor W. Whitla, the President, being in the chair. The President showed a Heart with Mitral Stenosis with the history that a child with a well-marked presystolic murmur had, after running upstairs, been seized with sudden cardiac distress and the murmur previously present had disappeared and a mitral bruit took its place. The child subsequently died and the heart showed that the stenosed valve had ruptured and there were signs of recent valvulitis. Dr. A. Dempsey read notes of (1) a case of Acute Lymphatic Leukæmia; and (2) a case of Splenic Leucocythæmia. Dr. Thomas Houston read a paper on the Blood in Cases of Glandular Tumours, Dr. C. E. Shaw gave a lantern demonstration on the Structure of the Fœtal Larynx, and Dr. J. A. Craig gave a lantern demonstration on the Mastoid Antrum. The meeting then adjourned for a fortnight, only about one half of the work on the programme having been got through.

### *Royal Commission on University Education in Ireland.*

The Royal Commission on University Education in Ireland is to visit Belfast on April 2nd, when it is expected that there will be a great deal of evidence tendered. No subject has given rise to greater discussion than the vexed question of the settlement of university education in Ireland, and the two Blue-books already published, with evidence taken before the present commission, demonstrate the extraordinary differences of opinion which exist on the matter.

### *Tuberculosis and the Army.*

AT the sitting of Feb. 21st the Chamber of Deputies adopted some modifications of the law of 1889, which modifications will tend to give the revising councils the power of eliminating from the ranks of recruits those conscripts who show any tendency to tuberculosis. The council of revision may be asked to give a certificate drawing the attention of the military surgeon to the case of any conscript who at the drawing of the lots shall have made a declaration of illness. This certificate must be signed by a medical man, by the patient, and by the mayor of the commune. The prefect or the sub-prefect will hand over to every conscript who at the drawing of lots shall make a declaration of illness a form of certificate which runs thus:—

> I, the undersigned doctor of medicine of ... ....., certify that I have conscientiously examined number ......... in the cantonal lot-drawing of the department of ..... which deals with the recruiting of ...... ....., and I wish particularly to draw the attention of the revising military surgeon to the condition of the recruit's .......... (here name the organ affected).

This certificate when filled up will be delivered free of charge to the prefect of the department whose duty it is to present it for revision. Any conscript who is on the indigent list can be gratuitously examined by the medical officer of the *Assistance* of the commune. After revision such certificate must be given to the recruiting commandant, who will forward it to the regiment, so that the recruit will be kept under observation from the time at which he joins the colours. Volunteers will not be enrolled unless their physical condition answers all the required tests. In some regiments where the work is very hard, such as heavy cavalry or engineers, no volunteer will be enrolled under 19 years of age. Bacteriological laboratories will be established for the complete examination of the cases of recruits rejected by the council of revision, the staff of such laboratories being composed of experts nominated by the Minister of War. Those conscripts who after examination in the bacteriological laboratories are returned as unfit for service will not be drafted to a regiment but will have to present themselves before a discharge committee, one of which will sit at every recruiting centre. Every draft of conscripts on the day of departure for the regiment will attend at the recruiting centre and will have to undergo a further examination by the military surgeons. Those who do not come up to the physical standard will at once be sent before a discharge committee and will be discharged with certificate No. 2—*i.e.*, a certificate of temporary discharge.

### *Asphyxia in Nightmen.*

M. Hanriot has recently been giving the Society of Biology some information upon this subject. It is well known that nightmen who have to go down into cesspools are exposed to the danger of intoxication by the gases which collect in these receptacles. Chevreul considered that the toxic agent was sulphuretted hydrogen, but from experiments made by various observers it appears that this gas is only toxic when the proportion existing in the respired atmosphere is at least 5 per cent. M Hanriot has analysed the air in unventilated cesspools and has found that sulphuretted hydrogen exists only in the proportion of three parts per 10,000 On the other hand, the proportion of carbonic acid was 10 per cent., of oxygen 0 to 3 per cent., of nitrogen 45 per cent, of marsh gas 28 per cent. and of free hydrogen 9 per cent. The asphyxia to which nightmen are liable cannot therefore be due to sulphuretted hydrogen. M. Brouardel and M. Loye, who conducted, as experts, an inquiry into the deaths of nightmen who had perished from asphyxia, were surprised not to find at the post-mortem examination any of the usual appearances of poisoning by sulphuretted hydrogen. It appears, then, that death is due to want of oxygen, to the high proportion of carbonic acid, and possibly to the action of toxic volatile bases. It is possible for the contents of cesspools to give off sulphuretted hydrogen and if fæcal matter is treated with acids it gives off a large quantity of sulphuretted hydrogen and of carbonic acid But as a rule the contents of a cesspool are alkaline and contain some 2 or 3 per cent. of ammonia. Chemical disinfection is of no use; the only means of preventing such accidents is by the use of thorough ventilation.

### *The Death-rate in Guiana and New Caledonia.*

M. Kermorgen, Inspector-General of the Colonial Health Department, has laid before the Academy of Medicine some interesting statistics as to the death-rate in Guiana and New Caledonia The death-rate in the latter is far lower than in the former, and the Government, no longer acting from a somewhat misplaced sense of philanthropy, has ceased to send convicts to Noumea, one of the most beautiful of French colonies, but sends them again to Cayenne. However, despite the good climate, everything is not right in New Caledonia. Tuberculosis is very prevalent and leprosy is increasing. Of the latter there were 12 cases in 1895, while in 1900 there were 83 The general mortality from May 9th, 1864, to Dec 31st, 1895, was as follows. Of 21,630 convicts 7222 died. Of these, 5926 deaths were due to disease and 1296 to accident, a mortality of 277·6 per 1000. In Guiana the mortality from 1852 to 1895 was as follows. Of 31,903 convicts 15,189 died from disease and 789 from accident. The unhealthiness of Guiana is mainly due to malaria and yellow fever Various works to improve the sanitary conditions have been executed and the convicts are given minute directions as to the precautions which should be taken. But the sanitarian in Guiana has a special enemy to fight against—namely, the desire of the convicts to fall ill in order that they may go to hospital. Hence they will not use mosquito nets, or drink filtered water, or take quinine. That these precautions are protective is easily seen by looking at the condition of the warders who live under the same conditions as the convicts but who do take precautions. Among these the rate of mortality is extremely low.

### *Lactate of Mercury in Pharmacy.*

At the meeting of the Hospitals Medical Society held on Feb 28th M Gaucher said that he had long been on the look out for a mercurial preparation which should unite the four following advantages: (1) that of being an organic body; (2) easy to prepare and of definite composition; (3) of being unirritating and so capable of administration either by the mouth or by hypodermic injection; and (4) of containing such a proportion of mercury that a dose of one centigramme per diem should be enough. M. Gaucher, together with M. Lextrait, the pharmacist at the St. Antoine Hospital, and M. Caudillon, the *interne* in pharmacy at the same hospital, think that they have found a substance possessed of these desiderata in the neutral lactate of mercury. This salt contains less mercury than the perchloride does but more than the benzoate. It is easily prepared by dissolving red oxide of mercury in a 10 per cent solution of lactic acid. The acid must be pure. The dose is four *cuillerées à café* (from 40 to 50 minims) per diem of a 1 in 1000 solution if given in water or milk by the mouth, or one centigramme of a 1 per cent solution given by the hypodermic method.

March 11th.

# BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Trial and Acquittal of Professor Dührssen.*

THE body of one of the Berlin law courts recently presented somewhat the appearance of a medical congress owing to the number of medical men, especially gynæcologists, who were in attendance either as witnesses or spectators. The occasion was the trial of a charge made against Professor Dührssen, the well-known gynæcologist; and the case was a remarkable one, showing as it did that a surgeon must not only justify his actions before his own conscience but may also be called upon at any moment to justify them before a court of law. A woman had been sent to Professor Dührssen's private clinic to be operated on for retroflexion of the uterus, and he had been told by the medical man who sent her that she was very desirous of becoming a mother and that both she and her husband consented to the operation being performed. Professor Dührssen asked his assistant to make a preliminary examination and to take notes of the previous history of the case; being very much occupied he did not himself see the patient previously to operation until after the administration of chloroform He had intended to perform vaginofixation, an operation of his own devising, in which the uterus is fixed by sutures to the vagina. In the course of the operation he found that there were dense adhesions between the uterus and the rectum and that myomata were also present. He endeavoured to preserve the uterus, but the separation of the adhesions produced copious hæmorrhage which could not be stopped by the application of ligatures, so that he at last found it necessary to remove the whole of the uterus together with the growths. A fortnight after the operation the patient was able to return home feeling quite well. She was afterwards told what had been done and neither she nor her husband raised any objection. Six weeks later she was examined and found to be relatively well. Professor Dührssen was therefore not a little surprised when the husband brought an action against him claiming damages on the ground that the operation had been detrimental to the health of his (plaintiff's) wife, and had rendered her an invalid through the formation of a recto-vaginal fistula, so that she required nursing and special diet. This action would have been tried in a civil court, but without any obvious motive the husband withdrew it, substituting a charge of causing bodily injury by neglect (*fahrlassige Korperverletzung*). The case was accordingly taken up by the public prosecutor, and Professor Dührssen had to appear before a criminal court, where he gave an account of the circumstances, explaining that the removal of the uterus was unavoidable because the woman's life was endangered by the profuse hæmorrhage. The public prosecutor stated that before taking proceedings against the accused he had asked the opinion both of the provincial and of the central medical board (Provincial-Medicinal-Collegium and Wissenschaftliche Deputation für das Medicinalwesen) and that both of these bodies had expressed the opinion that the dangerous operation for retroflexion of the uterus was not indicated in the case of a patient who did not suffer locally and on account of her advanced age could not have been expected to become pregnant. Professor Dührssen replied that with regard to her age the woman had made a false statement to his assistant, for she had described herself as being only 40, whereas she was really 45 years of age Moreover, in his opinion the operation was not dangerous, for it had been performed by him 70 times without a fatal result. The evidence of the assistants and nurses belonging to the clinic confirmed Professor Dührssen's statement that at the commencement of the operation he intended to preserve the uterus, but ultimately found himself unable to do so on account of the profuse hæmorrhage. The patient herself declared that she would not have given her consent if she had been previously made aware that so dangerous an operation was to be performed; she said that she had been in good health before the operation, but was now an invalid; she was told in the clinic that the operation would remove an obstacle to pregnancy and in submitting to it she had no other inducement than this; she had understated her age as being 40 instead of 45 years from a natural unwillingness to admit that at the latter age she was still desirous of becoming a mother. Witnesses called by the defence then gave evidence to the effect that the woman's health had been unsatisfactory for some years, that she had already been in other clinics on account of uterine troubles, and that she had been heard to say that she wished to be relieved from all her pains as well as from the obstacle to pregnancy. Then followed the evidence of the medical experts, of whom a great many were called both by the defence and by the prosecution, not only from Berlin but also from other cities, and even some foreigners. Professor Ruge of the provincial medical board was called by the prosecution and said that it was the opinion of the board that an operation so dangerous was not indicated in the case of a patient who suffered comparatively little and on account of her advanced age was very unlikely to become pregnant; at any rate the previous consent of the patient ought to have been obtained, and it was the duty of the surgeon to explain to her beforehand that in the course of the operation conditions might perhaps be encountered which would necessitate the removal of the uterus. Professor Fritsch of Bonn, for the defence, said that it was quite within Professor Duhrssen's competence to direct his assistant to attend to matters which had to be discussed with the patient and that it was in no way obligatory on him to undertake this himself. Professor Fritsch considered [illegible] there was a collective responsibility of the surgeon [illegible] the assistant; it was allowable for a surgeon [illegible] on being told by his assistant that [illegible] had been duly explained to the patient [illegible] en her consent; the question whether an operation was justifiable or not was a matter of conscience and of experience and could not be determined by the evidence of witnesses or by judicial methods of arriving at a decision; provided always—as he believed was the case—that the patient's consent had been given and that there was a reasonable probability of the operation being successful Professor Dührssen had acted justifiably. The public prosecutor then asked for a conviction on the charge of causing bodily injury by neglect, but in view of the good work that had been done by Professor Dührssen and the fact that his motives were quite disinterested a fine of only 300 marks (£15) was proposed. Counsel for the defence entered a plea of not guilty, explaining to the court that the patient's consent to the operation was proved by the fact that she had understated her age in order to induce Professor Dührssen to operate and that afterwards it had to be left to him to do what was necessary in order to save her life. The court, after a short deliberation, found the accused not guilty. The presiding judge stated that the patient's evidence was not reliable, that the court was persuaded that she had consented to the operation, and that Professor Dührssen could not be found guilty of neglect, as asserted by the public prosecutor, merely because the previous history of the case had been taken by his assistant and not by himself. In the opinion of the court Professor Dührssen had not failed in his duty as a conscientious surgeon. The case has naturally been much discussed by the general public as well as in medical circles. The *Berliner Klinische Wochenschrift* suggests that the shorthand-writer's notes of the proceedings and the substance of the finding of the court should be published, so that the medical profession may have an authentic report of a case of such fundamental importance, and the Berlin Medical Chamber will be asked to discuss the advisability of a reform of the criminal law in respect to medical practice, for the Duhrssen case shows that in the present state of the law a surgeon has no security against malevolent prosecution.

### *Health of Professor Virchow.*

According to current reports Professor Virchow's health is now quite satisfactory. The fracture of the femur has united and he gets up every day, but, considering his age the probability of a resumption of his lectures is not great.

### *The Plague.*

BUBONIC plague has broken out again in Sydney. On Jan. 15th it was reported that rats were dying in a block of houses at Rushcutter's Bay and shortly afterwards three occupants of the premises were found to be suffering from bubonic plague and were sent to the Coast Hospital. The premises were thoroughly disinfected and their contents destroyed by fire. The surrounding locality was found to be in a very insanitary condition and several houses have been destroyed. A fresh case has also occurred in Brisbane, of a virulent form. The other states remain free from plague, but rat-destroying is still vigorously prosecuted

### *Infectious Diseases in Victoria.*

The returns of infectious diseases for the fortnight ending Jan. 4th presented to the Board of Public Health of Victoria showed a marked increase in the number of cases of typhoid fever and diphtheria—viz., 105 cases and eight deaths had occurred during that period in the whole state from typhoid fever, as against 58 cases and two deaths for the corresponding period last year. Within the metropolitan area the numbers were 46 cases and six deaths, as against 26 cases and one death for the fortnight ended Jan. 2nd. The diphtheria returns in the whole state showed 65 cases and four deaths as against 28 cases and two deaths in the corresponding period last year. In the metropolitan area there had been 14 cases and one death, as against 16 cases and one death last year.

(FROM OUR OWN CORRESPONDENT.)

### *Tuberculosis and the Army.*

AT the sitting of Feb. 21st the Chamber of Deputies adopted some modifications of the law of 1889, which modifications will tend to give the revising councils the power of eliminating from the ranks of recruits those conscripts who show any tendency to tuberculosis. The council of revision may be asked to give a certificate drawing the attention of the military surgeon to the case of any conscript who at the drawing of the lots shall have made a declaration of illness. This certificate must be signed by a medical man, by the patient, and by the mayor of the commune. The prefect or the sub-prefect will hand over to every conscript who at the drawing of lots shall make a declaration of illness a form of certificate which runs thus :—

> I, the undersigned doctor of medicine of ......., certify that I have conscientiously examined number ........... in the cantonal lot-drawing of the department of .... which deals with the recruiting of ........, and I wish particularly to draw the attention of the revising military surgeon to the condition of the recruit's ........ (here name the organ affected).

This certificate when filled up will be delivered free of charge to the prefect of the department whose duty it is to present it for revision. Any conscript who is on the indigent list can be gratuitously examined by the medical officer of the *Assistance* of the commune. After revision such certificate must be given to the recruiting commandant, who will forward it to the regiment, so that the recruit will be kept under observation from the time at which he joins the colours. Volunteers will not be enrolled unless their physical condition answers all the required tests. In some regiments where the work is very hard, such as heavy cavalry or engineers, no volunteer will be enrolled under 19 years of age. Bacteriological laboratories will be established for the complete examination of the cases of recruits rejected by the council of revision, the staff of such laboratories being composed of experts nominated by the Minister of War. Those conscripts who after examination in the bacteriological laboratories are returned as unfit for service will not be drafted to a regiment but will have to present themselves before a discharge committee, one of which will sit at every recruiting centre. Every draft of conscripts on the day of departure for the regiment will attend at the recruiting centre and will have to undergo a further examination by the military surgeons. Those who do not come up to the physical standard will at once be sent before a discharge committee and will be discharged with certificate No. 2—i.e., a certificate of temporary discharge.

### *Asphyxia in Nightmen.*

M. Hanriot has recently been giving the Society of Biology some information upon this subject It is well known that nightmen who have to go down into cesspools are exposed to the danger of intoxication by the gases which collect in these receptacles. Chevreuil considered that the toxic agent was sulphuretted hydrogen, but from experiments made by various observers it appears that this gas is only toxic when the proportion existing in the respired atmosphere is at least 5 per cent. M. Hanriot has analysed the air in unventilated cesspools and has found that sulphuretted hydrogen exists only in the proportion of three parts per 10,000. On the other hand, the proportion of carbonic acid was 10 per cent., of oxygen 0 to 3 per cent, of nitrogen 45 per cent., of marsh gas 28 per cent. and of free hydrogen 9 per cent. The asphyxia to which nightmen are liable cannot therefore be due to sulphuretted hydrogen. M. Brouardel and M. Loye, who conducted, as experts, an inquiry into the deaths of nightmen who had perished from asphyxia, were surprised not to find at the post-mortem examination any of the usual appearances of poisoning by sulphuretted hydrogen. It appears, then, that death is due to want of oxygen, to the high proportion of carbonic acid, and possibly to the action of toxic volatile bases. It is possible for the contents of cesspools to give off sulphuretted hydrogen and if fæcal matter is treated with acids it gives off a large quantity of sulphuretted hydrogen and of carbonic acid. But as a rule the contents of a cesspool are alkaline and contain some 2 or 3 per cent. of ammonia. Chemical disinfection is of no use ; the only means of preventing such accidents is by the use of thorough ventilation.

### *The Death-rate in Guiana and New Caledonia.*

M. Kermorgen, Inspector-General of the Colonial Health Department, has laid before the Academy of Medicine some interesting statistics as to the death-rate in Guiana and New Caledonia. The death-rate in the latter is far lower than in the former, and the Government, no longer acting from a somewhat misplaced sense of philanthropy, has ceased to send convicts to Noumea, one of the most beautiful of French colonies, but sends them again to Cayenne. However, despite the good climate, everything is not right in New Caledonia. Tuberculosis is very prevalent and leprosy is increasing. Of the latter there were 12 cases in 1895, while in 1900 there were 83. The general mortality from May 9th, 1864, to Dec 31st, 1895, was as follows. Of 21,630 convicts 7222 died Of these, 5926 deaths were due to disease and 1296 to accident, a mortality of 277 6 per 1000. In Guiana the mortality from 1852 to 1895 was as follows. Of 31,903 convicts 15,189 died from disease and 789 from accident. The unhealthiness of Guiana is mainly due to malaria and yellow fever Various works to improve the sanitary conditions have been executed and the convicts are given minute directions as to the precautions which should be taken. But the sanitarian in Guiana has a special enemy to fight against—namely, the desire of the convicts to fall ill in order that they may go to hospital. Hence they will not use mosquito nets, or drink filtered water, or take quinine. That these precautions are protective is easily seen by looking at the condition of the warders who live under the same conditions as the convicts but who do take precautions. Among these the rate of mortality is extremely low.

### *Lactate of Mercury in Pharmacy.*

At the meeting of the Hospitals Medical Society held on Feb 28th M. Gaucher said that he had long been on the look out for a mercurial preparation which should unite the four following advantages : (1) that of being an organic body ; (2) easy to prepare and of definite composition ; (3) of being unirritating and so capable of administration either by the mouth or by hypodermic injection ; and (4) of containing such a proportion of mercury that a dose of one centigramme per diem should be enough. M. Gaucher, together with M. Lextrait, the pharmacist at the St. Antoine Hospital, and M. Caudillon, the *interne* in pharmacy at the same hospital, think that they have found a substance possessed of these desiderata in the neutral lactate of mercury. This salt contains less mercury than the perchloride does but more than the benzoate. It is easily prepared by dissolving red oxide of mercury in a 10 per cent. solution of lactic acid. The acid must be pure. The dose is four *cuillerées à café* (from 40 to 50 minims) per diem of a 1 in 1000 solution if given in water or milk by the mouth, or one centigramme of a 1 per cent solution given by the hypodermic method.

March 11th.

# BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Trial and Acquittal of Professor Dührssen.*

THE body of one of the Berlin law courts recently presented somewhat the appearance of a medical congress owing to the number of medical men, especially gynæcologists, who were in attendance either as witnesses or spectators The occasion was the trial of a charge made against Professor Dührssen, the well-known gynæcologist ; and the case was a remarkable one, showing as it did that a surgeon must not only justify his actions before his own conscience but may also be called upon at any moment to justify them before a court of law. A woman had been sent to Professor Dührssen's private clinic to be operated on for retroflexion of the uterus, and he had been told by the medical man who sent her that she was very desirous of becoming a mother and that both she and her husband consented to the operation being performed. Professor Dührssen asked his assistant to make a preliminary examination and to take notes of the previous history of the case ; being very much occupied he did not himself see the patient previously to operation until after the administration of chloroform He had intended to perform vaginofixation, an operation of his own devising, in which the uterus is fixed by sutures to the vagina. the course of the operation he found that t profession, one of whom, after an honourable record in the British navy, still occupies a high position as a practitioner in Monte Video, and the other after a distinguished career as a student in the late Queen's University in Ireland died from phthisis a few years ago in Texas. The late Dr. Mullin himself was an *alumnus* of the Queen's University, Ireland, having graduated as M.D., M Ch., and L.M. in 1880. Previously to his medical career he had sojourned for some time in the Southern States of America, and was an intimate friend of General Beauregard and other well-known Confederate leaders. Throughout his career as a student Dr. Mullin was distinguished for his remarkable assiduity and the whole-hearted zeal with which he devoted himself to the mastery of his profession. After a few years of preliminary study in Queen's College, Galway, he went to Dublin and studied medicine at the Meath Hospital under the late Dr. Foot and surgery at the Richmond Hospital under the late Sir William Stokes. By both these distinguished teachers he was held in the highest personal esteem. He graduated as M.D., M.Ch., and L.M. in 1880 and after some years' practice in Dublin finally settled down in Newport, Mon., to the career of a general practitioner. His career in Newport extended over some 10 years, and although he went there as a perfect stranger, by his genial manner and kindly disposition he soon succeeded in winning hosts of friends, and by his skill, attention, and unflagging energy he gathered together a very large practice. During his 10 years' residence in the town of his adoption he probably had not more than 10 days' holiday. This unremitting labour could have but one result, and the inevitable breakdown occurred without any premonitory symptoms when he dropped dead on Feb. 17th. The cause of death was heart failure. His funeral was probably one of the most striking spectacles that ever occurred in the annals of Newport. From his house to the cemetery, a route over a mile in length, all traffic was suspended and all that distance was completely blocked by the multitude who followed his hearse. It was quite touching to see how many were in tears and the poor especially manifested the deepest grief. But the townspeople were not satisfied with even this tribute of affection to his memory, as they started a shilling subscription to erect a memorial that would keep his name ever green amongst them.

## JOHN LUMSDEN PROPERT, M.B. LOND., M.R.C.S. ENG.

We much regret to announce the death of Dr. John Lumsden Propert, which occurred on Friday, March 7th, at his house in Gloucester-place, from pneumonia after a brief illness. Dr. Propert was born 67 years ago and was the son of the founder of the Royal Medical Benevolent College at Epsom. He received his medical education at King's College Hospital, where he filled the resident appointments, and at the age of 22 years he graduated in medicine at London University, having previously taken the diploma of the Royal College of Surgeons of England. On leaving the hospital he joined his father in practice, and by his energy, ability, and assiduous attention to his patients, became a highly-successful general practitioner. His quiet, dignified manner, unfailing tact, and knowledge made his patients at once feel that they had placed themselves under a man whose opinion would not be given lightly and would be valuable when expressed.

Dr. Propert, himself a good etcher, was widely known in artistic circles as a connoisseur in many departments of art, and his house in Gloucester-place was full of beautiful specimens of china, pottery, and jewelled work. He was generally credited with being the originator of the revival of interest in miniature-painting which has lately taken place in England, and he possessed at one time a very fine collection of miniatures At the exhibition of portrait miniatures at the Burlington Fine Arts Club he compiled the illustrated catalogue, which he afterwards enlarged into a book upon British Miniatures that is familiar to all collectors.

There was a full congregation at the funeral service, held at St. Mary's, Bryanston-square, on Tuesday last, for Dr. Propert had a large circle of private and professional friends. Among those present may be mentioned Sir Thomas Smith, Mr. Christopher Heath, Dr. T. Buzzard, Dr. G. H Savage, Dr. Whipham, and Dr. Frederick Taylor. Many members of the council of the Royal Medical Benevolent College were lso pr although Dr. Propert had not been able to give the amount of time to the working details of the college that had been given by his father he never ceased, as a member of the council, to take an active interest in the institution, which was represented at his funeral by Dr C. Holman (treasurer), Sir R. Douglas Powell, Dr. M. Baines, Mr Stamford Felce, Mr. Reginald Harrison, Mr. H. W. Kiallmark, Mr. C. L. Smiles, Dr. F. Taylor, Colonel Gordon Watson, Rev. T. N. Hart Smith (head-master), and Mr. J. B. Lamb (secretary). The Rev. Russell Wakefield, rector of St. Mary's, Bryanston-square, gave a touching address on the relations of medical men to the public, and concluded by asking the prayers of the congregation for "John Propert's son, now taking up in the third generation the work of the father and grandfather."

# Medical News.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentlemen having passed the necessary examinations and conformed to the by-laws have been admitted Members of the College and have received their diplomas:—

James Weeden Woodhams Adamson, St. George's Hospital; Frederick Eustace Anley, Charing Cross Hospital; Henry Lawrence Atkinson, Yorkshire College and General Infirmary, Leeds, and St. Mary's Hospital, Stanley Bean Atkinson, B.Sc. Lond., LL.M. and M.A. Camb., St. Bartholomew's Hospital; Austin Lewis Badcock, Charing-cross Hospital; Edward Walter Bain, London Hospital; Hugh Barber, Owens College and Royal Infirmary, Manchester, and Guys's Hospital; Wilfrid Boothby Blandy, Charing-cross Hospital; John Crosthwaite Bridge, Middlesex Hospital; Harrie Spence David Browne, B.A. Camb., Cambridge University and St. Thomas's Hospital; William Walker Browne and Joseph Barnes Burt, University College Hospital; Alexander Cameron, Middlesex Hospital; George Fernandez Mitchell Clarke, L.S.A. Lond., Charing Cross Hospital; Ernest Langsford Clay, Mason College, Queen's and General Hospitals, Birmingham; Joseph Basil Cook, Owens College and Royal Infirmary, Manchester, and St. Bartholomew's Hospital; Ernest Alfred Cox, King's College Hospital; William Thomson Crawford, University College Hospital; Richard Ingram Cuming, St. Thomas's Hospital; Henry Tregellas Doble, St. Mary's Hospital; Robert Valentine Dolbey, and Reginald Anthony Eastmond, London Hospital; Harold Augustus Easton, St. Thomas's Hospital; Charles John Ernest Edmonds, L S.A. Lond., St. Thomas's Hospital; Frederick Kincaid Etlinger, University College, London, and Newcastle Royal Infirmary; Douglas Edward Finlay, St. Mary's Hospital; Edward Fow Fisher, London Hospital; Edward Cecil Foster, University College Hospital; George Denne Franklin, B.A. Camb., Cambridge University and St. Thomas's Hospital; John Gay French, St. Mary's Hospital; Charles Herbert Gask and Arthur William Gater, Guy's Hospital; George Frederick Gill, Otago University and St. Bartholomew's Hospital; Ian Canute Gordon Glassford, Melbourne and Edinburgh Universities; Bertram Winter Gonin, St. Mary's Hospital; Eric Walton Grogono, London Hospital; William Rhodes Harrison, St. Mary's Hospital; Percival George Harvey, St. Bartholomew's Hospital; Somerville Hastings, Middlesex Hospital; Walter Turner Haydon, St. Thomas's Hospital; Frederick Lewis Henderson, Cambridge University and Middlesex Hospital; George Sullivan Clifford Hayes and Hugh Arthur Higgens, Guy's Hospital; Walter Henry Philip Hill, M.D., C.M. McGill, McGill University, Montreal; Andrew Ferguson Horn, University College Hospital; Charles Reginald Howard, B.A. Camb., Cambridge University and Guy's Hospital; Leslie Edward Hughes, St. Bartholomew's Hospital; Edwin Hyde, Cambridge University and St. George's Hospital; Francis Willan Jackson, St. Bartholomew's Hospital; Luis Ricardo Jimenez, Guy's Hospital; Hugh Nevill Keeling, Yorkshire College and General Infirmary, Leeds, and St. Mary's Hospital; Thomas Thelwell Kelly, Alfred Dudley Eskell Kennard, and William Perceval Ker, Guy's Hospital; Horace Harvard Kiddle, St. Thomas's Hospital; Henry Ardagh Kingsmill, M.D. West Univ., Western University, Ontario, Edinburgh, and Middlesex Hospital; Frederick Samuel Langmead, St. Mary's Hospital; Albert Penard Laycock, Cambridge University and London Hospital; Alfred Newman Leathem, Charing-cross Hospital; Napoleon Leonard, St. Bartholomew's Hospital; John Woodruff Lewellyn, University College, Cardiff, and St. Bartholomew's Hospital; Archibald Malcolm Macintosh, St. Mary's Hospital; Matthew Robert Cecil MacWatters, King's College Hospital; Frank Derecourt Martyn, Westminster Hospital; Hugh Giffen McKinney, Henry Norman Marrett, Herbert Michael Henry Melhuish, and Guy Witton Miller, St. Bartholomew's Hospital; Oswald Mills, St. Thomas's Hospital; William John Morrish, St. Mary's Hospital; Cyril Raymond Moss, M.A. Oxford, Oxford University and University College and Royal Infirmary, Liverpool, Sydney Gwenffrwd Mostyn, M.A. Oxford, St. Bartholomew's Hospital; Norman Howard Mummery, University College, London; Lorimer Gifford Nash, Guy's Hospital; Harold Rundle FitzNattle, University College Hospital; Richard Arthur Needham, B.Sc., M B., Ch.B. Vict., Owens College and Royal Infirmary, Manchester; William Nicholson, L.D.S. Eng., Owens College and Royal Infirmary, Manchester; Paul Norman Blake Odgers, B.A. Oxford, Oxford University and Guy's Hospital; John Norman Parrott, St. Mary's Hospital; Victor Stanley Partridge, L.S A. Lond., Westminster and Charing-cross Hospitals; Nathaniel Richard Phillips, University College, Cardiff, and University College Hospital; Charles Arthur Gayer Phipps, Owens College and Royal Infirmary, Manchester, and London Hospital; James Farquharson Powell, St. George's Hospital; John Philip also reported against any extension, as the site was unsuitable. The Board has passed the following resolution :—

> That the Minister be informed that, in the opinion of this board, land in two or more suitable localities in the State should be set apart for the reception and treatment of persons affected with tuberculosis, and that the land should be of such area as to afford the most ample opportunities and meet all possible requirements for exercise and recreation of all persons therein received and treated.

The Minister of Health has approved of the proposal and placed it before the Cabinet. The Board regards the treatment of consumption as a national question and considers *the present sanatorium at Echuca to be unsatisfactory as to* position and extent.

### *Infectious Diseases Hospital, Melbourne.*

As has been previously stated, the Infectious Diseases Hospital, Melbourne (for which the public subscribed, as a memorial of Queen Victoria's Jubilee, the sum of £19,000), has never been completed, about £4000 more being required to make it available for patients. The Victorian Government has now decided to grant this amount, as it regards the hospital as a national institution. The committee will *accordingly get the necessary work—completing the laundry,* furnishing, &c.—completed as soon as possible. The difficulty of maintaining the institution, however, still remains.

### *Ptomaine Poisoning.*

Forty people at Darlington, Sydney, have been affected with an illness resembling cholera, violent abdominal pains, retching, and diarrhœa. In some cases the whole family was affected, in others only single individuals. In every case the sufferers had partaken of corned beef purchased at the same shop, and the cases are regarded as due to ptomaine poisoning. The police seized the remaining portions of beef at the shop and had them destroyed.

### *Intercolonial Medical Congress.*

The arrangements for the sixth session of the Intercolonial Medical Congress, to be held in Hobart on Feb. 17th, are fairly complete and the meeting promises to be very successful. Mr G. H. Butler has been nominated as president in place of the late Dr. Bright. The attendance promises to be large and the contributions to the sections numerous. A special discussion is to be held on Cancer.

### *Professor of Pathology, Sydney University.*

At its last monthly meeting the Senate of the Sydney University elected Dr. David Arthur Welsh, M.A., B.Sc, M.D. Edin., to the new chair of Pathology. Dr. Welsh was a distinguished student at Edinburgh University and recently pathologist to the Royal Infirmary. He has also been senior assistant to the professor of pathology and lecturer in pathological bacteriology. It is somewhat remarkable that so many of the teachers in the Sydney medical school are Edinburgh men.

### *The Medical Act, New South Wales.*

A Bill to amend the present Medical Act of New South Wales has been drafted and read for the first time in the Legislative Assembly. If passed it would bring about the state of things existing before the present Act was passed.

### *Committee versus Staff of Women's Hospital.*

A remarkable position has developed at the Women's Hospital, Melbourne. On Dec. 25th, 1901, a patient was admitted to the midwifery side of the hospital and developed septicæmia, from which she died on Jan. 3rd. She was isolated and the ward in which she had been was disinfected. Between Jan. 10th and 17th five midwifery patients developed high temperatures and were isolated. They did not develop any further septic symptoms and have recovered. Another patient was said to be suffering from "sapræmia" These facts were reported to the committee who appointed a subcommittee to investigate the circumstances. This was done. The resident medical staff gave it as their opinion that there was no danger of an outbreak of septicæmia in the institution, but the opinion of the honorary medical staff does not appear to have been definitely obtained. The chairman of the midwifery staff, Mr. G. Cuscaden, who reported the occurrences originally, seems to have been very undecided in his views and in some way or other caused the committee to think that there was danger and that the hospital should be closed. At all events, the sub-committee reported to the committee that no fresh cases should be admitted and that arrangements should be made to attend to patients in various nursing homes in the neighbourhood The committee gave orders that this should be done. The resident staff thereupon refused to carry out the instructions and said that they would admit and treat cases. The superintendent and secretary also refused to carry out the instructions of the committee and lock the gates of the hospital The committee then dismissed the superintendent and informed the resident medical officers that their services would be dispensed with at the end of a month. The honorary staff met to consider the position and reported that in their opinion there was no necessity to close the hospital. In the meantime cases had been admitted by the resident medical officers. Finally, the committee, in deference to the views of the honorary staff, decided to remove the patients from the main wards to others and thoroughly to disinfect the main wards, and when that is done to receive patients in the ordinary way Naturally the episode has excited much interest in Melbourne and caused much correspondence in the newspapers The whole difficulty arose from a lay committee interfering in a question which should have been decided by the medical staff.

### *Deniliquin Hospital.*

At the annual meeting of the Deniliquin Hospital (New South Wales) it was stated by the committee that plans for a new hospital had been prepared to replace the present building erected 45 years ago. The money required had already been given by Mr. Landale.

### *Obituary.*

Dr. Michael J. Clune died on Jan. 3rd at North Sydney at the age of 54 years. He was a native of Sydney and took his B.A degree at Sydney University in 1863. Then he went to Dublin University where he had a brilliant career as a student. He returned to Sydney in 1872 and commenced practice in College-street. He was physician to St. Vincent's Hospital for 20 years. He was the first medical man in Australia to adopt Sayre's method of treating spinal caries. The first time small-pox occurred in Sydney Dr. Clune attended the first patient and reported its nature He was sent with his patient to the quarantine station and on his release he advocated and secured many useful and necessary reforms in the management of the station.—Another well-known Sydney practitioner has passed away in the person of Dr. C. F. Eichler who was probably the oldest medical man in Sydney where he had practised for half a century. He came to Sydney in charge of a German immigrant ship. For many years he was honorary visiting surgeon to the Sydney Hospital. He founded the German Club in Sydney and was one of the oldest members of the Royal Society of New South Wales. He was an enthusiast in rose culture, having over 1000 varieties on his estate at Marrickville. He was a well read man and a great linguist, speaking eight languages, but always most modest and unassuming. He died on Jan 10th at the age of 80 years.—Another very old practitioner in Victoria died recently, Dr. D. J. Williams He was *nearly 84 years old and had* been long in bad health. When a young man he went to Russia and was medical officer of the Czar's yacht *Victoria.* He arrived in Melbourne in 1852 in charge of immigrants and was soon appointed medical officer at Queenscliff. He was transferred to Ballarat in 1854 as medical officer to the police and coroner, and was there during the Eureka riots He then returned to Queenscliff, where he entered upon private practice He was the oldest justice of the peace in the State

Feb. 4th.

## Obituary.

### JOHN FRANCIS LANGAN MULLIN, M.D., M CH. R.U I

"IN Dr Mullin's death the poor have lost a good friend and Newport has lost a good citizen." With these words the coroner for Newport (Mon.) wound up the inquest on the late Dr. John Francis Langan Mullin and words more appropriate to the occasion were never uttered. The deceased gentleman was a native of Ireland, having been born in the historic town of Drogheda some 52 years ago He was not the only member of his family who was connected with medicine, for he had two brothers in the

Mr. Grant Lawson replied: Some lymph was obtained by the Local Government Board from Cologne in December, 1900, and it has passed through a series of five calves in succession. The resulting lymph was that used in the case of Mr. Essex. The original lymph and that derived from it have been used in the vaccination of 264 calves and no complaints have been received of ill-effects from the use of the resulting lymph in any other case, although it has been used for the vaccination of a large number of persons. I cannot give precise information as to the derivation of the particular lymph obtained from Cologne, but as a rule the stock there is renewed by inoculation of the calf with human vaccine lymph.

### *Increased Comforts at the Royal Victoria Hospital, Netley.*

Captain Norton asked the Secretary of State for War whether he could say what steps, if any, had been taken to increase the comfort in the wards of the Royal Victoria Hospital at Netley by the addition of chairs for invalid soldiers in lieu of the forms heretofore in use.—Mr. Brodrick replied that 600 Windsor chairs with cushions had been issued to Netley for use in wards, &c. Further, comfortable easy-chairs had been provided for the wards by Her Majesty the Queen out of a sum of money which she had at her disposal.

### *Vaccination Prosecutions.*

On the motion of Mr. Channing a Bill was introduced to provide that no prosecution under the Vaccination Acts shall be commenced without the authority of the guardians.

## Monday, March 10th.

### *Enteric Fever among the Troops in South Africa.*

Sir Walter Foster asked the Secretary of State for War whether he had received the report of the commission of experts appointed in August, 1900, to inquire into the causation, pathology, and modes of prevention (more particularly as affecting armies in the field) of dysentery and its connexion, if any, with enteric fever; and, if not, if he would call for the report, and lay it upon the table of the House for the use of Members.—Mr. Brodrick: The report is now complete but has not yet been printed.—Sir Walter Foster asked the Secretary of State for War whether he could state the number of cases of, and the number of deaths from, enteric fever during the months of December and January last.—Mr. Brodrick: The approximate figures for December are: admissions, 1507; deaths, 224. The figures for January are not yet complete.

### *Vaccination and Small-pox in Bethnal Green.*

Sir Mancherjee Bhownaggree asked the President of the Local Government Board if he could state how many cases of small-pox had occurred or been reported from the borough of Bethnal Green since the beginning of the year; and what proportion of persons so afflicted was found to be unvaccinated.—Mr. Long replied: I am informed that 136 persons were reported to the medical officer of health for the borough of Bethnal Green during January and February last as suffering from small-pox, but 13 of these were found not to be cases of that disease. The particulars as to vaccination are as follows:—31 were unvaccinated, of whom 12 died; four were vaccinated children under 13 years, of whom none died; 76 were persons above 13 years, who were stated to have been vaccinated in infancy, of whom seven died. The medical officer had no information as to vaccination as regards the remaining 12 cases.

## Tuesday, March 11th.

### *Medical Inspection for the Imperial Yeomanry.*

Dr. Farquharson asked the Secretary of State for War whether the enlistment of the Imperial Yeomanry was carried out by officers of the Army Medical Department or by local private practitioners necessarily unfamiliar with the details of the standard required for regulars; whether he was aware that in the printed instructions issued there was a paragraph which stated that there was no need to reject men for minor defects and deformities as the standard need not be so high as for regulars; and whether these instructions were seen and sanctioned by the Director-General of the Army Medical Department before being issued.—Mr. Brodrick replied: In consequence of the absence of a large proportion of the officers of the Royal Army Medical Corps in South Africa the bulk of the men were examined by local practitioners. Instructions were issued that the conditions required of a recruit enlisting for the full term of service in the army might be modified. Instructions were issued to the effect that if the recruit was free from organic disease or other serious defect likely to prevent him from work during the continuance of the campaign he might be accepted. I have not been able to trace whether the late Director-General of the Army Medical Department was consulted, but the question was rather military than medical.

### *Medical Establishments of the Navy.*

While the House was in Committee of Supply a vote of £246,500 was taken for the medical establishments of the navy. Mr. Arnold-Forster, Financial Secretary of the Admiralty, stated in the course of the debate that the principle of attaching hospital ships to the squadrons in time of peace was not to be extended, but provision was being made for rapidly equipping hospital ships in time of war. The whole fittings for several such ships had been provided and arrangements had been made for medical officers to accompany them. Medical stores had also been provided. The policy of having hospital ships had been deliberately adopted after a great deal of consideration. The medical, and, he believed, also the naval, view was that the conditions of a modern ironclad were so unfavourable to the nursing of the sick and wounded that it was most desirable to have some ship accessible in case of war to which the men might be removed as soon as possible in order that they might receive proper treatment and nursing.—Mr. Whitley pointed out that while there was practically no addition to the number of medical officers the salaries to be paid showed an increase in the aggregate of £4800, and he asked for an explanation.—Mr. Arnold-Forster explained that medical officers in the army were about to receive higher emoluments, and it had been thought right to offer corresponding inducements to medical men to join the service of the navy. The additions to the pay were, however, very slight.—Sir Henry Campbell-Bannerman said that he would like this matter further explained, because the House had been led to understand that the medical service of the navy was in a perfectly satisfactory position.—Mr. Arnold-Forster, speaking again, said that owing to the number of candidates for the army not being very large it had been found necessary to increase the emoluments of the service. In the case of the navy the number of candidates had been just sufficient but not more than sufficient. It was found, however, that when the emoluments of the officers in the army were increased there was an immediate check in the applicants for the navy, and it was decided that this could not be allowed to continue. After consultation with the War Office it was arranged that the emoluments of the navy should be the same as those of the army.

---

## MIDWIVES BILL.

### Proceedings before the Grand Committee.

The Grand Committee of the House of Commons on Law met on Tuesday, March 11th, with Sir James Fergusson in the chair, and began the consideration of the Midwives Bill.

The first clause, setting out the short title of the measure, was postponed.

Clause 2 of the Bill deals with certification. In its original form it proposed in the first section that "from and after the first day of January, 1905, no woman shall be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words) or any name, title, addition, or description implying that she is certified under this Act or is recognised by law as a midwife unless she be certified under this Act."

Sir Walter Foster moved to insert in this section after the first "midwife" the words "or nurse midwife." He did so, he said, in order to raise the general question of what was intended to be done by this legislation. There had been a great deal of talk about Mrs. Gamp and Mrs. Harris, but these ladies, famous in English literature, were not touched by the Bill. Now, if they wanted to do this work thoroughly they ought to include all classes of women who attended childbirth, including Mrs. Gamp and Mrs. Harris, who were the chief source of danger. Of 10 women who attended midwifery cases one was a technically qualified person and held some sort of certificate after a certain amount of training, and the other nine were really monthly nurses and it was these nine who in the opinion of medical men were responsible for the mischief that occurred.

Mr. Heywood Johnstone asked the committee not to accept this amendment because the Bill proposed to deal only with midwives and not with "nurse midwives," whatever that term might mean. It might be a very desirable thing in the interests of the public health that every person who attended women in childbirth should be registered and qualified and supervised, but this could not be done at the present moment. The condition of kindred professions did not encourage such an experiment and they could only proceed by steps in a matter of this kind. They had been something like 10 years, if not more, in getting as far as they had, and he asked the committee seriously to consider this point and not to take a step which would overload the Bill and prevent its passage. The promoters had designedly made it a somewhat modest Bill because they knew that only by so doing they would have a chance of seeing the Bill passed. If they accepted this amendment it would be the first step towards destroying and wrecking the Bill.

Sir Barrington Simeon said that he would like to know whether this was a Bill to protect the title of "midwife" or a Bill to protect parturient women.

Mr. Heywood Johnstone said that it was a Bill to protect parturient women in the same sense that persons desiring the services of a medical man were protected by being able to distinguish between qualified and unqualified medical men.

On a division the amendment was rejected by 21 votes to 7.

Mr. Parker Smith moved to insert words to secure that the uncertified woman shall not use a title implying that she is "a person specially qualified to practise midwifery." These words, he said, were taken from the Dentists Act. The Bill did not propose to impose a penalty upon any woman who practised for gain, but it did propose to defend the public by letting it know that the woman who used the title "midwife" might be relied on to do her work efficiently. He considered that no woman should be entitled to call herself an "obstetric nurse" or a "nurse midwife" or anything else of that kind unless she were certified under the Act.

Mr. Heywood Johnstone said that his only objection to the proposed words was that he thought they would render the clause cumbrous and were unnecessary; though they appeared in the Dentists Act it was rather difficult to know what meaning they would carry. Supposing that there was a criminal prosecution it would be a very difficult thing for anyone to say that the person against whom proceedings were taken had used some name, title, or description, implying that she was a person specially qualified to practise midwifery. Members of the committee must bear in mind that they were dealing here with a penal clause and that it was desirable that the words used should be few and simple and leave as little room as possible for mistake.

Mr. Ambrose approved the amendment as strengthening and improving the clause.

The amendment was carried by 19 votes against 12 and the words were inserted in the clause.

The committee then took up the consideration of the second section of the clause; "Any woman who, after the first day of January, 1905, not being certified under this Act, shall take or use the name of midwife, or any other such name, title, addition, or description as aforesaid, shall be liable on summary conviction to a fine not exceeding £5."

Mr. Griffith-Boscawen moved to insert after the first "shall" the words "habitually and for gain attend women in childbirth or shall." He understood the object of the promoters of the Bill to be to put an end to the frightful amount of preventable suffering and disease which occurred owing to the attendance of perfectly ignorant women; and in order that this terrible evil might be thoroughly dealt with it was necessary that these ignorant women should be prohibited from [illegible] altogether. As the Bill stood there was nothing in it to prevent these ignorant women from practising or to secure their proper training. The Bill merely granted legal certificates to what he might call the better class of midwives and allowed all these ignorant, dirty, and dangerous women to continue in future as they did at the present moment. Instead of striking a blow at the people who really did harm the Bill left them alone. He thought that the committee ought to aim at making a thorough and complete measure, one that would deal with

UNIVERSITY OF CAMBRIDGE —At a congregation on March 8th the following medical degrees were conferred —

*M B and B C* —W F Tucker Gonville and Caius
*M B only* —G W Deeping Trinity

The Balfour Studentship is awarded to Mr J S Budgett of Trinity, and the Allen Scholarship to Mr F N Hales of Trinity

VACCINATION OF TRAMPS —The Liskeard (Cornwall) Board of Guardians recently passed a resolution directing that all tramps should obtain a certificate from the medical officer of health stating that they were free from any infectious disease before they were admitted to the workhouse The medical officer of health consequently informed the guardians that such work was outside his duties and that his fee for each inspection would be half a crown At the meeting of the guardians held on March 1st it was decided to rescind the resolution

THE BRISTOL GENERAL HOSPITAL —At the half-yearly meeting of the governors of this institution held on March 10th it was announced that the scholarships were awarded as follows Clarke's Surgical Scholarship, £15 to Mr A. R Short, Sanders Scholarships, £22 10s, to Mr J E Sparks, and £11 5s to Mr C Corfield, Lady Haberfield prize £29 9s 8d between Mr A. J M Wright and Mr J F Blackett Martyn Memorial Scholarship £10 each to Mr J E Sparks and Mr C Corfield, Henry Marshall prize, £11 Mr A R Short

DONATIONS AND BEQUESTS TO HOSPITALS —By the will of Mr Robert Rolle McQuater the sum of £150 has been bequeathed to each of the following institutions —the Adelaide Hospital in Dublin, Sir Patrick Dun's Hospital and St Mark's Ophthalmic and Aural Hospital —The Royal London Ophthalmic Hospital, City road E C has received a donation of 30 guineas and the North Eastern Hospital for Children Hackney, a donation of £10 10s from the Leathersellers Company —By the will of Mr James Alexander Molleson of Edinburgh £1000 have been left to the Victoria Hospital for Consumption and a similar amount to the Children's Hospital

PRUDENTIAL ASSURANCE COMPANY, LIMITED —The fifty third annual report of this company for the year ending Dec 31st 1901 shows its continued prosperity In the ordinary branch the number of policies issued during the year was 76 831 assuring the sum of £7 575 835 and producing a new annual premium income of £399 776 The premiums received during the year were £3,489 955 being an increase of £167 613 over the year 1900 The claims of the year amounted to £1 563 775 The number of deaths was 6723 and 6105 endowment assurances matured The number of policies in force at the end of the year was 651 553 In the industrial branch the premiums received during the year were £5,529 461, being an increase of £81 704 The claims of the year amounted to £2,104 939 The number of deaths was 211 670, and 2227 endowment assurances matured The number of free policies granted during the year to those policy holders of five years standing who desired to discontinue their payments was 74 798 the number in force being 771,279 The number of free policies which became claims during the year was 17,880 The total number of policies in force at the end of the year was 14 334 820 their average duration exceeded nine and a half years The assets of the company, in both branches, as shown in the balance sheet were £43 292,026 being an increase of £3 396 698 over those of 1900

THE INCORPORATED SOCIETY OF TRAINED MASSEUSES —The members of the Incorporated Society of Trained Masseuses held their annual meeting on Feb 14th at the Trained Nurses Club, 12, Buckingham street Strand There was a good attendance The meeting was an animated one and a very general interest was evinced in the business of the evening The honorary secretary is Miss Grant Trained Nurses Club 12 Buckingham street, Strand

EXETER DISPENSARY —The annual meeting of the managers of this institution was held on Feb 22nd under the presidency of Colonel Hardinge The medical report stated that 5638 patients had been treated during 1901 compared with 5571 in the previous year The financial statement showed that the income amounted to £1836 the expenditure being £1918 The deficit was met by drawing on the capital of the institution, which at the end of the year amounted to £17 301

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD —The eighty eighth annual report of this hospital, which has just been presented to the annual court of governors states that during the last year 709 patients have been under treatment in the wards of the hospital, and there has been an attendance of 26 884 persons in the out-patient department The festival dinner, which was held at the Hotel Metropole on May 6th 1901, for the purpose of raising £10 000 to purchase a freehold site to build and to furnish a nurses home and to carry on the work of the hospital brought in receipts amounting to £5858 3s 9d This amount included new annual subscriptions amounting to £68 16s and was £1227 12s 7d in excess of the amount collected at the previous festival dinner in 1898 and is the largest amount ever collected for the charity at a festival dinner The total income for the year amounted to £9656 15s 9d, as against £7365 8s 5d in 1900 The donations show an increase of £2543 17s, but a loss of £85 in annual subscriptions is very much to be regretted The total expenditure amounted to £10 486 3s 8d, and is £2784 2s 8d in excess of that of 1900 This increase is largely due to the payment of £2000 for the freehold site of the proposed Nurses Home The hospital was thoroughly cleaned and repainted throughout during the summer, and a number of much needed repairs to the roof and gutterings were effected, necessitating an outlay of £490

## HOUSE OF COMMONS

### THURSDAY MARCH 6TH

*Preservatives and Colouring Matters in Food*

SIR SEYMOUR KING asked the President of the Local Government Board whether he has decided to take steps by the introduction of a Bill or otherwise of giving effect at an early date to the recommendations of the report of the Departmental Committee which inquired into the use of Preservatives and Colouring matters in the preservation and colouring of food and whether he is aware of the opinion [illegible] sanitary authorities in England in favour of those recommendations —Mr GRANT LAWSON replied The report referred to is under consideration and I cannot at present make any statement as to the course to be taken in regard to it With respect to the last part of the question the Local Government Board has received only one or two communications from sanitary authorities on the subject

### FRIDAY MARCH 7TH

*[illegible]*

Mr CORRIE GRANT asked the President of the Local Government Board whether [illegible] the case of [illegible] as far back as [illegible] [illegible] after [illegible]

Mr. Schwann took the view that it would be doing the Obstetrical Society of London an injustice if it were not recognised in the manner proposed in the Bill and asserted that the tests applied by the society to its candidates were often more severe than those applied to medical men in connexion with this particular work.

Mr. Griffith-Boscawen said that the whole object of this legislation seemed to be to glorify this society. He admitted that it had done good work, but here they were setting up a new board and the first thing they proposed to do was to tie its hands by saying that it must accept the certificates of this particular society.

Sir Barrington Simeon thought that the better course would be to make no distinctions of any kind, but to leave the matter with the Central Midwives Board.

Mr. Ambrose took the view that if any institutions were to be mentioned they should all be mentioned.

Sir Michael Foster pointed out that this arrangement would only last for two years and that thereafter the Central Midwives Board would be free to establish its own standard.

Sir Walter Foster said that the first two years were all important, because they would give the character to the whole subsequent proceedings.

Mr. John Dillon spoke of the clause as a pure advertisement of the Obstetrical Society of London.

On a division the amendment moved by Sir John Tuke was rejected by 18 votes against nine.

Sir John Tuke then moved to extend the special recognition to the following institutions—viz., the Queen Charlotte Hospital, London, the Maternity Hospitals of Manchester, Birmingham, Liverpool, Edinburgh, and Glasgow, and the Rotunda and Coombe Hospitals, Dublin.

Sir Walter Foster, in supporting this amendment, said that nothing did more to lower the medical profession than the two years of grace allowed after the passing of the Medical Act of 1858. Shiploads of gentlemen went from London and other places up to certain universities in the north and came back full-blown doctors of medicine and there were hundreds put upon the Medical Register in that way.

Sir John Tuke said that he must put in an absolute denial to that statement.

Sir Walter Foster said that his hon. friend represented one of these universities and was bound to stand up for it, but the fact remained.

Sir John Tuke insisted that the statement was absolutely unfounded.

Sir Walter Foster said that he knew what he was talking about. He was invited himself to go to one or two of these places. The doors of these institutions were opened and a large amount of money went into their coffers. In the present case he would wish to have no names inserted in the Bill at all.

Sir John Tuke said that he must be allowed to say that as regards the universities of Scotland the statement of his hon. friend was entirely and absolutely without foundation.

The amendment was rejected by 17 votes against eight.

The committee then adjourned until Friday, March 14th.

## ROYAL COMMISSION ON ARSENICAL POISONING.

A meeting of this Commission, for the examination of witnesses, was held on March 7th, in the Westminster Palace Hotel, Lord Kelvin, chairman of the Commission, presiding.

Dr. Ernest S. Reynolds (Manchester) who gave evidence last year, presented himself for further examination. In reply to the Chairman he said that a special look-out had been kept by himself and his assistants at the Manchester Workhouse Infirmary, the Manchester Royal Infirmary, and in his private practice for any symptoms which might have been caused by arsenic occurring in food or drink. They found that the symptoms had practically all disappeared. The keratosis, the arsenical neuritis, and the pigmentation had quite disappeared and the cases of herpes had very much diminished. Even the pigmentation which had been ascribed for years to the irritation of vermin in the pauper class had very markedly lessened in frequency. Up to the end of September, 1901, a few cases showing arsenical symptoms presented themselves at Crumpsall, but in all cases except two it was found that they had suffered already during the winter 1900–1901 and had not entirely recovered. The two exceptions were women who said that they had only recently—about May—become affected. In each of these cases Dr. J. Dixon Mann found that the hair contained a considerable quantity of arsenic. The beer which one of the women had consumed was found to contain one-hundredth of a grain of arsenic per gallon of beer. He could not give the actual amount of arsenic found in the hair. He had, however, the analyses of some hair which Mr. Scudder, the chemist in Manchester, had given him, which showed minute traces of arsenic, something like 0·003 per cent.; this was in the hair of a healthy person who was not known to have taken arsenic in any way. The idea that Gautier wished to make out was that arsenic was an essential ingredient in the thyroid gland, but knowing what they did now about the prevalence of arsenic in all sorts of things he (Dr. Reynolds) thought that it was quite likely that it was introduced from an outside source. Dr. Reynolds did not think that arsenic was an essential ingredient of hair, because in analysis they had had many blank results. At Crumpsall, from Nov. 30th, 1900, to July 20th, 1901, they had had 30 deaths—17 women and 13 men. Of these 10 men l four women were found to be suffering from rapid consumption. hese figures did not include the cases of patients who had died before e cause of the outbreak was known.

By Sir William Church: Since 1901 his experience in Manchester of euritis and other conditions attributed to arsenic had approximated to the experiences of the other large towns in this country. During the last nine months, in hospital and in private practice, he had seen a considerable number of very heavy drinkers, but only two cases of peripheral neuritis. These cases were in private practice and the symptoms were those of neuritis. One case was that of a cab-driver who drank at least a bottle of whisky a day and the other was that of a woman who did the same. In the case of the cab-driver there were pains in the limbs and some loss of power, but there was no wasting and there were no other signs at all of any arsenical poisoning and he did not think that the man took beer. The woman was bed-ridden and certainly took no beer. The symptoms were coming on rather fast. There was some wasting, there was distinct loss of power, and there were marked pains in the limbs; but again there was not a single sign of any other arsenical symptom. These were the only two cases which he had been able to pick out in which beer-drinking could be excluded and in which there were signs of peripheral neuritis. In beer-drinkers pure and simple there was now no peripheral neuritis in Manchester. It was extremely probable that arsenic might remain locked up in the thyroid gland for a long time. He knew that Dr. Dixon Mann had been examining thyroid gland and that he had not found arsenic in it, and he (Dr. Reynolds) thought that the experiments of Gautier should be taken with some reserve.

By Dr. Whitelegge: He thought that a great deal of the pigmentation which was thought to be due to vermin was actually due to arsenic. He would expect to find pigmentation from arsenic alone and he did not think that alcohol added to the tendency.

By Sir William Church: If he found arsenic either in the hair or the urine he should look for an arsenical causation.

By the Chairman: Very many of the arsenical patients who had died had died from phthisis, and in most of the cases of cirrhosis of the liver with ascites post-mortem examination had shown that there was also tuberculous peritonitis. There were still two or three old arsenical cases suffering from paralysis at the workhouse infirmary; they were recovering very slowly. During the last seven months he had been watching most carefully for cases of so-called true "alcoholic" neuritis occurring in pure spirit-drinkers, and although there had been but little or any decrease in alcoholic consumption in the district during this period and he had seen very many heavy drinkers, yet alcoholic neuritis (whether in spirit-, beer-, or mixed-drinkers) seemed to have disappeared from the district, which was formerly noted for the prevalence of the condition. These observations were confirmed by his colleagues and professional friends. Curiously enough, there had been also an enormous decrease, almost to *nil*, of cases of so-called "alcoholic" cardiac muscular dilatation, with a disappearance of the marked œdema of the legs seen in the arsenical cases. From his clinical observations during the last 20 years he was driven to the conclusion that the disappearance during the last seven months of so many symptoms which were formerly described as being due to alcohol could only be explained by the elimination of arsenic from alcoholic beverages, and as a corollary that arsenic had been present in alcoholic beverages (*to an extent dangerous to a few drinkers specially susceptible*) for many years and possibly from a source entirely independent of contaminated glucose. In September, 1901, Major Ronald Ross asked him to see a case of supposed beri-beri. The patient, who had been brought from the West Coast of Africa, was an American lady, the wife of a missionary, and she was a total abstainer. She had well-marked neuritis exactly similar to that occurring in arsenical poisoning; there was a history of a "rash" and there was very slight punctiform pigmentation. She had been living principally on tinned Californian fruit. Her hair was examined by Dr. Dixon Mann who reported to him that it contained "not a mere trace but considerable quantities of arsenic." The Californian fruit had been examined by Mr. Scudder and had been found to be practically free from arsenic and therefore it could be set aside so far as Mr. Scudder's examination was concerned. He would suggest that those tinned foods should be further examined for the presence of arsenic. The idea that arsenic might be the cause of some cases of so-called beri-beri, as suggested by Major Ross and himself some time ago, was now gaining ground in the tropics and evidence was forthcoming to show how easily arsenical poisoning might occur in tropical districts. Dr. Dixon Mann had examined specimens of hair in 24 cases of patients who were suffering from beri-beri which had been sent to him from various parts of the world; 18 of these specimens were found to be free from arsenic and six of them to contain the drug, but he (Dr. Reynolds) did not know in what quantity. Dr. Reynolds had recently received samples of the hair of four beri-beri patients in the hospital ship at Cardiff who had come from Rangoon. These he sent to Dr. Dixon Mann who found that two of them yielded no arsenic, one an appreciable amount of arsenic, and one a trace of arsenic. Although he did not think that the arsenical origin of beri-beri was proved, still the matter was worthy of further consideration, especially when the dreadful character of the disease and its great prevalence were thought of. The lady whose case he had mentioned said that she had not used any arsenical hairwash and that so far as she knew she had not taken any drug containing arsenic. After consulting with Dr. Dixon Mann he was of opinion that the *absence* of arsenic in the hair in a suspected case of arsenical poisoning did not prove that the case was not arsenical. The test for arsenic in hair required the greatest skill and experience for its performance, and results given must be examined critically unless the analyst was of high-standing and well-known ability. Some little time ago, at the request of Dr. Hodgson, he visited St. Luke's Hospital, Halifax. He saw there four suspected cases of arsenical poisoning. One case, that of a man, seemed somewhat doubtful clinically, but in this case Dr. Hodgson chemically proved the presence of arsenic in the body. The other three cases, two men and a woman, were very well-marked cases of arsenical poisoning, the clinical appearances being severe and most typical. Moreover, in his opinion, they had been poisoned with arsenic probably within three months of his visit. If he were asked to explain this outbreak at Halifax he should say that the beer and the malt ought to be examined.

The other witnesses examined were Mr. Arthur Angell, public analyst, Southampton, and his son, Mr. Arthur French Angell, who gave evidence as to a series of experiments carried out by them to determine whether or not plants were capable of taking up arsenic from soils manured with arsenical phosphates. They explained that in speaking of arsenic they meant arsenious oxide, the white arsenic of commerce. Several samples of the ordinary superphosphate manures of commerce were obtained from three large manufacturers and were tested for arsenic. Arsenic was found in every instance—22 in all. The quantity found was generally about 0·03 per cent. by weight on the whole manure. An ordinary superphosphate of lime was mixed with ½ per cent. of arsenic, this being a proportion of arsenic about 17 times greater than the quantity usually present in commercial phosphates an admitted evil. They ought to insert the provision that was in the Bill of 1900. He could not understand why it had been omitted. They ere told that a certain Government office objected. He had very reat belief in Government offices but, after all, they could not be allowed to dictate the legislation of the country, and if the House of Commons thought that in order to deal thoroughly with a matter certain enactments were necessary it was for the House to pass those enactments and for the Government office to see that they were properly carried out. They had been told that this was contrary to the precedent of the Medical Act, the Dentists Act, and other Acts but he did not think that the cases were analogous. There was an evil here which required a very stringent enactment. They had been told by Sir Michael Foster that this legal certificate would be enough in itself to prevent people from employing women who were not certified; that they would always resort to the certified woman. He could not believe this. On the contrary, he believed that poor people would continue to resort to the lower class of midwife because of the lowness of her fees.

Mr T. P. O'CONNOR said that he thought it was a defect in the law that the public were not more protected from quacks. The law was that anyone could go and consult a quack. His first objection, therefore, was that they were introducing with regard to a class of inferior medical practitioners (if he might so lescribe midwives) a principle which had not yet been established n the law with regard to a large superior, and more responsible body f practitioners—namely, physicians and surgeons. Another point as that if this Bill were passed the new class of certified midwives hich it would bring into existence would not become a numerous ss, for some considerable time at any rate, in the small towns and villages. If this amendment were passed it would deprive many places of all the aid to which they had been accustomed or nearly the whole of it. Therefore he thought that the amendment was premature.

Sir JOHN BATTY TUKE said that he could not see the force of the last argument used by Mr O'Connor because according to the Bill any midwife of reputable character now in practice could claim to be certified during the first two years from the date of the Act coming into operation. Surely therefore there would be sufficient midwives to fill up any gaps created by this legislation. The penal provision was in the Bill of 1900, and he could see no good reason for its omission from the present Bill.

Mr HEYWOOD JOHNSTONE said that the mover of the amendment knew perfectly well that the acceptance of these words meant the ruin of the Bill. He knew perfectly well that Governments even in these days of large majorities had some little control over the shaping of private Members' Bills. But apart from that, an objection to this amendment was that it was contrary to Parliamentary procedure and practice in all kindred matters. The Medical Act of 1858 did not make unqualified practice penal; it simply imposed a penalty upon persons who professed to be qualified when they were not qualified just in the same way as this Bill proposed to impose a penalty upon women who professed to be qualified midwives when they were not qualified. From the very passing of the Medical Act of 1858 the General Medical Council and other medical authorities had tried their best to make unqualified practice of any sort penal and he found that so lately as last month one of the leading medical papers said that the omission to penalise unqualified practice was a great defect in the Medical Acts. This therefore was the thin end of the wedge and if the committee were to allow it to be inserted they would very soon find Parliament asked to amend the Medical Acts so as to render all unqualified practice penal. The amendment was not only contrary to the Medical Act, but it was also contrary to the Dentists Act 1878, and to the Veterinary Surgeons Act 1891. He might also say that these words which were in the Bill of two years ago raised very great doubts as to the position of the person generally known as the friendly neighbour. Two years ago the promoters of the Bill sought in every possible way to frame words which would satisfy those Members who were desirous that women helping their neighbours in this time of trouble should be protected from all danger of penalty or interference but they could not frame any form of words which were satisfactory to those who wished to protect the interests of these women. If the words proposed in the amendment were put in they would, no doubt, interfere very seriously with the help of the friendly neighbour for let it be remembered that in a matter of this kind poor people were easily frightened and if they thought that there was any risk whatever they would not examine minutely the words of the Act of Parliament but would simply run off frightened. The fate of the Bill practically depended upon the fate of this amendment and he asked the committee to reject the amendment.

Sir WALTER FOSTER said that he had long been connected with the General Medical Council and he had never known it to take any steps to put down unqualified practice in the sense referred to by the hon. Member. All that the General Medical Council had done had been to try to protect the registered practitioner and occasionally to institute prosecutions against persons who used titles indicating that they were registered. He could not think that the analogy between the midwives proposed to be registered under this Bill and the medical profession was a correct one. The medical pro[illegible] were the vast majority of the people engaged in the practic[illegible] edicine surgery, and midwifery but the women here were only [illegible] all section probably about one tenth of those engaged in the pr[illegible] f midwifery. They were taking pains to protect a certain sm[illegible] limited class of certified midwives whereas the whole class [illegible] ly nurses who did an infinitely greater amount of harm were left [illegible] le. He submitted that in such a matter there should be a penal cl[illegible]. As to what would happen in country districts, the women now [illegible] in practice would come in and be registered the moment th[illegible] Bill was passed and the Central Midwives Board was constitut[illegible].

Mr SCHWANN insisted that if the proposed words were introduced they would raise a legion of opponents to the Bill.

Sir MICHAEL FOSTER said that the operation of the measure could only be a matter of opinion and in spite of the strong assertions to the contrary he still believed that its operation would eventually very largely diminish almost to extinction, the class of women whom they all desired to be extinguished. He had practised the art of midwifery for some six years in country districts, and he believed that without calling into operation any penal clause the Bill would produce the desired result.

Sir FRANCIS POWELL said that since the second reading of the Bill he had gone into this matter very carefully and he had come to the conclusion that it would be safer on the whole to do without a penal provision.

On a division the amendment was rejected by 25 votes against eight.

Mr AMBROSE moved to insert these words: "Or any woman who being licensed under this Act shall employ as a substitute at any childbirth any person not licensed under this Act shall be liable on summary conviction to a fine not exceeding £5, provided always that nothing in this Act shall apply to any person or persons attending a woman during labour in a case of emergency until the services of a person licensed under this Act or of a registered medical practitioner, are available." The hon. Member denied that he had any wish to wreck the Bill; he merely wished to make it as perfect as possible.

Mr HEYWOOD JOHNSTONE pointed out that there was already in the Bill a provision that no woman certified under the Act should employ an uncertified person as her substitute.

The amendment was negatived without a division.

Sir JOHN TUKE moved to insert a section to the effect that "no woman shall be entitled after the first day of January, 1906, to recover any fee or charge for attendance as a midwife unless she is certified under this Act." He argued that it was only a matter of justice to the certified midwife that she should have this security for her fees.

Mr PARKER SMITH hoped that the committee would accept this section which he said was thoroughly in accordance with the principles of the Medical Acts. It was one of the inducements offered to medical practitioners to get registered that registration enabled them to sue for fees in a court of law and he thought that this inducement should be offered to midwives.

Mr HEYWOOD JOHNSTONE said that he must ask the committee to decide this question for the promoters of the Bill. There was much to be said on both sides. Personally he should feel considerable difficulty in resisting the amendment because he felt considerable sympathy with it but on the other hand it must be borne in mind that they were disentitling a woman to recover fees for doing what was a perfectly legal act.

Mr GRIFFITH BOSCAWEN spoke in support of the amendment as calculated to improve the legal position of the certified midwife.

The amendment was carried by 21 against 10 votes and the words proposed by Sir John Tuke were accordingly inserted in the Bill.

Mr T. P. O'CONNOR moved to insert these words: "No woman certified under this Act shall represent that she is to be regarded as an independent practitioner of midwifery." The main opposition of the medical profession to this Bill was that they were creating a class of midwives who would usurp not to the disadvantage of the profession but to that of parturient women, the position of the obstetric physician. For himself, he regarded this as a serious danger. The midwife should be entitled to act as a midwife only in a perfectly easy natural normal state of things, and he did not think that too many provisions could be inserted in the Bill to enforce this upon the mind of midwives.

Mr COHEN criticised the proposed words as ambiguous.

Mr HEYWOOD JOHNSTONE said that he did not know what this amendment was aimed at or what it would effect.

Sir WALTER FOSTER said that the object of the amendment was to bring home to midwives that they must not regard themselves as independent practitioners of midwifery and that when anything went wrong with a case it became their duty to send for a medical practitioner. In the interests of the smooth working of the Bill he was inclined to support the amendment.

Mr EMMOTT said that while he was in sympathy with the object of the amendment he did not think that the words proposed were of any use.

Sir WALTER FOSTER: What the medical profession means by an independent practitioner of midwifery is a person, man or woman, who is qualified to practise midwifery in all its branches.

Mr EMMOTT: Quite so, but would the judges mean that?

Sir WALTER FOSTER: Nobody can tell what the judges will do with Acts of Parliament but these words have been arrived at after some deliberation and I believe that they are proposed in perfectly good faith.

After some further discussion Mr O'CONNOR withdrew the amendment.

The committee then proceeded to the consideration of Clause 3—viz.: "Any woman who within two years from the date of this Act coming into operation claims to be certified under this Act shall be so certified provided she holds a certificate in midwifery from the Royal College of Physicians of Ireland or from the Obstetrical Society of London or such other certificate as may be approved by the Central Midwives Board or produces evidence satisfactory to the board that at the passing of this Act she has been in *bonâ fide* practice as a midwife and that she bears a good character."

Mr T. P. O'CONNOR took exception to the two bodies named being distinguished by this special treatment and suggested that the whole responsibility as to the acceptance of certificates should be left with the Central Midwives Board.

Sir JOHN TUKE moved to strike out of the clause the reference to the Royal College of Physicians of Ireland and the Obstetrical Society of London. He thought that not only was it invidious to make any destinction in this connexion but it was inferentially setting up a standard for the Central Midwives Board.

Mr HEYWOOD JOHNSTONE gave an account of the work done by the Obstetrical Society of London and said that the question was whether in this Bill there should be some recognition of that work. The society, he said, had been doing the very work which in future would be done by the Central Midwives Board and again and again it had been openly stated that when a duly qualified examining board had been called into existence [illegible] as he hoped one would be by this Bill, the functions of the society as far as the examination of midwives was concerned would cease. At the present moment there were 6527 women on the register of the society who he thought would make an admirable [illegible] under the new system. In these circumstances he asked the committee to recognise the society in the manner suggested.

Sir WALTER FOSTER said that it was the first time that he had known of an Act of Parliament being used to give a testimonial to a private society. He objected to the Obstetrical Society of London being given special advantages over other societies engaged in the same work. All these 6527 women would come upon the register by virtue of the decision of the Central Midwives Board and therefore they would suffer no detriment.

Hodson, V. S., B.A., M.B., B.Ch. Oxon., has been appointed Senior Obstetric Physician to St. Thomas's Hospital.

Hudson, A. C., M.A., M.B., B.C. Cantab., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Jones, B.S., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant House Surgeon to St. Thomas's Hospital.

Martin, John Middleton, B.A., M.B., B.C., D.P.H. Cantab., has been appointed Medical Officer of Health for the Stroud Urban District Council, vice T. Partridge, M.R.C.P. Irel., M.R.C.S., L.S.A., resigned.

## Births, Marriages, and Deaths.

### BIRTHS.

Farthing.—On March 4th, at Dartford, the wife of T. Farthing, M. Edin., of a son.

Ferguson.—On March 5th, at Canfield-gardens, South Hampstead, t wife of Arnold Ferguson, F.R.C.S. Edin., of a daughter.

Gedge.—On March 4th, at Pewsey, Wilts, the wife of Arthur Sydn Gedge, M.R.C.S., L.R.C.P. Lond., of a daughter.

Thomson.—On the 10th inst., at Bridge House, Retford, Notts, the w of Dr. George Thomson, of a son.

Tyson.—On March 3rd, at Folkestone, the wife of W. J. Tyson, M. Durh., F.R.C.P. Lond., F.R.C.S. Eng., of a daughter.

Young.—On March 3rd, at Sydney, N.S.W., the wife of H. Tay Young, M.D. Glasg., of a son.

### MARRIAGE.

Longhurst—Phillipson.—On March 8th, at St. Alban's Churc Teddington, Percy A. Longhurst, M.R.C.S., L.R.C.P. Lond., Naida Eveleigh Phillipson, eldest daughter of the late N. Phillipson.

### DEATHS.

Dudley.—On March 7th, William Lewis Dudley, M.D. St. An F.R.C.S. Eng., in his 82nd year.

Nightingall.—On Feb. 26th, at 83, London-road, St. Leonards on Se Robert Salisbury Nightingall, M.D. St. Andrews, M.R.C.S. En L.S.A., in his 86th year. Interred at Hollington.

Sedgefield.—On Feb. 8th, at Sanawar, Punjab, India, Lieutena Colonel Arthur Robert Wyatt Sedgefield, I.M.S., aged 47 years.

Turnbull.—On March 7th, at Cleveland-gardens, Surgeon Maj Francis Turnbull, I.M.S. (retired), aged 82.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

Half the manure was applied at the time of sowing and half when the young plants were well above ground care being taken on each application to avoid actual contact between the manure and seed or plant It was determined by experiment that the arsenic when mixed with superphosphate was readily soluble in cold water The method adopted for the testing for, and estimation of, arsenic was Hehner's modification of Marsh's process The results of their experiments which had been carried as far as one season permitted went to show that the roots of plants were capable of taking up arsenic from soils manured with arseniated phosphates From the roots the arsenic could rise in the fibro-vascular bundles by a process of suction and capillarity and might be present in measurable quantities in the early stages of succulent growths Arsenic was found in rhubarb petioles and leaf blades and in the young leaves or grass of rye and buckwheat and in the stems and leaves and green pods of broad beans In no instance was the faintest trace of arsenic present in the fruit or seed of any plant It thus appeared that in those parts of the plants which were remote from the influences of mere mechanical forces and where vital or physiological energies predominated a selective power was brought to bear, and arsenic even if present was rejected No arsenic was present in the green, unripe, nor in the fully ripe seeds of buckwheat barley wheat oats maize, rye nor in the fruits of tomatoes and cucumbers nor in the whole plants of lettuce and cabbage nor in carrots and mangold They had satisfied themselves that the culture of all the plants was carried on with due care to prevent the adherence of the arseniated phosphate to any part of the plants above ground

The elder girl became very pale and sat with her head outside the omnibus to avoid being sick. On reaching home—a few minutes' walk from the omnibus—I found that the baby was not well. He refused all food and was listless. All night he was feverish and restless and cried as though in pain. In the morning we found the right side of his face swollen and the gums of the right side of the upper jaw inflamed. This was followed by ulceration of the gums and the complaint affected in succession the left side of the upper jaw and then both sides of the lower jaw. He was ill for 10 days, feverish, and very restless, and in a good deal of pain, taking very little nourishment. The ulceration was accompanied by fœtor, his breath smelling like the lamp of phosphoretted hydrogen. The fever and ulceration were followed by enlargement of the submaxillary and sublingual glands and a fall in which the back of a chair struck the chin was followed by an abscess. I am, Sirs, yours faithfully,

(Mrs.) L. H. ANDREW BIRD, L.R.C.P. Irel.

De Beauvoir-road, N., March 3rd, 1902.

## THE BAEL TREATMENT OF DYSENTERY.

*To the Editors of* THE LANCET.

SIRS,—Seeing your remarks on my letter which you were so good as to insert in your issue of Jan. 4th last, Messrs. Bathgate of Calcutta, who prepare the dietetic bael to which I referred, write and refer me to the opinions expressed in Watt's "Dictionary of the Economic Products of India," vol. i., pp. 117, et seq., which greatly predominate in favour of the dried bael fruit as a remedy for dysentery and diarrhœa in comparison with the ripe fruit, the latter being chiefly looked upon as a laxative merely. I certainly agree with you nevertheless in the great value of the fresh fruit in cases of dysentery. I have no experience of Squire and Sons' preparation from the fresh fruit which, from what you say, must be excellent, but I have known Bathgate's preparation, their dietetic bael, which from their letter I presume they prepare from dried unripe fruit, to work marvellous cures. So the inference is that preparations such as Squire's and Bathgate's from either the ripe or unripe fruit are alike most excellent remedies. Would it not be well to have a good supply of such valuable remedies for dysentery kept in our field hospitals with sanction given for the most liberal use of the same, whereby many of our soldiers' valuable lives might be saved.—I am, Sirs, yours faithfully,

Southbourne, Feb. 26th, 1902. J. E. B. PARSONS.

## OVERPAID INCOME-TAX.

THE Income-tax Adjustment Agency, Limited, writes to remind our readers "that no claim for repayment of tax deducted from rents, dividends, annuities, &c., in respect of the year ended April 5th, 1899, will be allowed unless the same be lodged before April 5th next. Where the income has been received and tax paid a claim can now be made for four years." The Agency states that "with few exceptions, all persons whose incomes do not exceed £700 are entitled to exemptions or abatements; even when the income is said to be 'free of income-tax,' and on an income not exceeding £400 the amount repayable might amount to £42." All claims should be made with the least possible delay, as the time allowed for making some of them is strictly limited, and the Agency will be glad to advise gratuitously on receipt of particulars to the office, 9, 10, and 11, Poultry, London, E.C. A stamped addressed envelope should be inclosed.

## THE ACETYLENE LIGHT IN OMNIBUSES.

REFERRING to our annotation on this subject in our issue of March 1st, p 608, Mr. Thomas H. Lewis, manager to the "Portable Gaslight, Limited," of 109, Victoria-street, Westminster, states that they have a system at present in use on one of the London Road Car Company's omnibuses in which the acetylene is generated in a carbide of calcium cartridge containing a purifier which entirely absorbs phosphoretted and sulphuretted hydrogen before the gas passes from the purifier. This is exactly what, as we suggested, might be done. Assuming that the purifier does its work properly the acetylene would then be deprived of its poisonous properties.

## TRAVELLING TIME ALLOWANCE FOR LOCUM-TENENTS.

*To the Editors of* THE LANCET.

SIRS,—I would like to suggest through your columns that it would be only fair and reasonable in the case of locum-tenents who frequently have to make such long journeys to and fro a post, occupying either way the greater part of a day, that the length of the engagement should be reckoned from the time of starting to the time of return. The work is so uncertain and the wastage so great, whilst the convenience to established men of being suited to their own time for holiday-making, &c., so useful, that the allowance should not be grudged. I am, Sirs, yours faithfully,

March 12th, 1902. LOCUM.

◆

*A Forty Years' Subscriber.*—There have been a great many references to cremation in THE LANCET during the last 17 or 18 years. Two of these were leading articles—namely, on Feb. 7th, 1885, p. 259, and May 14th, 1893, p. 1338. Among the contributions specially favourable to cremation mention may be made of those which appeared on August 8th, 1891, p. 314; August 15th, 1891, p. 401; and June 17th, 1899, p. 1661. Sir Henry Thompson's book, "Modern Cremation" (Smith, Elder, and Co., fourth edition, 1901, price 2*s.*), should be consulted, and other literature will probably be obtainable from the Cremation Society, 324, Regent-street, London, W.

*Docmed* can obtain all the details concerning the medical curriculum from the Students' Number of THE LANCET, Sept. 7th, 1901. The average student, from start to finish, takes nearly six years in completing his curriculum. We cannot suggest a way in which our correspondent could earn anything during his student days, nor would he find that he had much spare time if he joined a medical school.

*Medico.*—Certainly THE LANCET has never recommended this quack treatment. Our correspondent will observe that no detailed reference is made to our columns. Occasionally we, or more often some of our contributors, may speak well of a drug in connexion with a certain disease. Then a quack will make some sort of concoction of this drug and will claim that his nostrum has our approval.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY** (17th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. ## PUBLIC VACCINATORS AND GUARDIANS OF THE POOR.

IN THE LANCET of March 1st, p. 639, we described the controversy which has been going on between the guardians of the poor for the Holbeach district of Lincolnshire and the public vaccinators for the same district. Certain members of the board were desirous that the present contracts with the public vaccinators should be terminated at the end of 28 days and accordingly a motion to this effect was brought up at the meeting of the guardians held on March 6th. The motion, however, was lost by nine votes to six. In the course of the discussion Mr. Dring made the very true remark that "no professional men work harder than medical men and none are worse paid." The main point at issue which determined the moving of the proposal to terminate the contracts was that many persons preferred being vaccinated at their own homes to calling at the surgery of the public vaccinator, this entailing a higher fee. This is only natural, and it is also only fair that if a public vaccinator has to make a journey to a patient's house he should then be paid at a higher rate than if the patient went to him. Naturally enough the average ratepayer thinks that he may as well get something when he gets the chance out of the rates as he has to pay for such a number of things which are of no use to him personally, although of great use to other persons, such as free libraries, wash houses, and board schools. But it is not fair—and we congratulate the Holbeach Board of Guardians on seeing the point—for ratepayers to make the medical men of the district pay for saving them trouble.

## "AMERICAN SPECIALISTS."

eorge Lillian, Emma Lillian, and Mabel Lillian, their daughter, alling themselves the "Lillian American Herbal Company," were harged at the Ennis Assizes before the Lord Chief Justice of reland with obtaining money by false pretences. The prisoners ere unqualified medical practitioners. The trial commenced on arch 4th and, as reported in the Clare *Saturday Record* of March 8th, t reads like a scene from "Handy Andy." In the end the jury disagreed and the prisoners were put back to take their trial at the next assizes. George Lillian's bail was fixed at the following amounts:—That on or before March 15th he paid £23 to the Crown Solicitor and that he entered into his own recognisances for £50. Emma Lillian and Mabel Lillian were to enter into their own recognisances of £10 to appear. It will be interesting to see the result of the new trial if it ever comes off.

## ADVERTISEMENT.

CORRESPONDENT has drawn our attention to the fact that the illustrated price catalogue issued by Parkes's Drug Stores, Limited, ontains a list entitled "Consultants in London." Of course such ists are quite useless to the public but we do not suppose that the roprietors of Parkes's Drug Stores, Limited, know this. The list onsists of names only and does not pretend to recommend individual actitioners. It cannot be said to advertise anyone though one or o medical men are misdescribed in it.

## WANTED—A HOME.

*To the Editors of* THE LANCET.

SIRS,—I am seeking the publicity of THE LANCET to ascertain if there is any home or institution that would be willing to take charge of a poor creature seriously afflicted with chorea. For 20 years this woman, now 35 years of age, has suffered from this terrible malady, though absolutely helpless she is perfectly sane and conscious of her dreadful position. Her father and mother, aged respectively 74 and 75 years, are past work, one delicate sister lives at home and assists to the best of her ability, another sister, in service, out of her earnings gives what help she is able. The invalid herself is in receipt of a pension from the Royal Hospital for Incurables which is annually augmented by a few kind friends [illegible] that she is in a position to make a small payment if a home can be found for her. Any information or suggestions addressed to the Rev. H. Brass, St. Matthew's Vicarage, Redhill, who has known the family for many years, or to me at aglands, Reigate, would be much appreciated by

Yours truly,

A. D. WELCH.

March 10th, 1902.

## MR. YORKE-DAVIES.

N. E. YORKE-DAVIES, L.R.C.P. Lond., M.R.C.S. Eng., L.S.A., M.D. Dub., is singularly unfortunate. In THE LANCET of Nov. 9th, 01, p. 1313, we called attention to the fact that he had written a long etter in *M.A.P.* of Nov. 2nd lauding his own knowledge and his methods of treatment in cases of obesity. Mr. Yorke-Davies explained that he had written this letter to Mr. T. P. O'Connor as a personal friend and implied that Mr. O'Connor had made a mistake in publishing the letter and we published this explanation in THE LANCET of Nov. 16th, 1901. At the same time we pointed out that the editor of *Modern Society* had apparently also made a mistake and had published another long letter from Mr. Yorke-Davies about Marienbad and what "I have pointed out for many years." Mr. Yorke-Davies did not explain how this letter came to appear, but only remarked that he thought it hard that lay papers should not advertise medical men. Mr. Yorke-Davies has now broken out in a fresh place and in the issue of *Modern Society* of March 8th gives his views upon fat people and the coronation. He is much exercised because each person will be allotted only 16 inches of seat room. He also points out that Professor Schweninger's experience in obesity is entirely borne out by his own. This is curious for in the article in *M.A.P.* to which we have referred above Mr. Yorke-Davies said: "If a person wants to lose weight advise them to go to the expert who can do it without harm. Many patients of Schweninger whose system of reducing weight is the dry one come to me." This looks rather as if Mr. Yorke-Davies's experience differs from that of Professor Schweninger. This point however is of no importance but Mr. Yorke-Davies proceeds in his old unblushing manner to dilate upon obesity and its treatment and to say: "I have pointed this out for years. "I think it will be admitted that I speak with some authority on the matter. I know your paper circulates among those who make a point of enjoying life and they will be apt to think me rather a lugubrious preacher, but life has greater and more lasting pleasures than the pleasures of the table." To this last platitude no one can take exception but Mr. Yorke-Davies must know perfectly well that he owes something to his profession, and it is not fitting that a member of that profession should write to lay papers and practically say "I am the man to go to for the treatment of obesity." The various bodies from whom Mr. Yorke-Davies has obtained his diplomas might, we think, suggest to him to mend his manners. Of course, the last effusion may have been a private letter to the editor of *Modern Society*, in which case we offer Mr. Yorke-Davies our warmest sympathy on being so constantly misunderstood by editors.

## FOUNDLING CHILDREN IN FRANCE.

*To the Editors of* THE LANCET.

SIRS,—I have read with great interest the article by Dr. Charles Goring on "Foundling Children in France," in your issue of Feb. 22nd, p. 541. Are we to understand, however, that *no responsibility* remains with the parents in such cases—that, in fact, the children are simply given up to the care of the State by the parents? Because if so, it seems to me to be merely putting a premium on improvidence and immorality.

I am, Sirs, yours faithfully,

WALTER DUNSTAN, M.R.C.S. Eng.

Liskeard, Feb. 25th, 1902.

## WANTED—A HOME.

*To the Editors of* THE LANCET.

SIRS,—I should be glad to know of a home for an old gentleman, 82 years of age. He is able to get about and to look after himself. His health is fairly good. He suffers from recurrent attacks of stricture, but is able to relieve himself with the catheter. His friends would pay about 5s. weekly. Thanking you in anticipation,

I am, Sirs, yours faithfully,

R. T. W.

The Limes, Hoe-street, Walthamstow, N.E., Feb. 26th, 1902.

## CIGARETTES MADE WITH SPECIALLY PURE PAPER.

IN an assortment of cigarettes sent to us for examination by Messrs. Baron and Co., of 1, Piccadilly, W., a special kind of paper is used as the wrapper which is said to be made from the purest material possible. Our analysis confirms this statement. The paper yields not more than 6 per cent. of ash, consisting chiefly of calcium carbonate, while the weight of each wrapper only just exceeds half a grain. The wrapper labelled "Parasimos" has a design upon it which we find to be in Dutch gold or fine copper leaf. The cigarette marked "King's Guard Argent" contains a very good quality of Dubec tobacco. The lettering on the wrapper is printed in nickel according to our examination. The "Pavilion" straight cut cigarette has no metal lettering upon it at all but chocolate coloured type. Steps are evidently taken to render these cigarettes free from reproach, the tobacco, both the Virginia and Dubec, is of excellent quality and the paper wrapper is pure, of a minimum weight, burning freely and yielding no acrid products of combustion.

## MANUFACTURE OF OZONE.

*To the Editors of* THE LANCET.

SIRS,—I shall be much obliged if any reader of THE LANCET can inform me through your columns where a patient of mine can obtain, on loan or otherwise, local apparatus for the production of ozone. My patient suffers from purulent bronchitis.

I am, Sirs, yours faithfully,

INQUIRER.

March 11th, 1902.

## PHOS-LIGHT.

*To the Editors of* THE LANCET.

SIRS,—Early in the year I had occasion to travel from 4.25 to 5 p.m. with three children aged 12, 7, and a year and 10 months in a "Stamford Hill" omnibus. The baby was tired and fell asleep at once and remained asleep until the end of the journey. The smell from the lamp (Phos-light) was so disgusting that the elder children felt sick and wanted to leave the

# EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

---

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only.* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

# MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1901, which was completed with issue of Dec. 28th, and the Title-page to the Volume, are given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

---

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

---

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

## METEOROLOGICAL READINGS.

**During the week marked copies of the following newspapers have been received:**—*Cornishman, Cornish Telegraph, Torquay Directory [illegible], Devon Journal, Hertfordshire Mercury, Windsor and Eton Express, Portadown News, Sunday Magazine, Kensington News, Daily Telegraph, St. James's Gazette, Revue Américaine de Sciences Médicales, Pharmaceutical Journal, Manchester Guardian, Dublin Evening Telegraph, Southampton Echo, Bedford Advertiser, Coventry Herald, Belfast News, [illegible] Daily Mail, Municipal [illegible], Allgemeine Medicinische Central Zeitung, Il Policlinico, [illegible] Courier, Aberdeen Free Press, [illegible] Weekly [illegible], de San Paulo, [illegible], Bristol Mercury, Liverpool Daily Post, La Caducée, Hong Kong Weekly Press, Herts Advertiser, Times of India, Reading Mercury, Mining Journal, Local Government Chronicle, &c.*

eight divisions is considered by Mayr to be a genus and each of the sub-divisions a species—that is to say, a distinct disease and not a mere variety. This is clearly shown by the sub-divisions of Genus V.—viz., small-pox, measles, and scarlet fever—which are obviously distinct diseases. I may at once draw attention to the remarkable fact that he includes pulmonary phthisis among fevers as the only species of Genus VIII., entitled "Febris lenta, hectica." He does not, however, tell us whether he considers phthisis a *contagious* fever or not, but he probably did, as throughout the southern parts of Europe it has always been considered a contagious disease. His first genus is continued fever, of which he considers that there are two species. His second is typhus, of which he describes five species, which he styles "diversae species," as follows:—

"Primo. *Typhus verus pestilens contagiosus seu Pestis orientalis.*" By this he no doubt meant true contagious typhus fever, with which the oriental plague was associated and confused up to that time and later still, for he says further on in his treatise that to the genus called typhus belong "the fever of hospitals, prisons, camps, ships, and many others, as also especially the true Pestis orientalis." He therefore recognised that his first species of typhus was the fever of prisons and other crowded places.

"Secundo. *Typhus verus gangraenosus, contagiosus, icterodes, pestilens*, vocatur etiam *Pestis occidentalis*, seu *Febris pestilens, contagiosa, epidemica flava americana.*" Or true contagious yellow fever

"Tertio. *Typhus verus non-contagiosus putrido-biliosus* seu *bilioso-putridus*, seu *Febris putrida sanguinea* STOLLII, seu *putrida saburralis* STOLLII qualem sordes putridae e systemate gastrico in sanguinem attractae generare solent. In *putrida sanguinea* vero vitium in systemate sanguineo primario natum; a colluvie bilis putridae in sanguine seu secundis viis abundantis nata, vel ex primis viis in secundas delata; vocatur quoque *Typhus mitior*, lentius decurrens, non contagiosus, vel *Febris putrida non contagiosa*" A perfectly clear and unmistakeable definition of one of the varieties of typhoid fever, of which he further says, so that there cannot be the slightest doubt about the matter: "Haec Species *Typhi* potissimum cum inflammatoria febre aut topicis affectionibus complicata esse solet, cum aut sine exanthematibus; inde Peripneumoniae malignae, Hepatitides, Dysenteriae et Mesenteritides gravissimae etc. observantur."

"Quarto. *Typhus verus nervosus seu pituitosus non contagiosus*, seu febris nervosa, seu febris lenta nervosa anglorum, vel febris putrida pituitosa Stollii, a pituita acri et putrescente ortus, tarde decurrens." Another well-known variety of typhoid fever of which he remarks: "Haec Species *Typhi* cum inflammatoria et biliosa febre ac topicis affectionibus, cum aut sine exanthematibus permixta et complicata esse solet." And further adds the following shrewd observation which anyone who has had anything to do with the treating of cases of typhoid fever will agree with: "In nullo morborum genere tanta opus est patientia, exspectatione cunctationeque ad bene et feliciter medendum: est enim difficilis hujus morbi Diagnosis et Therapia." Typhoid fever is described as "nervous fever" by Gilchrist, Huxon, and Manningham; as "nerven fieber" by German writers; "fièvre nerveuse" by the French; and "low fever" or "brain fever" by many English writers.

"Quinto. *Typhus spurius seu fictitius.*" Apparently equivalent to the *embarras gastrique* of French authors. He says that it is often confused, as might be expected, with the *typhus verus* of the third or fourth species—i.e., with typhoid fever.

These five species of "typhus" Mayr considered to be distinct diseases, but his third, fourth, and probably fifth, were evidently our typhoid fever, in which he thus recognised either two or three diseases; and who shall say even now that he was wrong? It would not be in the least degree surprising if it were definitely proved that under the term "typhoid fever" we now include at any rate two quite distinct diseases. Mayr, therefore, clearly distinguished between typhus and typhoid fevers. He put them down as separate diseases belonging to the same genus, typhus being a contagious fever and typhoid, including the third, fourth, and fifth species of the genus, being non-contagious. It becomes now exceedingly interesting to ascertain what further differences he points out between the two diseases. He says under the heading, "*Diagnosis Primae et tertiae Speciei Typhi*": "The symptoms of the first and third species of (that is to say, of typhus fever and typhoid fever) are in common and very similar except that in the first species of typhus more bad symptoms appear in the sick than in the third species of typhus, and that in the first species of typhus bubones, anthraces, vibices, are more often observed than in the third species of typhus, and that the first and second species of typhus (i.e., typhus and yellow fever) often prostrate even the most healthy men by contagion contracted, which does not happen in the third non-contagious species, but (in which) the prodromata precede a long time before the disease breaks out; and that in the first and second species of typhus on account of their contagious nature the mortality is far greater than in the third and fourth non-contagious species of typhus." Under the heading, "*Causæ harum febrium*," Mayr says: "Besides contagion, which affects different people in various ways, there is also a pestilential contagious *poison* which is transferred and communicated to others in the *first species of typhus* from the infection of one suffering in a similar way; as in the typhus of the first species, so also in the *non-contagious typhus* of the third species it supplies the cause, it deprives of all the force of life, it depraves the humours, it relaxes the system." He then gives a number of predisposing causes, among which are warm and moist air, the close atmosphere of ships, hospitals, vaults, camps, crowded cities, &c. Air contaminated with the effluvia of pools, of animals, and vegetables, especially of putrid things, &c. It will be noticed that he mentions overcrowding first and that he no doubt refers to as the cause of true typhus fever. He then goes on to putrid substances, but it is too much to conclude from this that he therefore understood that these were the causes of the third, fourth, and fifth species of his genus of typhus—that is to say, of typhoid fever. Further on in his book he refers again to contagion at some length in a chapter entitled *De Contagiis*, towards the end of which chapter he says: "It is, moreover, to be noted that certainly not all the typhode contagions are of so volatile a nature that they are always and absolutely spread abroad and volatilised in the atmosphere, and therefore (other things being equal) can act only in true epidemic fashion, but that many of them, and some of the most virulent and malignant, as long at least as a strong degree of heat does not act upon them, show a sufficiently fixed character and remain fixed for a longer or shorter time upon various other bodies which catch them—viz., upon different goods, especially those of wool and cotton, of silk, of leather, feathers, flax, or the hairy skins of animals, clothing, paper, wood, beds, walls, and buildings, and often after many months they break out from these hiding-places still in full force, they infect the atmosphere, and propagate disease and death far and wide."

I must now direct your attention to another remarkable treatise, the work of J. Val de Hildenbrand, Professor of Practical Medicine at the University of Vienna, which was published there in 1810, and a translation of which was published in Paris in 1811. In this treatise the author maintains that the word "typhus" has been improperly employed to designate a *genus* of disease, and that it ought to be used as the name of a particular *species*. He says that the true typhus has often been mistaken for another fever, just as certain other fevers have been mistaken for typhus. "But," he says, "in order to avoid all further dispute about the name of a disease of which the primitive meaning has been lost by an abuse of language, I declare that I treat in this work of the true *contagious typhus* alone, which develops in the human body its special poison by means of which it afterwards spreads, which is everywhere and always perfectly like itself, and of the same essential nature, because it proceeds from a poison *sui generis* and always the same, which disease in fine ought alone to bear the name of typhus because it possesses the special characters expressed by that word. Contagious typhus is an essential fever the course of which displays a constant uniformity. It is a fever of a *special species*—as small-pox, for example. It is contagious because by means of a special substance which develops during the disease it is transmitted and communicated to those who are predisposed to it. By reason of an eruption which is peculiar to it it belongs to the family of the exanthematic fevers, among which the contagious fevers ordinarily find their place. It has a course determined in measured periods and also different characters in its different periods, but with a constant symptom throughout the whole course of the disease, which is stupor with delirium or 'typhomania.'" And he goes on to distinguish it from the fevers known by the names of malignant, nervous, asthenic, putrid, and bilious—in fact,

# The Milroy Lectures

ON

# THE ETIOLOGY OF TYPHOID FEVER AND ITS PREVENTION.

*Delivered at the Royal College of Physicians of London on Feb 20th, 25th, and 27th, 1902,*

BY W. H. CORFIELD, M A, M D. OXON., F.R C P. LOND,
PROFESSOR OF HYGIENE AND PUBLIC HEALTH AT UNIVERSITY COLLEGE, LONDON, CONSULTING SANITARY ADVISER TO HIS MAJESTY'S OFFICE OF WORKS

## LECTURE I

*Delivered on Feb 20th, 1902*

MR PRESIDENT AND GENTLEMEN,—When the Council of the College paid me the unusual compliment of requesting me to deliver the Milroy Lectures this year I felt that although my time was more than fully occupied I could not refuse the honour so graciously offered me and I therefore accepted the duty without hesitation Had I, however, known that I should have to go through a serious illness towards the end of last year—an illness from which I have not yet fully recovered—I should certainly have shrunk from the ordeal I have chosen the subject of typhoid fever partly because it has not been treated before in these lectures (although Dr P Horton Smith delivered his Goulstonian Lectures on the Typhoid Bacillus in 1890), and partly because I have had an unusual experience of that disease from many points of view I studied it under William Jenner—of whose part in elucidating it I shall have something to say further on—35 years ago Soon after that I went through a severe outbreak of it while prosecuting my post-graduate studies as Radcliffe Travelling Fellow of the University of Oxford at Lyons—an epidemic which filled all the medical wards and half-filled all the surgical wards in the hospitals of that city with cases of typhoid fever of every variety Since then much of my time has been occupied in investigating both large and small outbreaks of the disease, in studying the conditions under which it spreads and the means of preventing it, whether in the form of widespread outbreaks or of cases in households During these investigations I have, of course, been exposed to the infection of the disease on very numerous occasions, of which I may especially allude to one where I traced a severe outbreak in a small country town to the contaminated water of the well at the hotel in which I was staying I attribute my immunity during all these numerous exposures to the fact that I well remember suffering when a boy from what was called "brain fever" The first medical paper I wrote was entitled "On the Alleged Spontaneous Origin of the Poison of Enteric Fever" It was read before the Epidemiological Society of London in March, 1874, and will be alluded to at length further on

I have used the name "typhoid" in the title of these lectures in preference to "enteric" fever, as it is the oldest name now in use—the name which Jenner used and of which Louis says, "it is almost free from objection," and also a better name than "enteric," as it expresses the fact that it is a disease which resembles typhus fever—a fact which cannot be gainsaid, as it was confused with it by all the astutest physicians up to near the middle of the last century "Typhoid" is also a better name than "enteric" for a general disease, for we do not call other fevers by names merely denoting the organs in which their most specific lesions occur. As Dr Charles Murchison says "It would not be desirable to have any name derived from the abdominal lesion, tending, as this would do to revive in the minds of many the exploded doctrines of Broussais"—viz, that the fever was caused by the intestinal inflammation I may also add that the name of the organism now identified with the disease is "bacillus typhosus" and not bacillus entericus or enteritidis

The historical part of the subject has been so fully treated by Dr Murchison, who has given us a summary of the history of typhoid fever from the time of Hippocrates onwards, that it is quite unnecessary for me to go into the early part of it in any detail I think it desirable, however, that I should go at some length into the question of the knowledge of this disease at the beginning of the last century and of the development of such knowledge since, by giving an account in some detail, and as far as possible in the words of the authors themselves, of the most important works on the subject since the early part of the last century—works which have really advanced our knowledge, written by great masters, the medical giants of their day.

In the first place I wish to introduce to your notice a hitherto unknown author, a copy of whose work I have found in the library of the Royal Medical and Chirurgical Society I refer to him as an unknown author because his work is not referred to by Dr Murchison, although he cites a great number of authors both on typhus and typhoid fever, nor, so far as I can find, is it referred to by any other writer. There is no copy of this work in the library of our College or in that of the Medical Society of London, or even in that of the British Museum The copy that I found in the library of the Royal Medical and Chirurgical Society has been there for many years, but has been read by no one, as its leaves had not been separated when I found it. It is written in Latin and is entitled, "Specimen Practicum de Remediis Efficacissimis in Morbis Contagiosis ac Pestilentialibus adnexa Commentatione de Contagiis et Febribus Typhodeis" It was written by Christopher Mayr, Doctor of Medicine, "olim Variorum Nosocomiorum Medico Secundario, ac Quondam S S Caes Reg Apost Maj Status Militaris Medico Supremo, et Magni Nosocomii Militaris Vindobonensis Medico Primario Collegii Medici Vindobonensis Sodali and was published in Vienna in the year 1806 In this treatise fevers are divided into eight classes or genera (see Table I)

TABLE I

*Conspectus Febrium —Febres Principes Elementares seu Cardinales*

I
Synochus imputris seu Febris Continua non putris
1 Febris Inflammatoria
2. Febris biliosa
3 Febris pituitosa

II
Synochus putris utplurimum Malignus, seu Febris continua putrida utplurimum maligna
Typhus Quinque species Typhorum

III
Febris intermittens

IV
Febres continuæ remittentes seu composita
et
Febris ardens seu καυσος

V
Febres epidemicæ intercurrentes
Variolæ
Morbilli
Scarlatina

VI
Febris indeterminata, nova, incognita

VII
Febres Sporadicæ et Singulares
Febris lactea
Febris puerperalis

VIII
Febris lenta, hectica
Phthysis pulmonalis

The five species of typhus under Genus II are shown in Table II, as follows —

TABLE II.

*Quinque Species Typhorum*

Primo *Typhus verus pestilens contagiosus seu Pestis orientalis*
Secundo *Typhus verus gangraenosus, contagiosus, Icterodes, pestilens vocatur etiam Pestis occidentalis, seu Febris pestilens contagiosa epidemica flava americana*
Tertio *Typhus verus non contagiosus putridus biliosus seu bilioso-putridus seu Febris putrida sanguinea seu putrida saburralis*
Quarto *Typhus verus nervosus seu pituitosus non contagiosus, seu febris nervosa seu febris lenta nervosa anglorum vel febris putrida pituitosa a pituita acri et putrescente ortus, tarde decurrens*
Quinto *Typhus Spurius seu fictitius*

By this most interesting classification of fevers we are able to understand exactly the view taken of them at the beginning of the last century, and from the accurate descriptions given of some of them in Mayr's book we are able also to understand how much was known about them and how far they were distinguished one from another Each of these has not fixed the attention of those who have described epidemics of typhus." And only three pages further on he says: "From the present time it must be acknowledged that every acute affection which is not accompanied in its course with the special alteration of Peyer's patches is not a typhoid affection, although one does not find in the autopsy the signs of any other affection, and thus the typhus fever of the English is necessarily a very different disease from that with which we are engaged." And then speaking of the observations of Dr. Shattuck of Boston he adds: "That which reasoning forces us to admit direct observation has proved, and we must recognise henceforth that there exist in England, and in London in particular, two febrile affections hitherto confounded together, but really very distinct, which only resemble one another in a general manner, of which one only attacks young persons, is accompanied ordinarily from the outset with local symptoms in the abdomen, afterwards with an eruption of *taches roses lenticulaires;* whilst the local symptoms, the diarrhœa, the meteorism, are more or less completely absent in the other which is accompanied by an eruption very different from the first and also much more abundant, and attacks person of every age." He adds much to his chapter of causes and points out that in typhoid fever "passing the night in places situated low down and inhabited by too many persons cannot be one of the causes, as only the eighteenth part of the cases fulfil this condition." He actually gives one case, "Observation 54 bis," where the use of a putrid water in which a certain amount of chopped-up hay had been mixed was followed by a well-developed and fatal case of typhoid fever in which the ulcerations of the Peyer's patches were found after death. With regard to the question of contagion, which he did not touch in the first edition of his work, he comes positively to the conclusion that it is a contagious disease, and that the Paris physicians had denied this because in a great city it is difficult to trace the course of contagion. He quotes largely from the work of M. Gendron of Château-du-Loir on epidemics of small places to prove that the disease is transmitted directly and indirectly from person to person. He also quotes from the same author some remarkable instances proving the immunity conferred by an attack of the disease, and at the same time proving its contagious character. These are so interesting that I think them worth quoting, as follows:—

1. Three journalists contracted the disease at a certain house, two communicated it to their families, the third did not do so, he was looked after by his wife who had had the disease several years before.

2 A domestic servant of Contereau transmitted typhoid fever to his sister, the niece of his master and mistress, and these visited her without danger. They had had the typhoid affection four years before.

3 At Petit-Gênes a young man infected all who looked after him except his father and mother; these had both previously had dothinenterie; the husband 20 years and the wife two years before the epidemic which this very son started.

4. In 1829 the same disease was imported into a fresh family at Petit-Gênes and did not go beyond it, in spite of the visits of the inhabitants of the hamlet, which had already been once attacked.

5 At eight years apart two epidemics attacked Coemont and the second spared all those whom the first had not spared.

He concludes, then, first that the disease observed in these country places by MM. Bretonneau, Leuret, and Gendron whether in the sporadic or epidemic state was unquestionably typhoid fever, because the characteristic anatomical lesion was commonly found among those who died from it and "it must be recognised therefore that the typhoid affection is contagious, at any rate in the departments." But he adds that others have since made similar observations in Paris. Thus, M. Putegnat "has reported that after a visit made to a person who returned from a village where typhoid fever prevailed a woman was attacked by this disease and a few days afterwards her husband and their six children were also attacked. A single person escaped—she was 82 years of age. M. Putegnat also reports other similar facts which leave no doubt as to the contagious character of the disease." And he finally concludes: "It seems to me henceforth impossible, after all that goes before, to deny the contagious character of the typhoid affection, even in Paris."

I will next draw your attention to the work of Professor A E Chomel entitled "Leçons de Clinique Médicale (Tome I., Fièvre Typhoide)," published in 1834, but delivered before then. Dr. Chomel considered typhoid fever a separate and distinct disease from typhus fever and gave it the name of typhoid fever. In his introductory remarks he says that the fevers described by different authors, including himself, "under the name of grave continued fevers, under whatever form they show themselves, whether inflammatory, bilious, mucous, adynamic, ataxic, nervous, are only varietie of one of the same affection which has received differen names (entero-mesenteric fever of MM. Petit and Serre intestinal exanthema of M. Audral, *dothinentérie* c *dothinentérite* of M. Bretonneau, *iléo-diclidite* of M. Bally follicular enteritis of many pathologists). We shall prefe ably call it by the name of *typhoid fever* or *disease*, becaus of the analogy which it offers in its symptoms with th typhus of camps." He goes on to add that the variou fevers mentioned above have common characters whic forbid them being considered as separate diseases "*an are especially bound together by a series of anatomica lesions which one does not meet with in any othe disease.* The typhoid affection will therefore occupy i nosology a position of great importance because it almos takes the place by itself of a whole class of diseases." H then describes most minutely the symptoms and course o the disease, describing, among other things, the specia eruption in the following words: "One sees appear ordinaril from the seventh to the ninth day that altogether peculia eruption which is special to typhoid fever and consists i small *taches rosées*, disappearing by pressure, of from half line to two lines in diameter, round in shape, withou elevation or scarcely elevated above the skin, scattered ove the abdomen, sometimes over the chest, more rarely over th thighs, the arms, and the forearms." Further on he point out that "the *taches rosées lenticulaires* are easily distinguished from the petechiæ and from the bites of fleas, because in these latter there is extravasation of blood at the surface of the dermis, and that their colour, instead o lessening under the influence of pressure, becomes more pronounced by the discolouration of the skin which surround them. In the typhoid spots, on the contrary, the rednes disappears altogether, as in erysipelas, where there i evidently congestion, and where, when the pressure ceases, one sees the redness reappear immediately." Further on, again, he points out that in a certain number of cases there is intestinal hæmorrhage and sometimes perforation, of which he says: "Perforation of the intestinal walls is the most grave of the accidents which can happen in the course of the typhoid affection, for it almost inevitably results in the death of the patient." He mentions that M. Louis reported that he had observed intestinal perforation eight times in 55 persons who had died from typhoid fever, a proportion of one in seven. In discussing the lesions produced during the course of the disease he says: "The anatomical lesions which constantly or almost constantly accompany the typhoid affection are situated in the follicles of the intestines and the mesenteric glands. These are the only lesions which one meets with in almost every case." He includes in the follicles of the intestines the isolated ones (Brunner's glands) and the agglomerated ones (Peyer's patches) and further on he describes minutely the ulceration of the follicles. Like all the other authors of the time he finds that "the causes of typhoid fever are involved in the greatest obscurity." With regard to the question of contagion he points out that "there is a great difference of opinion among medical men—the majority in France deny every kind of contagion in this disease. A few, however—perhaps 1 per cent.—think that typhoid fever ought to be classed among the contagious diseases." He then states the arguments of the non-contagionists, which he says were generally received and admitted without opposition until the time when M. Bretonneau in 1829 adopted the opposite opinion. He points out that the first reason why contagion has been denied to this malady "is that of all the persons who can surround a patient attacked with typhoid fever there are few who are susceptible of contracting the disease. One understands in effect that the father, the mother, the doctor, the nurses, many of the sick in hospitals, are immune to the contagion either because most of them have already passed the age at which the typhoid disease is most commonly developed, or because they have already been attacked by it, or, lastly, because they are among the number of those who are immune by constitution Another reason is that in hospitals on account of the good ventilation such diseases even as small-pox are not readily transmitted from one patient to another." He also points out that the negative proofs on which the anti-contagionists rely are entirely from observations made in Paris. "But it is not in cities as large as Paris that one can study contagious diseases from the point of view of their transmissibility, because of the difficulty, or even of the impossibility, in most of the cases to trace there the course of the contagion. ...... It i from the fever which we now know under the denomination of typhoid. He then describes the varieties of contagious typhus under the names of pestilential or oriental typhus (the plague), perhaps also occidental typhus (the yellow fever of America) and ordinary typhus Of the latter he says that it is peculiar to Europe and we must include under it, *but only as so many varieties*, the typhus of hospitals and lazarettes, of prisons, of camps, of vessels, and of besieged cities, showing clearly that by it, he means what we understand as typhus fever and that he was quite aware of the circumstances under which it flourishes In Section VI of this work he discusses the causes and modes of development of the disease He says that it is always produced by contagion and that one attack of it almost always destroys for a certain time, but rarely for the whole of life, the susceptibility to the disease He says that the contagion is spread by means of clothes, woollen stuffs, furs, linen, dirty bedclothes, and even by beds of straw or of hay on which typhus patients have lain He disputes the view that the air of marshes has anything to do with the disease, pointing out that it produces fevers of the intermittent type For him overcrowding is the cause of typhus fever, although he gives all credit to previous observers in the following sentence "Army doctors by exact researches have been the first to show us under what circumstances and how the air can become the cause of typhus, R Minderer, D Monro J Pringle, and others have specially pointed out the dangers which air produces when it is overcharged with human exhalations *There is in truth the source of the contagious matter and of the contagion of typhus* It is equally recognised and too much confirmed by terrible examples that the exhalations of healthy men crowded and pressed together in too small a space have also the most harmful influence upon health In prisons, houses of correction small rooms of vessels, and in all the establishments where many men otherwise healthy live together in too great a number the air offers the same danger' He also insists that the disease may be avoided by preventing overcrowding "As the atmosphere of hospitals, or of any other establishment deteriorated and overcharged with exhalations, especially with exhalations of sick persons is the only originating cause of typhus and as the best method for preserving against this terrible disease consists solely in diverting these causes and in insuring a pure and respirable air, every authority, as soon as it is convinced of the importance and utility of this object, should take care to have recourse to measures which are the most salutary and the most suitable to attain this end Such is certainly the duty of Governments they watch over the sick with so much solicitude, they go to so much expense for food medicines, and commodities of all kinds, and why should they neglect to pay attention to that which is the most necessary to the sick, to the purity of the air as the indispensable element of life and of which the bad qualities are so often dangerous?" The next sentences are so remarkable and so much in advance of the time that I am sure I shall be pardoned for quoting them also "What is there beneficial to suffering humanity when in a hospital and in a military lazarette a considerable number of sick persons are found crowded together and infected one after the other by the foul air? Would it not be more suitable to place these sick persons in barns or in attics in the open air than to crowd them in rooms? One would avoid in that way many dangers and misfortunes One is even sometimes prodigal in providing warmth for sick persons. Why should one not be so in ensuring pure and sufficient air? Air is more useful than warmth Want of warmth can sometimes be replaced by diet or medicines, want of air can never be replaced either by the best diet or by the most expensive remedies Civil and military authorities ought never to lose sight of this important truth It is the duty of all those who are called upon to work for the good of humanity to have their minds imbued with this idea in order to attain the desired object.' It is thus quite evident that this author in the early years of the nineteenth century had a perfectly clear idea of what typhus fever was, of its causes, and of the way to prevent it He says in the most positive manner that it is a distinct disease from the other continued fevers which we now know as varieties of typhoid

The most important early work on typhoid fever, however, is that of M. Louis the first edition of which appeared in 1829 under the title of "Researches on the Diseases known under the Names of Gastro-enteritis Putrid, Adynamic, Ataxic, or Typhoid Fever," &c It was dedicated to M Chomel, Professor of Clinical Medicine at the Paris School In this first edition M Louis describes, with the hand of a master, typhoid fever in the minutest manner He maintains that the ulceration of the Peyer's patches is its characteristic lesion and he says "*Except the alteration of the elliptic patches* all the lesions of the mucous membrane of the smaller intestine observed in cases of the typhoid affection existed in persons who had succumbed to very different acute diseases' And again "The elliptic patches of the small intestine having only shown alterations in the subjects dying from the disease which is the principal object of these researches this alteration having been constant, ordinarily very severe, always developed according to the same law whether death has arrived after eight days of the disease or after a much more considerable length of time, and in some cases, so to speak, the only lesion, it must not only be considered as special to typhoid affections, but as forming their anatomical character just as tubercles form that of phthisis whatever has been the cause which has excited their development' He also even in this first edition, describes the "*taches roses lenticulaires*" (N B —He calls them thus by other writers they are generally known as "*taches rosées*"), their distribution and successive crops With regard to the causes he says "While the causes of enteritis are often evident those of the typhoid affection are unknown And again "The most profound obscurity then reigns over the causes of the affection we are considering" The second edition of the work was published in 1841 and was also dedicated to M Chomel[1] In the preface to this edition he refers to the confusion which previously existed as to the continued fevers and says triumphantly "Now that the confusion has ceased it is recognised that the fevers of Pinel, apart from the plague only form one and the same disease of which the anatomical character consists not in an inflammation of the stomach and intestine but in a profound and special lesion of the elliptic patches of the small intestine. Those who up to this time had defended with the greatest energy the doctrine of the fevers have abandoned their point of view and have recognised as M Chomel has done, the exactitude of the facts which I have observed and that of the conclusions which I have deduced from them[2] This change of opinion has taken place not only in France but everywhere where observant medical men have followed the movements of science, and among foreigners the American medical men have been the first to recognise the correctness of my researches" He then quotes a number of American medical men "who, having studied for the most part the typhoid affection at Paris have afterwards many times observed it in their own country with the symptoms and anatomical characters which I have described In this second edition the chief additions that he makes are as follows In the first edition he had stated that the "*taches roses*" were found in other diseases In this one he says "Since the publication of this work I have in vain searched for the spots in question on a number of patients attacked with other acute affections than typhoid fever and I presume that being less familiarised with the typhoid spots 10 years ago than I am now I must have confused small papules with the eruption in question, which explains the apparent contradiction which I have just pointed out This is the confession of a great and truthful observer Further on he complains that "the state of the viscera of individuals who have perished from the different epidemics of typhus has often been neglected, and in this case the most certain and easy means of assuring oneself of the identity or difference between typhus and the typhoid affection escapes us He then quotes M Gaultier de Claubry and authors of other writings and says that "after a fashion these descriptions, although assuredly very incomplete seem nevertheless to show, as far as they go, that the comparative study of the symptoms indicates the identity of typhus and the typhoid affection' It will be noticed how very guarded this sentence is but M Louis was not content with that very guarded statement for he goes on instantly to make the following astute remark:—"One cannot be too much astonished however in admitting this identity that a formidable accident, the perforation of the small intestine it best, for they suggest that "the pyrexia, called in France 'typhoid fever,' *may be* nothing else than a gastro-intestinal inflammation," and M. Bouillaud defines it as follows: "Typhoid fever, or adynamic fever, or entero-mesenteric fever, or dothinentérite, or iléo-diclidite, &c., consists in the inflammation of the small intestine and its follicles plus a *typhoid element*, the nature of which is not agreed on." On the other hand, during the discussion M. Rochoux says positively, "Typhus and typhoid fever are two essentially distinct diseases, as M. Petit has proved, and as I have stated in a treatise myself."

---

[1] In this edition the title was somewhat altered (the name typhoid fever being given a prominent position before the other names of the disease).

[2] In a footnote he here acknowledges the recognition given him by Professor Bright in his treatise on Follicular Enteritis which had just been published

At about the same time that Dr. Lombard of Geneva was making his observations which led him to the conclusion that there were "two distinct and separate fevers in Great Britain, one of them identical with contagious typhus, the other a sporadic disease identical with the typhoid fever or *dothienenteritis* of the French, Gerhard and Pennock of Philadelphia were arriving at the same conclusion from observations of an epidemic of typhus which prevailed in that city in the spring and summer of 1836. Both had previously studied the enteric fever in Paris and were familiar with it in their own country. They at once recognised the difference of the new disease, and after a time they were never deceived in their diagnosis." Their observations were published by Gerhard in February and August, 1837. Gerhard maintained that the typhus of Philadelphia was identical with British typhus, and with the gaol, camp, ship, petechial, or spotted fever, and that it was eminently contagious, while, on the other hand, typhoid fever was rarely communicated. He showed that the lesions of Peyer's patches and of the mesenteric glands, invariably present in the latter, were never found in the former, and remarked that English observers erred in regarding the intestinal disease as a mere complication of typhus. He insisted on the marked difference between the petechial eruption of typhus and the rose-coloured spots of typhoid fever, and he showed that a peculiar train of symptoms very different from those of typhus was associated with the intestinal affection, and that the distinctive characters of the two diseases were such as in practice could not allow them to be confounded. To Gerhard and Pennock certainly belongs the credit of first clearly establishing the most important points of distinction between the two diseases. M. Valleix of Paris, in a review published in January and February, 1839, thus alluded to Gerhard's observations: "M. Gerhard établit d'abord un fait bien important, c'est qu'il peut exister, et qu'il existe en effet, concurremment dans le même pays, deux maladies, qu'on peut parfaitement diagnostiquer, et dans lesquelles on peut prédire pendant la vie du malade, les lésions qui seront trouvées après la mort; ce sont la fièvre typhoïde et le typhus proprement dit."

After this several authorities, especially Dr. Staboroh, Dr. Shuttuck of Boston, M. Valleix, and M. Rochoux, published memoirs pointing out the differences between the two fevers. Of the last mentioned Dr. Murchison says: "He insisted that nothing could be more unlike than the eruptions of the two fevers and that while typhus was highly contagious and generally believed to result from overcrowding the contagious character of dothienenteritis was doubtful and it was independent of overcrowding" (Rochoux, 1840).

On Feb. 6th, 1840, Dr. H. G. Barlow read a very important paper on "The Distinction between Typhus Fever and Dothienentérie" before the Parisian Medical Society, an abstract of which will be found in THE LANCET of Feb. 29th of that year. He insisted that these two fevers were not only different in their lesions but also that "the *fièvre typhoïde* of France is an endemic disease; it is endemic in those localities, as in Paris, where it principally prevails and where the influence of contagion is extremely doubtful and is by many positively denied. The typhus fever of Great Britain and Ireland on the contrary is a highly contagious disease." Further on he says: "I would suggest that two diseases so different in their modes of origin, however nearly in the course of their symptoms they may come to resemble each other cannot be essentially identical. Dothienentérie chiefly attacks those who have only been a short time resident in Paris or in a large city; typhus fever observes no such distinction of persons; the former rarely occurs above the age of 40 years or below that of 10, the latter on the contrary very frequently does. Dothienentérie is at its maximum in autumn and at its minimum in winter. ...... In typhus no such connexion is observed to exist and that disease is often at its greatest height in winter when the former is comparatively rare." He also points out that in typhoid fever "diarrhœa is one of the earliest and most constant symptoms. It usually sets in at the beginning of the disease and continues to its close. It does not appear to be essential, as three fatal cases are mentioned by M. Louis in which it did not occur, neither is there any obvious relation between its amount and the degree of organic lesion which exists, yet its occurrence is almost invariable. In typhus an opposite state prevails and diarrhœa is comparatively rare." After mentioning other differences he describes the eruptions of the two diseases with the greatest minuteness and accuracy. "At about the eighth or ninth day the typhoid eruption, consisting of lenticular rose-coloured spots, *taches rosées*, appears on the abdomen, back, and chest; it is not an abundant eruption and not always present. The spots are about a line in diameter, regular in form, slightly elevated, and disappear on pressure, but return again. They come out in succession, four days being the average duration of each." After describing the sudamina he adds, "Petechiæ have been chiefly noticed in particular epidemics. They vary in diameter from one to several lines and neither project nor disappear on pressure. Vibices occasionally occur." On the other hand, "in the typhus fever of Great Britain and Ireland the eruption is chiefly petechial, often mixed with vibices, appears earlier, on the fourth or fifth day, sometimes before, and is commonly profuse, the amount of eruption bearing a certain ratio to the intensity and duration of the disease. The duration of dothienentérie may be stated on an average of from 20 to 30 days. ...... The average duration of typhus in 43 fatal cases mentioned by Dr. Reid was 12½ days ...... so that typhus appears to run its course much more rapidly than dothienentérie." He sums up the differences between the two fevers as follows: "A difference in the manner of origin, a difference in the seasons of occurrence, and a difference in the modes of attack; a difference in the series of symptoms, a difference in the external appearance, and a difference in the duration of the diseases; a difference in the ages at which they occur, a difference in the sexes in which they principally prevail, and a difference in the mortality which they respectively occasion. While the great and crowning difference of all is the existence of a particular anatomical lesion in one, and the absence of any obvious anatomical lesion in the other. Surely two diseases which differ in all these particulars cannot be identical." No wonder that Dr. Murchison says: "This paper has received less attention from subsequent writers than it deserves." I will go farther than that and will say that although previous writers had foreshadowed the differences between the two diseases, and although some of those writers whom I have mentioned had gone so far as to declare that the two diseases were different from one another, Dr. Barlow was the first man to give a detailed and complete account of the differences between the two diseases and to establish once and for ever that they are entirely distinct from one another. The only important fact in connexion with the two diseases that he does not point out is the difference in their *causes*.

In the same year—viz., on April 16th and 23rd, 1840—Dr. A. P. Stewart read a paper, also before the Parisian Medical Society, entitled, "Some Considerations on the Nature and Pathology of Typhus and Typhoid Fever applied to the Solution of the Question of Identity or Non-identity of the Two Diseases." This paper is an admirable summary of the state of knowledge on the subject at the time and contains an excellent description of the two diseases and their differences. He alludes to the cause of typhoid fever, of which he says: "With regard to the producing cause of typhoid fever all is vague and uncertain, ...... but what chiefly concerns us to know is whether the conditions we have seen to be so powerful in the production of typhus are the same, or anything like the same, in regard to typhoid fever. Exactly on this point Louis remarks: 'No more can the dwelling in places, low and inhabited during night by too great a number of individuals, figure among the causes in question, one-eighteenth only of the patients being in that condition,' and he concludes from a comparison of all the assigned causes with the facts ascertained by himself in these remarkable words: 'The deepest darkness, then, prevails regarding the causes of the affection under consideration.' Chomel likewise uses the same words in beginning his third article: 'The causes of typhoid fever are wrapped in the greatest obscurity.'" As to Dr. Stewart himself he merely says without hazarding any decided conclusion on a not, therefore, by negative proofs collected in a city like Paris that one can support an opinion unfavourable to contagion." Typhoid fever, according to him, only affects the same person once. "This circumstance is an important fact, for there are only a few diseases which attack but once the same person, and among these diseases there is not one which is not obviously contagious; typhoid fever would then be the only exception to this law if it were not contagious like the other diseases with which it shares this important character. Lastly, another point which is in favour of contagion is the analogy which exists between the typhoid affection and the typhus of camps, of which no one disputes the contagious character" He then discusses the resemblances and differences between these two diseases and formulates his conclusions as follows: "1. The opinion adopted by most French medical men that the typhoid affection is not contagious cannot be admitted as demonstrated. 2. If this disease is contagious it is only so to a feeble degree and with the concurrence of circumstances as yet ill-defined. 3. If further observations show in typhus fever anatomical lesions resembling those which one meets with in the typhoid disease the identity of the two affections would be placed beyond doubt and the question of contagion would be solved." Thus, after his minute and accurate account of typhoid fever and his evident conviction that it is a separate disease, he is obliged from his ignorance of typhus to suggest that it may be possible that after all they may be the same disease.

I am relieved from the necessity of describing the works of various other authors before 1835, as in that year two most important memoirs were awarded prizes by the Royal cademy of Medicine of Paris and were published in the Memoirs of that academy. These memoirs were answers to the question, "faire connaitre les analogies et les différences qui existent entre le typhus et la fièvre typhoide dans l'état actuel de la science." The first was by M. Gaultier de Claubry. In this paper he, like everyone else up to that time, considers the oriental plague to be a variety of typhus fever. He states that MM. Petit and Serres gave to a typhoid outbreak at the Hôtel Dieu in 1812 the name of "fièvre entéro-mésentérique" and that they, like MM. Louis and Chomel, consider it a separate disease. Even in the page of introduction to his memoir M. Gaultier de Claubry shows the bent of his mind, for, after describing typhoid fever as "that grave continued fever, so-called by MM. Louis, Chomel, Bouilland, &c., which has as constant anatomical characters the alteration of the elliptical patches and scattered follicles of the small intestine and that of the lymphatic ganglia of the mesentery," he goes on to say: "We are about to set forth a complete parallel between the two affections (typhus and typhoid fevers) in order to bring out the analogies and the differences, *if there are any*." And so we find that quite early in his memoir at the end of the second chapter he actually concludes with (under the head of "Symptomatology") "*Typhoid and typhus fever present not only analogy but the most perfect resemblance*," and this apparently merely because they both present different forms with different degrees of intensity. Later he tells us that in the two fevers the lenticular eruption is the same but that in typhus it is more abundant and petechial, but that sometimes it is the same in typhoid, and in this latter statement he is quite correct, as the eruption in typhoid may occasionally simulate that of typhus fever so completely as to be indistinguishable from it. I remember well an instance in University College Hospital of a young woman, a patient in one of Sir William Jenner's wards, who contracted *typhoid* fever while in the hospital, and developed the *typhus* rash so completely that one of the best clinical physicians of the time brought his class to see what the typhus eruption was like. The girl was sent to the London Fever Hospital as a case of typhus fever and she died there with ulceration of the Peyer's patches. There was no doubt, therefore, that the girl had typhoid ever. It was known from whom she contracted it and it was quite certain that she could not have contracted typhus ever while in the hospital

Of the intestinal lesions, as of the symptoms, M Gaultier de Claubry concludes that because in typhus fever alterations have sometimes been found in the mucous membrane of the intestines "there is not only a greater or lesser analogy but an *incontestable identity* of organic changes in the two fevers," and he makes this statement in spite of the fact that a little further on he praises the work of M. Lombard of Geneva who says that throughout the six years during which he has studied the subject with the greatest attention he has never seen a single case of typhoid fever in which the intestinal canal did not present after death the lesion of the elliptical patches of the smaller intestine, but that he saw with the greatest surprise that the cases (of typhus fever) at Glasgow and Dublin had no such lesion or affection of the mesenteric glands, and that this was the general experience of the medical men there. As to causes, M. Gaultier de Claubry shows that all authors agree that overcrowding is the cause of typhus fever, but he points out that Louis showed that this could not be the cause of typhoid fever, as only one-eighteenth part of the subjects of it were found to be under that condition, and that most of the cases were among the newcomers to Paris It is a pity that M. Gaultier de Claubry did not pay more attention to this point. If he had he would hardly have concluded his memoir with the sentence: "Typhus fever and typhoid fever are one and the same disease to which it would be convenient to give the name of typhode fever in order to avoid the expression typhoid, which only indicates an analogy of form and the word typhus which frightens people."

The other memoir was by M. Montault. It, like the former one, is a very exhaustive memoir, but, unlike it, commences without any *parti-pris*, as he gives no hint of any preconceived notions, indeed, he says in his introduction that he has "specially shown himself jealous of giving proof of a mind free from preconceived ideas and occupied by an ardent love of truth and guided by observation and reasoning after the well-known precepts of Hippocrates, Baglivi, and Bacon." In the first two parts of his memoir he gives what he calls the history of the two diseases under which he includes causes, symptoms, lesions, and treatment. In the third part he discusses the analogies and differences between them. Persons of all ages are exposed to attacks of typhus, while it is certainly not so for the typhoid fevers (he always speaks of typhoid fevers, not "fever"). Typhoid fever often occurs without overcrowding. Contagion, generally admitted for typhus, is not proved for typhoid fever, which is also more often sporadic than epidemic. He here quotes Hildenbrand as distinguishing completely typhus from the typhoid fevers, because of contagion which is peculiar to typhus. He then points out the differences of the symptoms of the two diseases and says that it is only in typhoid fever that death is sometimes caused by peritonitis following perforation of the intestines, and with regard to the ulceration in the intestines he says that one cannot in typhus fever assign different degrees or various forms to the lesion of Peyer's patches "because it is now probable that this lesion is absent in typhus fever" He also notices the differences in the times of the eruptions: "In the typhoid fevers the special eruption appears from the eighth to the twelfth day; in typhus from the fourth to the seventh day. This eruption which is constant in typhus does not constantly exist in the typhoid fevers. It is more general and more abundant (that is, the spots are more numerous) in typhus. It appears in the nervous period in the typhoid fevers; it disappears on the contrary in the nervous period of typhus. According to M Rochoux it forms a morbilliform eruption in typhus and consists of slight elevations in typhoid fever; according to M Chomel this eruption takes place on the abdomen and chest in the latter disease, whilst in typhus the face and the limbs are especially affected by it; lastly, petechiæ are rare in typhoid fever but very common in typhus." At the end of his memoir he gives a summary of the analogies of the diseases in the form of a table, but although he thus clearly points out the differences between these diseases he does not commit himself to the statement that they are two different diseases He contents himself by stating that Hildenbrand, F. de Sauvages, and P. Frank regarded them as different diseases; that M. Bouillard recognised a "want of identity" at a certain period of the diseases; and that M. Brettoneau had expressed no definite opinion on the matter. It is a great pity that the modesty of M. Montault was so great as to prevent his stating definitely the opinion to which his admirable researches undoubtedly led him. Had he done so it would, perhaps, have prevented the erroneous views of M. Gaultier de Claubry from taking possession of the medical profession in France

A report by M Louis, M. Bricheteau, M. Bouillaud, M Double, M Bally, and M. Andral, on a paper by M. de Larroque on "The Treatment of Typhoid Fever by Purgatives," published in the *Bulletin de l'Académie de Médecine* for 1836, shows how vague was then the knowledge of typhoid fever even among those who knew it best, for they suggest that "the pyrexia, called in France 'typhoid fever,' *may be* nothing else than a gastro-intestinal inflammation," and M. Bouillaud defines it as follows: "Typhoid fever, or adynamic fever, or entero-mesenteric fever, or dothinentérite, or iléo-diclidite, &c., consists in the inflammation of the small intestine and its follicles plus a *typhoid element*, the nature of which is not agreed on." On the other hand, during the discussion M. Rochoux says positively, "Typhus and typhoid fever are two essentially distinct diseases, as M. Petit has proved, and as I have stated in a treatise myself."

At about the same time that Dr. Lombard of Geneva was making his observations which led him to the conclusion that there were "two distinct and separate fevers in Great Britain, one of them identical with contagious typhus, the other a sporadic disease identical with the typhoid fever or *dothienenteritis* of the French, Gerhard and Pennock of Philadelphia were arriving at the same conclusion from observations of an epidemic of typhus which prevailed in that city in the spring and summer of 1836. Both had previously studied the enteric fever in Paris and were familiar with it in their own country. They at once recognised the difference of the new disease, and after a time they were never deceived in their diagnosis." Their observations were published by Gerhard in February and August, 1837. Gerhard maintained that the typhus of Philadelphia was identical with British typhus, and with the gaol, camp, ship, petechial, or spotted fever, and that it was eminently contagious, while, on the other hand, typhoid fever was rarely communicated. He showed that the lesions of Peyer's patches and of the mesenteric glands, invariably present in the latter, were never found in the former, and remarked that English observers erred in regarding the intestinal disease as a mere complication of typhus. He insisted on the marked difference between the petechial eruption of typhus and the rose-coloured spots of typhoid fever, and he showed that a peculiar train of symptoms very different from those of typhus was associated with the intestinal affection, and that the distinctive characters of the two diseases were such as in practice could not allow them to be confounded. To Gerhard and Pennock certainly belongs the credit of first clearly establishing the most important points of distinction between the two diseases. M. Valleix of Paris, in a review published in January and February, 1839, thus alluded to Gerhard's observations: "M. Gerhard établit d'abord un fait bien important, c'est qu'il peut exister, et qu'il existe en effet, concurremment dans le même pays, deux maladies, qu'on peut parfaitement diagnostiquer, et dans lesquelles on peut prédire pendant la vie du malade, les lésions qui seront trouvées après la mort; ce *sont la fièvre typhoide et le typhus* proprement dit."

After this several authorities, especially Dr. Staboroh, Dr. Shuttuck of Boston, M. Valleix, and M. Rochoux, published memoirs pointing out the differences between the two fevers. Of the last mentioned Dr. Murchison says: "He insisted that nothing could be more unlike than the eruptions of the two fevers and that while typhus was highly contagious and generally believed to result from overcrowding the contagious character of dothienenteritis was doubtful and it was independent of overcrowding" (Rochoux, 1840).

On Feb. 6th, 1840, Dr. H. C. Barlow read a very important paper on "The Distinction between Typhus Fever and Dothienentérie" before the Parisian Medical Society, an abstract of which will be found in THE LANCET of Feb. 29th of that year. He insisted that these two fevers were not only different in their lesions but also that "the *fièvre typhoïde* of France is an endemic disease; it is endemic in those localities, as in Paris, where it principally prevails and where the influence of contagion is extremely doubtful and is by many positively denied. The typhus fever of Great Britain and Ireland on the contrary is a highly contagious disease." Further on he says: "I would suggest that two diseases so different in their modes of origin, however nearly in the course of their symptoms they may come to resemble each other cannot be essentially identical. Dothienentérie chiefly attacks those who have only been a short time resident in Paris or in a large city; typhus fever observes no such distinction of persons; the former rarely occurs above the age of 40 years or below that of 10, the latter on the contrary very frequently does. Dothienentérie is at its maximum in autumn and at its minimum in winter. ...... In typhus no such connexion is observed to exist and that disease is often at its greatest height in winter when the former is comparatively rare." He also points out that in typhoid fever "diarrhœa is one of the earliest and most constant symptoms. It usually sets in at the beginning of the disease and continues to its close. It does not appear to be essential, as three fatal cases are mentioned by M. Louis in which it did not occur, neither is there any obvious relation between its amount and the degree of organic lesion which exists, yet its occurrence is almost invariable. In typhus an opposite state prevails and diarrhœa is comparatively rare." After mentioning other differences he describes the eruptions of the two diseases with the greatest minuteness and accuracy. "At about the eighth or ninth day the typhoid eruption, consisting of lenticular, rose-coloured spots, *taches rosées*, appears on the abdomen, back, and chest; it is not an abundant eruption and not always present. The spots are about a line in diameter, regular in form, slightly elevated, and disappear on pressure, but return again. They come out in succession, four days being the average duration of each." After describing the sudamina he adds, "Petechiæ have been chiefly noticed in particular epidemics. They vary in diameter from one to several lines and neither project nor disappear on pressure. Vibices occasionally occur." On the other hand, "in the typhus fever of Great Britain and Ireland the eruption is chiefly petechial, often mixed with vibices, appears earlier, on the fourth or fifth day, sometimes before, and is commonly profuse, the amount of eruption bearing a certain ratio to the intensity and duration of the disease. The duration of dothienentérie may be stated on an average of from 20 to 30 days. ...... The average duration of typhus in 43 fatal cases mentioned by Dr. Reid was 12½ days ...... so that typhus appears to run its course much more rapidly than dothienentérie." He sums up the differences between the two fevers as follows: "A difference in the manner of origin, a difference in the seasons of occurrence, and a difference in the modes of attack; a difference in the series of symptoms, a difference in the external appearance, and a difference in the duration of the diseases; a difference in the ages at which they occur, a difference in the sexes in which they principally prevail, and a difference in the mortality which they respectively occasion. While the great and crowning difference of all is the existence of a particular anatomical lesion in one, and the absence of any obvious anatomical lesion in the other. Surely two diseases which differ in all these particulars cannot be identical." No wonder that Dr. Murchison says: "This paper has received less attention from subsequent writers than it deserves." I will go farther than that and will say that although previous writers had foreshadowed the differences between the two diseases, and although some of those writers whom I have mentioned had gone so far as to declare that the two diseases were different from one another, Dr. Barlow was the first man to give a detailed and complete account of the differences between the two diseases and to establish once and for ever that they are entirely distinct from one another. The only important fact in connexion with the two diseases that he does not point out is the difference in their *causes*.

In the same year—viz., on April 16th and 23rd, 1840—Dr. A. P. Stewart read a paper, also before the Parisian Medical Society, entitled, "Some Considerations on the Nature and Pathology of Typhus and Typhoid Fever applied to the Solution of the Question of Identity or Non-identity of the Two Diseases." This paper is an admirable summary of the state of knowledge on the subject at the time and contains an excellent description of the two diseases and their differences. He alludes to the cause of typhoid fever, of which he says: "With regard to the producing cause of typhoid fever all is vague and uncertain, ...... but what chiefly concerns us to know is whether the conditions we have seen to be so powerful in the production of typhus are the same, or anything like the same, in regard to typhoid fever. Exactly on this point Louis remarks: 'No more can the dwelling in places, low and inhabited during night by too great a number of individuals, figure among the causes in question, one-eighteenth only of the patients being in that condition,' and he concludes from a comparison of all the assigned causes with the facts ascertained by himself in these remarkable words: 'The deepest darkness, then, prevails regarding the causes of the affection under consideration.' Chomel likewise uses the same words in beginning his third article: 'The causes of typhoid fever are wrapped in the greatest obscurity.'" As to Dr. Stewart himself he merely says without hazarding any decided conclusion on a point so keenly debated: "I would simply direct attention to the differences as regards the probable origin and propagation of the two diseases which the foregoing facts appear to establish and also to the interesting question whether, if typhoid fever really depends on and is propagated by a specific poison, that poison is or is not generated under the same circumstances as the infection of typhus." So that as far as the cause is concerned Dr. Stewart does not advance us at all, neither does he venture to say that typhoid and typhus fevers are distinct diseases, for he sums up the matter as follows: "On a review, then, of all that has been advanced, it would appear that typhus and typhoid fever present important differences, as regards their probable origin, their approximate causes, their course, many of their symptoms, their diseased appearances, and the treatment applied to each. Are they, then, identical, or are they not? I feel that it would be presumptuous in me to hazard a direct reply; nor do I demand an answer in the affirmative merely on the faith of what I have stated. All I can ask or wish for is careful, extensive, and minute inquiry without prepossession or love of system, and a satisfactory solution must soon be arrived at." So that he does not really lead us as far as Dr. Barlow had already done.

In the year 1841 a work entitled "Traité de l'Entérite Folliculeuse (Fièvre Typhoide)," by C. P. Forget, Professor of Clinical Medicine at the University of Strasburg, was published in Paris, consisting, in fact, of lectures previously given by that physician to his students, to whom it is dedicated. (The preface is dated November, 1840.) In these lectures he speaks of the *essential distinctions* between typhus and typhoid fevers, saying that they have only been determined within recent times. He gives Hildenbrand the credit of being the author who had done more than any other to point out the specific nature of typhus fever, but he does not agree that the other fevers from which Hildenbrand distinguishes it are necessarily non-contagious. He then discusses the views of M. Gaultier de Claubry and other authors who maintain that typhus and typhoid fevers were the same diseases. M. Forget excuses himself for quoting so many authorities by saying that he has not had the sad privilege of observing epidemic typhus. He is evidently much impressed with the views of M. Gaultier de Claubry and admits that it is possible that many of the grave febrile affections referred to may be identical, but he defines his own object as follows: "That which I profess to show is that our *sporadic* typhus *nostras, typhoid fever*—in a word, the grave continued fevers of our country—are, and certainly always have been, associated with follicular enteritis. *Let this be well understood. We do not profess to talk of that which we have not seen* (i.e., of typhus fever); it is follicular enteritis, commonly called typhoid fever, which is going to occupy us exclusively." He is perfectly clear about the fact that the disease has this special lesion and he gives the following definition: "Follicular enteritis is defined by itself—that is to say, that the lesion which names it is its fundamental character. Follicular enteritis is the inflammation of the intestinal follicles, as pneumonia is the inflammation of the lung." And again: "Follicular enteritis is a material fact, as pneumonia, hepiditis, cancer, variola, &c. Why, then, should we refuse to make a disease of it? ...... What we have to do here is to establish the reality of follicular enteritis as an evident morbid fact; it is to recognise its right to a place in the catalogue of diseases.[3] For him, among several alterations in the intestinal canal those of Peyer's patches are the most characteristic, and he describes them in great detail, referring to the observations of Bretonneau, Louis, Chomel, and Montault on perforation of the intestine in this disease. Although he mentions the *taches rosées* he evidently does not consider them as especially characteristic of the disease any more than the sudamina or the petechiæ which he also mentions. As to the cause of the disease, while he considers that it may be produced by foul air and decomposing foods, he says that the causes "sont très variables et n'offrent rien de spécifique." It is evident, however, that he attached some importance to foods as a possible means of conveying the disease, for he says: "Is it not, indeed, singular that some would deny that food, for instance, has the power of directly producing follicular enteritis, when they attribute to it without difficulty gastritis, colitis, and villous enteritis itself?" After quoting a number of other authors, some of whom maintain that the disease is contagious and others that it is not, he gives his own opinion as follows: "As for me, a pupil of the Paris School, I have denied the contagion until after my removal to the country, as indisputable facts showed me that typhoid fever can affect persons who stay near sick persons. Whether it is by the inoculation of a specific virus (contagion) or by inspiration of air vitiated in any other manner (infection) I do not know; but this is positive, that the disease *is communicated* in certain circumstances somewhat rare and still undetermined." Th sentence, I think, expresses the view that is held mos generally now. However, he in fine concludes "that ther is nothing invariable and essential in the causes of follicula enteritis; nothing essential and invariable except follicula enteritis itself."

Such was the position when Dr. William Jenner (afterwards Sir William Jenner, Bart., G.C.B., one of the ablest Presidents the College ever had) undertook the investigation of the question. Having been resident medical officer of the London Fever Hospital he had had an excellent opportunity, of which he made the best use, of making observations on cases of both typhus and typhoid fevers, and in 1849 his paper "On the Identity or Non-identity of Typhoid and Typhus Fevers" appeared in the *Monthly Journal* and was published in a separate form by John Churchill in 1850. In the introduction to this paper he points out "that with few exceptions British physicians have laboured to prove that typhoid and typhus fevers are identical. The results obtained by this analysis justify the assertion that they are essentially distinct diseases." He commences by stating the differences between scarlet fever and small-pox and in a masterly manner proceeds in his paper to show that similar differences are observed between typhoid fever and typhus fever. "We assert that small-pox and scarlet fever are different diseases for the five following reasons: 1st. In the vast majority of cases the general symptoms differ. 2nd. The eruptions, the diagnostic characters if present, are never identical. 3rd. The anatomical character of the one is never seen in the other. 4th. Both being contagious diseases, the one, by no combination of the individual peculiarities, atmospheric variations, epidemic constitutions, or hygienic conditions, can give rise to the other. 5th. The epidemic constitution favourable to the origin, spread, or peculiarity in form or severity of either has no influence over the other excepting that which its exercises over disease in general." With regard to the third of these he explains as follows: "By the anatomical character of a disease I intend to signify that lesion or those lesions of structure which are the invariable concomitants of a disease if it has continued for a given time, which time must be determined by a separate series of observations for every distinct affection. The anatomical character is not, be it remarked—and this is of immense importance—necessarily the cause of the disease, for it may be merely a symptom; but then, if the disease be not cut short by death it is an invariable symptom." Jenner saw that the crucial question was the determination of the facts with regard to the intestinal lesions. He remarks: "London alone of all the cities of Europe, from the fact of fever, with and without intestinal disease, being almost constantly present within its bounds, afforded a field for observation capable of setting the vexed question at rest. In Edinburgh, writes Dr Christison, the intestinal lesion is seen often enough only to prevent physicians being ignorant of its characters. In Dublin it appears to be equally unfrequent, while on the continent fever without lesion of the agminated glands is so rare that many eminent practitioners have doubted the existence of such an affection. The London Fever Hospital, by collecting within its walls cases of continued fever from all parts of the great metropolis, offered peculiar facilities for its study." During two years he made notes of nearly 1000 cases of acute disease, of which 66 were fatal cases of continued fever which were examined by him after death. This was necessary, as it was essential that the presence or absence of the intestinal lesion should be demonstrated. Of the 66 cases he found that in 23 the disease of Peyer's patches existed. These were cases of typhoid fever. In the remaining 43 the agminated glands, so far as the unassisted eye could determine, were in a healthy condition and these were cases of typhus fever. He then describes with the greatest minuteness the differences in the symptoms of the two diseases and concludes by combating two assertions that had been put forward "to account for the differences in symptoms which existed in continued fever with and without entero-mesenteric disease." 1. That typhoid fever is merely typhus fever complicated with lesions of a particular organ and it is therefore to be expected that certain symptoms referable to, and dependent on, that lesion will be present and so far modify the symptoms of the disease. He maintains, on the contrary, that the general symptoms of the two diseases in the cases he examined differed widely, "such differences having no apparent connexion with the local affection but being probably, like it, dependent on some common cause acting on the whole system simultaneously. Thus the remarkable differences in the kind—no small amount —of the rash of the two diseases, and the tendency to local inflammations, to erysipelas, and to ulceration, observed in the cases of typhoid fever here analysed, cannot with any show of reason be considered to have been dependent on the disease of Peyer's patches—i.e., in the same way as the abdominal signs undoubtedly were. The fact also that the duration of typhoid fever, and even of fatal cases of it, is considerably greater than is that of typhus fever also struck me very forcibly. The short comparative duration of the cases of typhus fever here considered is another remarkable point of difference, totally inexplicable by the hypothesis that typhoid fever is typhus fever with intestinal ulceration. Had the cases eventually recovered it might have been said that the intestinal lesion prolonged the disease in the cases of typhoid fever, but that all the fatal cases of fever, with a local lesion of so severe a nature as that recorded to have been present in the cases of typhoid fever, should have had a much longer course than all those other fatal cases of fever in which no organic change of structure could be detected after death appears to me inexplicable on the supposition that the former is simply the latter disease, with this serious lesion superadded. Let me repeat, by this hypothesis, we are asked to imagine that death is retarded in fever by extensive ulceration of the small intestines and enlargement, softening, and even suppuration of the mesenteric glands. Surely it behoves the supporters of such a statement to bring forward cogent proofs of the identity of the specific cause of the two affections ere they ask us to admit its truth." After pointing out other important differences he adds: "Thus tried by facts—i.e., by recorded symptoms and lesions—the assertion that typhoid fever is merely typhus fever with abdominal complication is completely refuted." 2 But another mode of explaining the differences which exist between the two diseases has been given—i.e , that the differences observed depend on variations in the epidemic constitution. These cases afford a complete answer to this assertion, for a majority of the cases here analysed of both diseases were observed during the same epidemic. "The cases of typhoid fever—which disease is rarely absent for a fortnight from the wards of the hospital—preserved their symptoms unchanged and presented the same lesions whatever the epidemic constitution that prevailed; the same is true of typhus fever. Cases of the latter disease are also rarely absent from the wards of the same institution. It is there common to see the patients occupying beds side by side and presenting respectively the well-marked characters of either disease. If, I repeat, the two affections were really the same disease, then the same epidemic constitution ought to have impressed on both the same general features, implanted in both the same local lesions, and given to both the same tendency to cadaveric change, and this allowing for all the modifying influence which the accidental presence of the abdominal lesions in the one and the absence from the other group might have occasioned. The analysis of every symptom and every lesion shows that the two affections were not thus assimilated by the prevalence of any particular epidemic constitution. But if this epidemic constitution, by any stretch of the imagination, could be supposed to change from week to week, to cause the case attacked to-day to have typhus fever, the individual who takes the disease to-morrow to have typhoid fever, still it could not account for the fact, as well established as any fact in medicine, that typhoid fever rarely, if ever, affects persons more than 50 years of age, while age exerts little influence in determining the occurrence of typhus fever. Thus, then, the assertion that typhoid fever is merely typhus fever modified by the prevailing epidemic constitution is as irreconcilable with facts as that the former disease is simply the latter with abdominal complication " He then repeats the distinctions between small-pox and scarlet fever and concludes: "If, then, the above are the grounds—and after mature deliberation I am able to assign no others—for the separation of small-pox from scarlet fever, I think it is indisputably proved that typhoid fever and typhus fever are equally distinct diseases—not mere varieties of each other, but specially distinct—specific distinction being shown in typhoid and typhus fevers, as in small-pox and scarlet fever, by the difference of their symptoms, course, *duration*, lesions, and *cause*."

---

[3] He thus gives the disease the name of what he regards as its important and characteristic lesion, calling it "follicular enteritis"—even a worse name for it than "enteric fever."

Thus Jenner, as all who knew him knew, always had the courage of his opinions. He was not afraid, as some others before him had been, to state definitely, succinctly, and without circumlocution, the conclusions to which his investigations had led him, even though those conclusions were at variance, as he himself says, with the great majority of medical opinion at the time both in this country and on the continent. But this was not all. On Dec. 11th, 1849, Dr. William Jenner read a paper before the Royal Medical and Chirurgical Society entitled "On the Identity or Non-Identity of the Specific Cause of Typhoid, Typhus, and Relapsing Fever." For this purpose he analysed the cases admitted into the London Fever Hospital during the years 1847, 1848, and 1849, and the summary of his results is as follows: "In 1848 one-fourth of the cases admitted into the hospital had typhoid fever; while from 34 foci of typhus fever, yielding 101 cases, there was brought to the hospital once only a case of typhus fever and a case of typhoid fever from the same house; and during the same time among five localities affording nine cases of typhoid fever, one locality only ...... yielding a case of typhoid and one of typhus fever. That in 1849, although 18 foci of typhus fever yielded 51 cases and four foci of typhoid fever afforded 10 cases, not a single example of the two diseases being received into the hospital from one house occurred." And he concludes: "The facts contained in this paper appear to me to prove incontestably, so far as induction can prove the point, that the specific causes of typhus and typhoid fevers are absolutely different from each other....... I have throughout this paper expressed myself as if the specific cause respectively of typhoid fever, typhus fever, and relapsing fever was an influence emanating from the bodies of those affected with either disease. With respect to the contagious nature of typhus fever, I know no one who entertains a doubt. If typhoid fever be contagious it is infinitely less so than typhus fever. My experience leads me to regard it as contagious. Those who believe typhoid fever to be non-contagious while they admit the contagious nature of typhus fever cannot for a moment doubt the difference in the specific causes of the diseases. It would not, it ought to be observed, have weakened the force of the facts adduced if I had regarded these diseases as non-contagious, because the question here considered is not how the individuals respectively got the disease, but if the same cause, whether contagion or any other, can produce typhoid fever, typhus fever, and relapsing fever."[4]

Thus Dr. Jenner carries us, at any rate, one step farther. He not only asserts, as Dr. Barlow and others had done, that the two are distinct diseases, and proves it up to the hilt, but he also proves that they must have essentially different causes.

Dr. Murchison read a paper before the Royal Medical and Chirurgical Society on April 27th, 1858, entitled, "Contributions to the Etiology of Continued Fever, or an Investigation of Various Causes which Influence the Prevalence and Mortality of its Different Forms." In this admirable paper, describing the results of his observations at the London Fever Hospital, he establishes the following important points (besides many others) which I will give in his own words:—

1. Typhus and relapsing fever are quite independent of the season of the year, whereas typhoid fever is almost invariably most prevalent during autumn at the time that diarrhœa is most common, and it has been observed to be specially prevalent in seasons remarkable for their high temperature.

2. Sex has no influence over the prevalence of continued fever nor over that of any of its forms.

3. Typhoid fever is pre eminently a disease of childhood and adolescence, at which periods of life we know that there is a marked proneness to enteric affections. Less than one seventh of the cases of typhoid are above 30 years of age. Typhus and relapsing fever exhibit no predilection for youth—of typhus one half, and of relapsing fever one-third, of the cases are above 30.

4. Typhus and relapsing fever appertain exclusively to poverty and destitution, and seldom or never occur among the wealthy except from direct contagion. Typhoid fever attacks both poor and rich without distinction.

5. In large cities typhus and relapsing fever are for the most part limited to those localities remarkable for the overcrowding of their

---

[4] Transactions of the Royal Medical and Chirurgical Society vol. xxxiii., 1850.

inhabitants, and in country districts they are seldom or never met *with except as the result of direct importation* Typhoid on the other hand, occurs alike in the centre and suburbs of cities, in the crowded houses of the poor and in the spacious mansions of the great, and also in isolated houses and hamlets in the country, without any traceable sources of contagion

6 When fever breaks out in a house or locality it seldom or never happens that some of the cases are typhus and others typhoid, but typhus and relapsing fever occur not unfrequently together

7 Overcrowding with deficient ventilation and destitution appear to be the essential causes *of typhus and relapsing fever and to be capable* of generating them *de novo*, [?][5] while there is no evidence that they *have any such influence over the production of typhoid fever*

8 There are many circumstances which tend to the belief that the emanations of decaying organic matter or organic impurities in drinking water or both of these causes combined are capable of generating [?] typhoid fever, but there is no authenticated evidence whatever to prove that such causes can give rise to typhus or relapsing fever

9 Typhus is eminently contagious Typhoid fever is also contagious but in a more limited degree and possibly through a different medium Again, typhus has in no instance been proved to communicate typhoid, nor typhoid to communicate typhus An attack of either confers an immunity from a future attack of itself, but not of the other

10 In all of the fevers there is not much difference in the mortality of the two sexes

11 *The mortality from* typhus is *greater among* the very *poor* than among those in better circumstances Typhoid fever appears to be *equally mortal in all classes*

12 Typhus and relapsing fever are strongly assimilated in the causes which give rise to them, *if they be not mutually convertible diseases* Typhoid fever on the contrary appears to be a perfectly distinct affection dependent upon totally different causes

It is very interesting *to note* that in the course of this paper Dr Murchison observed "that out of 10 *cowkeepers* admitted with fever in nine the fever was typhoid," and also that he "*ascertained that in several instances* patients entered as 'labourers' had been *employed in the drains*, in every such case the fever was typhoid" Of the patients admitted to the fever hospital "most of those who may have been supposed to have occupied the best conditions have been admitted with typhoid fever Thus the proportion of family servants admitted with typhoid has been three times that of typhus, of policemen six times, and of shopmen more than double On the other hand among '*paupers*' typhus and relapsing fever taken together *have been eight times as frequent as typhoid, and of* 64 'vagrants' admitted with fever in not a single instance was this typhoid" Again "Typhus fever among the rich, *except* as the *result* of *contagion*, is excessively rare, while cases of typhoid originating without any traceable contagion are far from uncommon I think, then, it may be concluded that typhus and relapsing fever are for the most part confined to the poor, but that typhoid fever makes no distinctions between one class and another" He shows that typhus fever prevails in overcrowded localities, whereas "a careful study of a great number of recorded outbreaks of fever in country towns and villages throughout England has convinced me that these outbreaks are almost invariably typhoid It is also a fact worthy of notice that several instances have come under my own observation of typhoid fever making its appearance in an isolated house in the country, in a family living in easy circumstances without any traceable source of contagion, of its attacking several individuals, and then disappearing without *spreading beyond that house* Dr Bartlett also makes similar observations as the results of his experience in America On the other hand, I am acquainted with no instance of typhus or relapsing fever *originating in* this way" He agrees with Dr Jenner that typhus fever and typhoid fever originate from *different foci of infection* "In no single *instance during* the 10 years have I *met with a case* of typhus and typhoid admitted from the same family, or even from the same house except (and the exceptions have been *only one or two*) *after the lapse of many* months or even years He then gives a number of cases in which typhoid fever was associated with "putrid emanations from *decomposing organic matter in drains*, cesspools, churchyards &c., and organic impurities in drinking water." These cases (actually dating from 1747 onwards) included the *celebrated outbreak in the* Westminster School and Abbey Cloisters in 1848, known as the Westminster fever, which attacked 36 persons, all of the better class, with three *fatal cases* A very bad *smell had* been complained of in the houses where these cases occurred during two or three days of very hot weather and 'it was found that the disease followed very exactly *in its* course the line of a foul and neglected sewer in which fæcal matter had been accumulating for years without any exit and which communicated by direct openings with the drains of all the houses in which it occurred" He also relates that towards the end of 1852 an outbreak of typhoid fever took place at Croydon, which was investigated by a committee of the Epidemiological Society consisting of Dr. A. P. Stewart, Dr Jenner, and Dr Sankey, and which was found to be caused by fæcal emanations of various kinds *and* also by contamination of the drinking water And at the end of this evidence he concludes "that typhoid fever is often, if *not always, generated by the putrid emanations from drains* and other sources, or by decomposing organic matter in drinking water" While, then, Dr Jenner proved that typhus fever and typhoid fever must proceed from different causes, Dr Murchison took us a step further and showed in the most masterly manner that typhoid fever was not produced under circumstances of overcrowding as it was well known that typhus fever was, but that although spread partly by direct contagion it was chiefly spread by means of foul emanations from sewers and drains and the pollution of drinking water with foul organic matters

I may here insert the opinion of the great French clinician, Trousseau, who says "Dothienentérie is a general disease, acute, *febrile*, very akin *to the eruptive fevers of which* we have spoken and with which it offers more than one striking analogy" He also says "La contagion de la dothienentérie est *incontestable*"

In 1862 Dr Murchison issued his "Treatise on the Continued Fevers of Great Britain," and in 1873 the second edition of it appeared In this work he gives an excellent historical account of typhoid fever which he calls enteric or pythogenic fever, the last name being suggested by him as an expression of what he believed to be the origin of the disease This is shown in his opening lines wherein he defines it as "an endemic disease generated and propagated by certain forms of decomposing organic matter" This treatise is so well known that I need not summarise it. I will merely give his own summary of its etiology, which is as follows —

1 *Enteric fever is either an endemic disease or its epidemics are* circumscribed 2 It is most prevalent in autumn and after hot weather 3 *It is independent of overcrowding and attacks rich and* poor indiscriminately 4 It may be generated independently of a previous case by *fermentation of fæcal* and *perhaps other forms of* organic matter 5 It may be communicated by the sick to persons in health but even then the poison is not, like that of small pox given off from the body in a virulent form but is developed by the decomposition of the excreta after their discharge 6 Consequently an outbreak of enteric fever implies poisoning of air, drinking water, or other ingesta with decomposing excrement

With regard to No 1, I will note that typhoid fever epidemics are often very widely spread Nos 2 and 3 are universally admitted and I will say no more about them Nos 4, 5, and 6 imply the view so strongly held by Dr Murchison that the disease is caused by a poison produced by decomposing fæces, which poison is not contained in the fresh excrement, and therefore amount to a denial of the fact that the *disease is produced by an organism* which is transmitted from one case to another This view, like that of M Gaultier de Claubry (who proclaimed the identity of typhus and *typhoid* fever) in France, obtained a great hold on the medical profession in this country and has been with considerable difficulty eradicated

In 1873 Dr William *Budd produced his work* on "Typhoid Fever, its Nature, Mode of Spreading, and Prevention,' in which he maintains that *it was proved long ago* that "typhoid fever is in its *essence a contagious or self-propagating fever*,' and he adds 'It is scarcely to the credit of the medical profession that this great truth should still be disputed" He then quotes *a number of authors who did dispute it*, but mentions 'Sir Thomas Watson who in his admirable work on the Practice of Medicine has not only lent his powerful sanction" to *the doctrines of the contagious origin and mode* of spread of typhoid fever, "but has given an exposition of them in that terse and lucid style of which he is so great a master, and I *may add that in Sir Thomas Watson's small* work on the Abolition of *Zymotic* Diseases, published in 1879, he says referring to typhoid fever, "When we reflect how readily this *origin of the disease* (*through water or milk*) may escape suspicion or may elude detection even when suspicion has been roused, we find continual reason for distrusting the argument *for the spontaneous development of* the disease based upon the difficulty of tracing the contagion to any conceivable source For my own part I cannot but deem this argument *altogether worthless*' *In his work Dr* Budd proves up to the hilt that the disease is directly contagious or communicable from one person to another and he gives the most remarkable examples of infection by direct contagion. As to this being one of the contagious fevers he well says: "The existence here, as in the other contagious fevers, of a latent period after the occurrence of the infection, the exemption conferred by one attack against any future attack, and, lastly, the immunity of large numbers of persons who though freely exposed to the fever poison yet remained proof against it, are characteristics of which the significance cannot be doubtful." He gives a graphic comparison between small-pox and typhoid fever. Each has a latent period; in each one attack protects against any future attack in the vast majority of instances, "so that if typhoid fever happens only once in life it is, as in small-pox, simply because the typhoid-fever poison *cannot grow again* in a body in which it has once bred," and after pointing out that what we actually *see* in small-pox takes place in the diseases of the same group, including typhoid fever, he sums up: "*The living human body, therefore, is the soil in which this specific poison breeds and multiplies, and that most specific of processes which constitutes the fever itself is the process by which the multiplication is effected.* As in small-pox, so in typhoid—to spread by this mode of reproduction is not only a characteristic but the *master*-fact in its history." For him, "*all* the emanations from the sick are in a certain degree infectious At the same time it is one of the principal objects of this work to show that what is cast off from the intestines is incomparably more virulent than anything else." Outbreaks of typhoid fever such as he describes, according to his view, "never occur except under one condition—that is to say, where no sufficient provisions have been made for preventing the discharges from the human intestine from contaminating the soil and air of the invaded area. Where these provisions are wanting the most spacious rooms and the freest internal ventilation afford no certain security against the spread of the fever." Finally: "Like malignant cholera, dysentery, yellow fever, and others that might be named, this is one of the great group of diseases *which infect the ground*. Hence the quasi-miasmatic character attaching to them all, which has misled so many observers as to their true mode of spreading."

---

[5] The bracketed interrogation mark after the words *de novo* in this paragraph is mine, as is that also in paragraph 8 following the word generating

It is not too much to say that in this admirable treatise Dr. Budd proves his contention up to the hilt, sufficiently, at any rate, to convince the highly-trained scientific mind of Professor Tyndall who, in a powerful letter to the *Times* dated Nov. 6th, 1874, referring to one of the outbreaks described by Dr. Budd, says: "How could a disease whose characteristics are so severely demonstrable have ever been imagined to be non-contagious? How could such a doctrine be followed out, as it has been to the destruction of human life?"

In March, 1874, I read a paper before the Epidemiological Society "On the Alleged Spontaneous Production of the Poison of Enteric Fever," from which I may be allowed to make the following quotations:—

> We are, however, told that the intestinal discharges from a patient suffering from enteric fever are not infectious when fresh and only become so after decomposition has set in, and in proof of this it is advanced that medical attendants do not take it from the patients, that nurses do not get it, and that other patients in the same ward, although using the same utensils, scarcely ever take the disease. Now it must be admitted that such cases are uncommon, though they are by no means unknown; indeed, I find that while Murchison, on page 461 of the second edition of his "Treatise on Continued Fevers," says, "I have never known or heard of a case where the fever has been communicated to the medical attendant not residing in the infected house," he says (p. 469) of Putegnat, who thought he had caught it from making a post mortem on a case, "It is true that he was seized a few days after the autopsy, *but he had attended both the patient and her mother during their illness*"; so that on one page we are told that the fever is not communicable because medical men do not get it from their patients, and 10 pages farther on we find that the fact that a medical man got it after making an autopsy is considered to be no proof that the body was contagious, because he had been attending the patient and her mother during their illness!
>
> But is it proved in any sense of the word that the fresh fæces of a patient do not contain the poison of the disease? Certainly not. All that can be deduced from the facts is that they do not give out the poison in any considerable quantities into the air, and this makes it probable, without reasoning from mere analogy, that the poison consists, like the active principle of vaccinia, of solid particles, which do not evaporate from liquids in which they are, but may be carried up mechanically by the volumes of gas given off when such liquids ferment, or after the evaporation of the liquid may be desiccated and blown about; thus we see how it may be that the fæces have come to be regarded as more poisonous when decomposing than when fresh, or even as developing the poison during decomposition.
>
> I say that there is not one iota of proof that the fresh stools do not contain the poison of the disease, and that to say so is like saying that a solution of sugar of lead or of corrosive sublimate, scented with, say, attar of roses, is not poisonous, because you can stay in the same room with it without being poisoned, or that a vessel of vaccine matter does not contain the active principle of vaccinia, because you can handle it without being affected by vaccinia.
>
> I can understand the position taken up by Andral who "declared that he had never seen it exhibit the slightest contagious character", or by Dr. Stewart who wrote in 1840, "In no case, though questioned with the greatest care, either in Scotland or in the hospitals of Paris, have I ever found the disease referred to contagion."
>
> I can understand that taken up by Trousseau, by Dr. Budd, and by others, who maintain that the disease is essentially contagious. But I cannot understand the anomalous, as it seems to me, position of those who in effect say, "Well, it's not a contagious disease, but as you've certainly brought forward some cases in which it appears to have been communicated from man to man, we must admit that occasionally it is contagious."
>
> That it is contagious, and most virulently so, I have not the slightest doubt; but I quite understand what those mean who say it is not: they mean that if you attend upon a patient suffering from enteric fever you are not likely to get it, while if you attend on one suffering from typhus or scarlet fever you are very likely to do so, unless you have had the disease before; they do not consider that this fact is not due to a difference in the contagious nature of the disease but to a difference in the form in which the poison is excreted from the patient, most of it being in the one case given out into the air which the attendants breathe, while in the other most of it is swamped in a mass of liquid which is removed as soon as possible. Those accustomed to small-pox, scarlet fever, and the like, of course said that enteric fever was not contagious when it was first brought to their notice, and there is no doubt that it is, under ordinary circumstances, very slightly so in their limited sense of the word; but that is not what is meant by those who now deny that, except under certain circumstances, it is not communicable from one person to another.
>
> When we point to undoubted instances where a person suffering from enteric fever has taken it into a place where it was before unknown, but in which it has spread from that person, it is at once admitted "that there are unequivocal cases of enteric fever propagated in the manner described," but we are told that "such occurrences are exceptional, and that *the number of cases where the disease is introduced into a new locality without spreading far exceeds that in which it is propagated*," which means that the expedients adopted to get rid of the excretal matters were, in the cases observed (probably chiefly in large towns), generally sufficient to ensure the immediate removal of the infected fæces from the premises in a short time.
>
> But I would put the facts in another light and would say: We see in how many cases we can prevent this disease from spreading; we can almost always point out the reason why it spreads in a house or town when it does so, and we ought to prevent its spreading much more frequently than we do.
>
> Are we, then, able to trace every case of enteric fever to a previous case? Certainly not; and it would be very wonderful if we could. When we consider that a person suffering from this disease may go about for weeks, leaving the poison in several different places every day; that he may go about his work until so prostrate that he goes to bed to die; that he may fall down dead from perforation of the intestines without the disease having been recognised; that the poison which he has left in so many different places may be distributed broadcast in water, milk, sewer air, or some other vehicle,—when we consider all these things, we may well wonder, not that we are often unable to trace the disease to infection from a previous case, but that we are so often able to do so. From the fact that we are able so frequently to point out the source whence the contagion has been derived, and to trace it to a previous case, we have at any rate a strong presumption in favour of the view that when isolated cases occur, and there appears to be no connexion with previous ones, the fact is that we are unable to trace any such connexion, and it is clear from the nature of the disease that this must very frequently be the case; and, moreover, we have no right to assume that we even yet know all the methods by which the poison of this disease may be conveyed. It is only comparatively recently that milk has been recognised as a vehicle of contagion, and there may be, and probably are, many other media of which we have not yet any knowledge, by which the poison is conveyed from place to place.
>
> It is clear that in towns, large and small, where strangers are continually coming and going, and where commodities of various kinds are brought from outside, and houses are connected with public sewers, it is not merely "difficult," as Dr. Murchison says, but on the face of it *impossible*, "to exclude the possibility of contagion," and so we may dismiss such cases at once. But then it must be allowed that many instances are on record where outbreaks of this disease have occurred in isolated villages and country houses, and where every effort has failed to trace any importation of the poison. It will be found on reading the published accounts of such cases that the possibility of importation in a variety of ways has been overlooked. A great many of them are cases of schools or other places where a number of people are collected together. No number of such cases would be sufficient to warrant the assumption that the disease arose *de novo* in any one of them. In most of the other instances we find that old cesspools, stopped-up drains, &c., have been disturbed, or have drained into wells, or leaked into the basements of houses. How are we justified in assuming anything more than that the filth contained the poison of the disease? How can we pretend for a moment to say that we have excluded the possibility of its introduction into masses of excrement which have been going on accumulating perhaps for years? The thing is manifestly impossible. And when we consider how many persons—visitors, servants, and vagrants—go to and from "isolated country houses," and their premises (stable-yards, &c.), we shall be disposed to hesitate before saying that we have excluded all possibility of importation.
>
> I must confess that these considerations prevent my accepting any of the cases on record as cases where non-importation has been proved, and I cannot therefore accept the dictum that the disease "may be generated independently of a previous case by fermentation of fæcal and perhaps other forms of organic matter." Were this true, would not the disease be much more prevalent? How is it that a house or town may be in a condition eminently suited for the existence of this fever, as shown by the fact that when a case is imported the disease ~~spreads, and often becomes~~ a severe epidemic, and yet no case is heard of there for many years, until the importation takes place? One town that I have already alluded to is a most filthy, overcrowded place; it has been several times decimated by cholera, but no enteric fever

occurred there for many years, until one day a case was imported, and the disease spread like wildfire, showing that the conditions for its existence were most favourable; and such instances might easily be multiplied were it necessary. Besides, we know very well what disease sewer air causes—it causes diarrhœa. Over and over again have I seen whole households prostrated with diarrhœa, when air from a foul sewer has leaked into the house, or air from a blocked up sewer or soil pipe has found its way into the drinking water cistern through the waste pipe and has fouled the water.

I therefore maintain that foul air contaminated by decomposing animal matters is capable of producing mere diarrhœa and that when it produces enteric fever it contains the poison of that disease, and that the arguments adduced to prove that this poison can be generated from ich decomposing matters independently of a previous case of the isease are inadequate to do so, that in many of the cases where non-mportation is supposed to have been all but proved it has not been ven rendered a fair presumption, and therefore that in the present tate of our knowledge we are not justified in saying that the disease ver arises *de novo*.

The correctness of the views maintained in the above paper has now been demonstrated by the discovery of the *bacillus typhosus*.

ABSTRACT OF

# Three Lectures

ON

# THE PULMONARY CIRCULATION, MORE PARTICULARLY IN RELATIONSHIP TO VARIATIONS IN CARDIAC ACTIVITY.

*livered before the Royal College of Surgeons of England on Feb. 17th, 19th, and 21st, 1902,*

BY T. G. BRODIE, M.D. LOND.,

RIS AND GALE LECTURER; DIRECTOR OF THE CONJOINT LABORATORIES OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, AND LECTURER ON PHYSIOLOGY AT THE LONDON SCHOOL OF MEDICINE FOR WOMEN.

PREVIOUS workers upon the circulation through the lungs have mainly confined their attention to a study of the pressure changes in a pulmonary artery or vein in comparison with the pressure records in the aorta, and from these operations they have drawn conclusions as to the general variations of the circulation through the lungs. The close relationship of the two sides of the heart to the pulmonary vessels renders it, in most cases, a matter of considerable difficulty to decide, from observations of pressure changes alone, whether or not any active change has taken place in the pulmonary vessels. Hence the observations forming the subject-matter of the main portion of these lectures have been conducted by Dr. W. E. Dixon and myself during the past two years and took their origin from the application of another method—the plethysmographic—to the lung. This method has already proved of very great value in the study of the circulation in organs on the systemic circulation and has also proved a most valuable means of studying the circulation through the lungs under various conditions.

The operation consists in first exposing the lower lobe of the lung by the resection of two or three ribs. The lobe is then thoroughly freed up to the root of the lung, and if the object is to study the vascular changes one of two methods is adopted. In our first experiments we prevented the entrance of air into the lung by gently compressing it before inserting it in the oncometer. In this way the lobe does not expand with the ordinary air pressure used in artificial respiration. In a second series of experiments we first distended the lobe to its normal extent and then plugged the bronchus leading to the lobe by a pledget of cotton-wool soaked in vaseline, inserted by means of a long probe passed down the trachea. The lobe was then fixed in the oncometer and its variations in capacity recorded by connecting the oncometer to a piston or bellows-recorder. We have always simultaneously registered the aortic pressure by a mercury manometer. The advantages of the method lie chiefly in that it gives us at once a record of the changes in amount of blood contained within the lungs, thus showing immediately the production of an anæmia or congestion of the lung capillaries. By combining the information thus gained with the pressure changes in the four chambers of the heart we can often definitely determine the nature of the change that has been produced in a more certain way than can ever be obtained from records of the pressure changes only.

Variations in the flow of blood through the lungs may be caused by changes in the activity of the right heart or in the resistance offered by the pulmonary vessels and capillaries, and to this extent the problems offered for our study are similar to those so fully studied in the systemic circulation. Whereas, however, variations in the activity of the right heart produce but small effects upon the flow through the systemic capillaries, unless those changes be very pronounced, variations in the working of the left heart produce at once marked changes in the blood contents of the lungs. As Stolnikow has pointed out, the liver acts to a considerable extent as a blood reservoir on the systemic circulation, so that the right heart may take a greater or less volume of blood from the great veins without materially modifying the systemic pressure. So the lungs play a similar part to the left heart, acting as a reservoir in which blood may be stored if the left heart for some reason diminishes its output, and conversely contains a reserve of blood upon which the left heart draws when its output increases. It is this very close relationship to the two sides of the heart which makes the study of the pulmonary circulation of such difficulty and has led many workers into considerable errors.

In these lectures we shall therefore discuss the various experiments which we have performed in the following order: (1) the alterations in the pulmonary circulation due to purely cardiac changes; (2) the alterations due to variations in the systemic circulation, which may effect changes by alterations in the output of the left heart or by modification in the flow to the right heart; and (3) an examination of any changes due to alterations in the resistance offered by the pulmonary vessels.

The blood volume curve given by a lobe of the lung in which the bronchus has been plugged in the manner described above gives the following features. There is a small increase in volume at each inflation by the artificial respiration apparatus of the remaining lobes of the two lungs, and there is a very marked volume pulse occurring with each heart beat. This volume-pulse is systolic in time and is therefore due to the output from the right heart.

Turning in the first instance to the effect of alterations in cardiac activity upon the pulmonary circulation we may first of all discuss the changes caused by excitation of the augmentors and accelerators on the one hand and of the inhibitory fibres on the other. Stimulation of the accelerator fibres which also usually causes augmentation, as a rule, leads to an increase in the volume of the lung and a rise in the aortic pressure. The increased volume of the lung usually persists longer than the rise in aortic pressure. In a few instances no increase in lung-volume is recorded and these cases are usually accompanied by a more marked rise in aortic pressure. Simultaneous records of the blood-pressure in the pulmonary artery and aorta show a marked rise in the former which may or may not be accompanied by a rise in aortic pressure. From these results we conclude that the nerves chiefly affect the right side. The output from this side usually shows a greater increase than that from the left; hence the blood volume of the lung is increased. The various effects upon the aortic pressure show how variable the action is upon the left heart.

Stimulation of the vagus also gives very interesting results. With weak stimulation, resulting in much slower beat, the aortic pressure falls gradually and a marked decrease in the volume of the lung is recorded. A stronger stimulation, resulting in a much more marked fall in aortic pressure, leads to a quicker decrease in the lung-volume which, however, is no more extensive. In these cases the right auricle pressure rises considerably, but the effect upon the left auricle is much less marked. Hence we must conclude that the action of the vagus upon the heart is more particularly felt upon the right side. The diminution in volume of the lung can only mean a larger diminution in output of the right ventricle as compared to that of the left.

The next series of changes to be studied are those due primarily to an alteration in the systemic circulation. Of these we must distinguish two groups—namely, those in which respectively a rise or a fall in the aortic pressure is produced. These may exert an effect upon the pulmonary circulation either through a change in the rate of flow of blood into the right auricle, or by affecting the output from the left heart. At present the latter of these two factors has been chiefly studied.

As the simplest case we may take the effect of restricting the outflow from the aorta by partially or completely blocking the aorta at the lower end of the thorax. Waller and later observers have shown that the result of clamping the aorta is to cause a big rise in the aortic pressure, followed quickly by one in the left auricle. There is no rise in the pulmonary artery pressure unless the compression is kept up longer than about 15 seconds. There is usually no effect upon the right auricle pressure. We have found that the effect upon the lung as observed by recording its volume changes is to produce a very marked congestion, the mode of production of which is in the failure of the left ventricle to empty itself against the raised aortic pressure. In consequence of this fall in output from the left side the blood in the pulmonary veins cannot flow in normal quantities into the left auricle and is therefore accumulated in the pulmonary veins and capillaries. There is no incompetence of the mitral valves. A quite analogous series of changes is also observed when other procedures for raising the systemic pressure, apart from a direct action upon the heart, have been adopted, such as stimulation of the medulla, the vagi having been previously divided, stimulation of the divided splanchnics, or stimulation of the upper surface of the spinal cord which has been divided in the lower cervical region.

We next come to the effects produced by methods which act upon the heart as well as the blood-vessels. Of these one of the most important is suprarenal extract. This is known to cause a large rise in aortic pressure due chiefly to constriction of the peripheral arterioles; but it also acts upon the heart, whose rate is increased and output nearly doubled. The effect on the heart, however, is complicated, if the vagi be undivided, by a marked inhibition of the heart occurring mainly during the period of heightened aortic pressure. The effect of suprarenal extract upon the blood-volume of the lung is to cause first a small diminution in volume, soon followed by a marked increase which persists during, and for a short time after, the rise in aortic pressure. Thus the main effect is to produce a distinct congestion of the lungs. The effect upon the pulmonary blood-pressure is a rise to nearly double its original valve, commencing with, but lasting rather longer than, the rise in aortic pressure. The left auricle pressure at first falls, but rises rapidly when the aortic pressure has reached a high point. The effect upon the right auricle pressure is a gradual and slight rise following the rise in aortic pressure. From these results we may conclude that the effects are mainly due to the action of the peripheral blood-vessels in causing the large rise in aortic pressure. They are, however, complicated by the action upon the heart. The increased output observed at first explains the preliminary diminution in volume of the lung and the rise in pulmonary pressure. The later effects are due to the rise in the aortic pressure and the consequent inability of the left ventricle to empty itself. The more reflex inhibition there is produced, the more marked, as a rule, is the pulmonary congestion. These facts have an important bearing upon the question whether suprarenal extract can be advantageously used in hæmorrhage from the lungs Certainly in the doses which we have employed, and with intravenous injection, our experiments strongly contraindicate its employment for such a purpose. Whether a smaller dose, given by the mouth, so that the admittance into the circulation is much more gradual, can produce a pulmonary constriction unaccompanied by a congestion is now being investigated. Some further points in regard to the action of the extract upon the pulmonary vessels are described below

A drug of importance to us, in that it causes a fall in the systemic pressure, is amyl nitrite. This is known to produce its main effect by dilatation of the peripheral blood-vessels. The disadvantage against us here is that we are not quite certain of the details of its action upon the heart. In the cat a small dose of amyl nitrite sufficient to cause a marked fall in aortic pressure causes a large congestion of the lung, which takes place in two stages. There is a primary and moderate increase in the blood-volume, followed by a slight diminution, and this again is succeeded by the main volume increase, the nature of the record seeming to show that we are dealing with at least two different effects. The blood-pressure changes, so far as we have at present decided, have shown only slight changes, the main one being a rise in the left auricle pressure. The effect upon the pulmonary pressure is very slight and mainly in the direction of a late rise. We think, therefore, that the probable explanation of the congestion produced in the lung is a preliminary dilatation due to the increased flow to the right side of the heart, followed by a later effect due to the action upon the heart which is mainly expressed upon the left side. This fails to empty itself so completely and thus accounts for the rise in the pressure in the left auricle. In the dog the effect is not quite so striking. The changes are in the same direction but are much less in degree. There is probably a much better compensation in this animal than in the cat.

### ARE THERE VASO-CONSTRICTOR NERVES TO THE PULMONARY ARTERIES?

This question has been already worked at by many observers; but we need here only consider the facts brought forward by Bradford and Dean and by François-Franck. All these observers came to the conclusion that there are vaso-constrictor nerves. The evidence looked for by Bradford and Dean was in one of three directions. First, a rise in the pulmonary pressure out of proportion to the aortic pressure; secondly, a rise in the pulmonary pressure with no accompanying rise in the aortic pressure; or, thirdly, a rise in pulmonary pressure accompanied by a fall in aortic pressure. In one series of their experiments they excited the vaso-motor centre in the medulla, having previously divided both vagi. This caused a large rise in the aortic pressure and a fairly well-marked rise in the pulmonary pressure. The spinal cord was then divided between the sixth and seventh dorsal nerves and the stimulation repeated. The aortic-pressure rise was now less than before, but there was the same rise in the pulmonary pressure. Direct evidence was also sought by stimulation of the anterior roots of the upper dorsal nerves. This caused a rise varying in amount, but never very marked, in the pulmonary pressure, accompanied at times by a fall in the aortic pressure, at other times by a rise varying with different animals and with the nerve stimulated. From experiments such as these they concluded that the only explanation of the pulmonary rise is an active constriction of the pulmonary arterioles.

François-Franck's main method was to simultaneously measure the blood-pressure in the pulmonary artery and in the left auricle, and he considers that a rise in the former, accompanied by a fall in the latter, must mean pulmonary constriction. In his experiments he stimulated the sympathetic chain in the thorax from the sixth thoracic nerve up to the ganglion stellatum. The usual results he obtained were a rise in the pulmonary pressure, a fall in the pressure of the left auricle, and, as a rule, a fall in the aortic pressure On some occasions he observed a rise in the aortic pressure In some of his experiments he recorded the blood-volume of the lung by a plethysmographic method, and invariably obtained an increase in volume as the result of the excitation of these nerves. This is an effect the reverse to that which we should *a priori* expect, and he supposes the result to be due to the great distensibility of the pulmonary arteries. If the arterioles are constricted over the whole lung the blood would be stored in the large vessels, and he supposes that the increase in volume thus caused is more than sufficient to compensate for the diminished volume in the capillaries and veins.

Our criticism of the results of all these experiments lies in two directions. First, the effects obtained are always very small, and all observers agree that the influence of the nerves on the blood-vessels can only be of slight degree. But the main objection to these experiments is that they have not sufficiently excluded the action of the nerves upon the heart; and until this is done it is impossible to rely on experiments of this class. Bradford and Dean consider that by taking into account those tracings only in which no apparent cardiac acceleration is to be seen any changes must be due to an action upon the pulmonary blood-vessels Roy and Adami, however, have shown that excitation of some of the sympathetic fibres running to the heart gives rise to augmentation without acceleration, and many of our experiments have quite clearly corroborated this. If augmentation takes place without acceleration the pulmonary pressure will rise because the output from the right side is increased. The aortic pressure will also tend to rise because the output from the left side is increased; the pressure in the left auricle will fall because the left ventricle is taking more per beat; and these are the effects which we think have in reality taken place in the records of these observers. The only difficulty lies in explaining the fall in aortic pressure which they have commonly obtained. Bradford and Dean experienced exactly the same difficulty and concluded that their experiments were not sufficient to decide the cause of this fall. That augmentation has taken place in many of François-Franck's experiments is quite clear from his own tracings, for where he includes the volume-curve of the lung there is always a quite marked increase in the volume-pulse which can only indicate an increased output from the right heart.

Turning next to our own experiments we have stimulated the white rami communicantes of the upper thoracic nerves, the sympathetic chain itself, and the fibres from the ganglion stellatum. We have also attempted to exclude any possible cardiac action by a preliminary division of all the branches of the sympathetic that we could find running into the heart. We have, however, found that it is quite impossible to divide all these fibres without injuring those running to the root of the lung. We have also stimulated the fibres at the root of the lung, but in this position we have only obtained completely negative results. The usual effect of stimulating the fibres leaving the ganglion stellatum is a fall in the volume of the lung, quickly followed by an increase. In some cases we recorded an increase in the volume of the lung from the start, and in a few cases, which, however, are very rare, we have observed a diminution in the volume of the lung during the whole time of stimulation. Wherever we got a diminution in the volume of the lung we invariably found an increased volume pulse, and simultaneously a rise in the aortic pressure. We think that the whole effect is best explained by the cardiac augmentation which these results indicate, and that it is not necessary to invoke any action upon the pulmonary vessels for their explanation. In those cases in which there is an increase in volume of the lung from the start there is usually an increased volume pulse and the aortic pressure shows in many cases practically no change, and lastly in those cases, the commonest, in which a preliminary diminution is followed by an increase in the volume of the lung the increase in volume pulse is well marked, especially at first, and there is a decided rise in aortic pressure, followed by a gradual fall as the volume of the lung increases. Stimulation of the accelerator nerve itself, after it has left the ganglion stellatum, produces as a rule an increased volume of the lung, with increased volume pulse. Hence we conclude that all the results that we have obtained can also be explained in the simplest manner as of purely cardiac origin, and we therefore attempted to detect vaso-constrictor nerves, if any are present, by a different type of experiment. The nerves to be stimulated having been isolated the animal was killed by bleeding; the blood was whipped and was placed in a reservoir. Meanwhile cannulæ were tied in the pulmonary artery and in the left auricle. One lung was then ligatured at the root. The cannula in the artery was then connected to the reservoir and blood perfused at constant pressure through the intact lung. The outflow was then recorded by a graphic method. We never obtained the least effect on stimulating any of the fibres leaving the ganglion stellatum, and hence we conclude that there are no vaso-constrictor fibres to the pulmonary vessels. Experiments of this type, we think, would certainly have given us a positive result had such fibres been present, for it is easy to obtain such results with, for instance, the nerves to the vessels of a limb

### THE ACTION OF SOME DRUGS UPON THE PULMONARY CIRCULATION.

We have already stated the general effects of suprarenal extract upon the lung and pulmonary circulation. We have also investigated the action of the suprarenal on the pulmonary arteries by direct perfusion. It gives us a very striking result; whereas perfusion of very dilute suprarenal extract through any of the systemic vessels causes their almost complete closure, the effect upon the pulmonary vessels is in nearly all cases exactly the opposite—namely, a markedly increased rate of flow. Only in one instance have we obtained constriction, and then the effect, though marked, was in no degree comparable to that which we should obtain, for instance, upon a limb. These experiments are, of course, of importance in considering whether suprarenal extract is of value in hæmorrhage from the lungs, but our conclusions up to the present must be somewhat guarded because our experiments have not yet sufficiently decided the action of small doses. With regard to the volume changes produced in the lung by suprarenal extract the dog again shows a difference from the cat. The changes, though in the same direction, are very much smaller and the dilatation is more accentuated if the vagi have been previously subdivided—a result which we should naturally expect from the much greater and more prolonged rise of aortic pressure that occurs under these circumstances.

The action of nicotine is somewhat similar to that of suprarenal extract, though, as it exerts less effect upon the heart, its action being mainly confined to the peripheral blood-vessels, the results are rather simpler. Still, they are in the same direction—that is, to the rise in the aortic pressure there follows a congestion of the lung and simultaneously a rise in the pulmonary vein pressure and pulmonary artery pressure.

Pilocarpine gives interesting results in that it tends to produce systemic vaso-constriction, the effect of which is, however, obscured by the marked cardiac inhibition simultaneously produced. If the cardiac inhibitory fibres be paralysed by atropine, pilocarpine produces practically the same results as nicotine. When given with the cardio-inhibitory mechanism intact it produces a great increase in the volume of the lung which is due to the cardiac inhibition. As this decrease in volume takes place it must mean that the output from the left heart is less diminished than is that from the right heart. Muscarine produces the same effects as pilocarpine.

# THE EDUCATION OF EPILEPTICS.

BY WILLIAM ALEXANDER, M.D. R.U.I., F.R.C.S. ENG.,
HONORARY SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL, ACTING CONSULTING SURGEON TO THE HOME FOR EPILEPTICS, MAGHULL.

TWELVE years ago the first step in improving the position and comfort of epileptics in England was taken at Liverpool by the establishing of the epileptic homes at Maghull. Previously to that time our epileptics, if they were poor, were consigned to the imbecile wards of the workhouse, and if they were rich they were looked after by relatives or by attendants, or were taken as boarders by people of various classes of life, who for a consideration relieved the parents of trouble and responsibility without being always qualified for the duties which they thus undertook. The condition of those epileptics whose relatives were unable to engage caretakers and who did not wish to send them to the workhouse was often miserable in the extreme. The relatives were always kept in a state of constant anxiety and dread, and the patients were frequently so confined to limited surroundings and denied all liberty that it was no wonder that they became imbecile, stupid, or even insane. In spite of all the precautions of anxious relatives and attendants dangerous and sometimes fatal accidents frequently occurred, and the death of the unfortunate patient was too often considered a special providence and relief to all concerned. In the workhouses the patients were simply "herded" with the imbeciles and the harmless insane inmates, without any effort being made for instruction, employment, or amusements. The primary objects of the establishment of the colony at Maghull were to keep epileptic patients safe, to occupy and to train their bodies and minds, and to give them as much liberty as possible with due regard to their safety and to the feelings and prejudices of their neighbours. These objects have been successfully carried out and to an unexpected extent. But it was found as the work of mental and physical training progressed that the education of the patients was often in a very backward state and required to be dealt with.

Defective education arose from various causes. In a considerable number of cases the patients were kept from school by order of their medical attendants, under the plea that the brain must not be excited or that the patient must not be "bothered." The patient was allowed to do whatever was most agreeable—and education that necessitates "going to school" is not generally agreeable to a large majority of young children. The relatives, following up the professional advice to its logical conclusion, allowed the patients to do as they liked in all other matters as well as in regard to education, and the little rascals soon found out that they could compel the relatives to give them whatsoever they wanted by simulating the symptoms of the onset of an attack. This course of treatment of young epileptics cannot be too the outflow from the aorta by partially or completely blocking the aorta at the lower end of the thorax. Waller and later observers have shown that the result of clamping the aorta is to cause a big rise in the aortic pressure, followed quickly by one in the left auricle. There is no rise in the pulmonary artery pressure unless the compression is kept up longer than about 15 seconds. There is usually no effect upon the right auricle pressure. We have found that the effect upon the lung as observed by recording its volume changes is to produce a very marked congestion, the mode of production of which is in the failure of the left ventricle to empty itself against the raised aortic pressure. In consequence of this fall in output from the left side the blood in the pulmonary veins cannot flow in normal quantities into the left auricle and is therefore accumulated in the pulmonary veins and capillaries. There is no incompetence of the mitral valves. A quite analogous series of changes is also observed when other procedures for raising the systemic pressure, apart from a direct action upon the heart, have been adopted, such as stimulation of the medulla, the vagi having been previously divided, stimulation of the divided splanchnics, or stimulation of the upper surface of the spinal cord which has been divided in the lower cervical region.

We next come to the effects produced by methods which act upon the heart as well as the blood-vessels. Of these one of the most important is suprarenal extract. This is known to cause a large rise in aortic pressure due chiefly to constriction of the peripheral arterioles; but it also acts upon the heart, whose rate is increased and output nearly doubled. The effect on the heart, however, is complicated, if the vagi be undivided, by a marked inhibition of the heart occurring mainly during the period of heightened aortic pressure. The effect of suprarenal extract upon the blood-volume of the lung is to cause first a small diminution in volume, soon followed by a marked increase which persists during, and for a short time after, the rise in aortic pressure. Thus the main effect is to produce a distinct congestion of the lungs. The effect upon the pulmonary blood-pressure is a rise to nearly double its original valve, commencing with, but lasting rather longer than, the rise in aortic pressure. The left auricle pressure at first falls, but rises rapidly when the aortic pressure has reached a high point. The effect upon the right auricle pressure is a gradual and slight rise following the rise in aortic pressure. From these results we may conclude that the effects are mainly due to the action of the peripheral blood-vessels in causing the large rise in aortic pressure. They are, however, complicated by the action upon the heart. The increased output observed at first explains the preliminary diminution in volume of the lung and the rise in pulmonary pressure. The later effects are due to the rise in the aortic pressure and the consequent inability of the left ventricle to empty itself. The more reflex inhibition there is produced, the more marked, as a rule, is the pulmonary congestion. These facts have an important bearing upon the question whether suprarenal extract can be advantageously used in hæmorrhage from the lungs Certainly in the doses which we have employed, and with intravenous injection, our experiments strongly contraindicate its employment for such a purpose Whether a smaller dose, given by the mouth, so that the admittance into the circulation is much more gradual, can produce a pulmonary constriction unaccompanied by a congestion is now being investigated. Some further points in regard to the action of the extract upon the pulmonary vessels are described below

A drug of importance to us, in that it causes a fall in the systemic pressure, is amyl nitrite. This is known to produce its main effect by dilatation of the peripheral blood-vessels The disadvantage against us here is that we are not quite certain of the details of its action upon the heart In the cat a small dose of amyl nitrite sufficient to cause a marked fall in aortic pressure causes a large congestion of the lung, which takes place in two stages. There is a primary and moderate increase in the blood-volume, followed by a slight diminution, and this again is succeeded by the main volume increase, the nature of the record seeming to show that we are dealing with at least two different effects. The blood-pressure changes, so far as we have at present decided, have shown only slight changes, the main one being a rise in the left auricle pressure. The effect upon the pulmonary pressure is very slight and mainly in the direction of a late rise. We think, therefore, that the probable explanation of the congestion produced in the lung is a preliminary dilatation due to the increased flow to the right side of the heart, followed by a later effect due to the action upon the heart which is mainly expressed upon the left side. This fails to empty itself so completely and thus accounts for the rise in the pressure in the left auricle. In the dog the effect is not quite so striking. The changes are in the same direction but are much less in degree. There is probably a much better compensation in this animal than in the cat.

### ARE THERE VASO-CONSTRICTOR NERVES TO THE PULMONARY ARTERIES?

This question has been already worked at by many observers; but we need here only consider the facts brought forward by Bradford and Dean and by François-Franck. All these observers came to the conclusion that there are vaso-constrictor nerves. The evidence looked for by Bradford and Dean was in one of three directions. First, a rise in the pulmonary pressure out of proportion to the aortic pressure; secondly, a rise in the pulmonary pressure with no accompanying rise in the aortic pressure; or, thirdly, a rise in pulmonary pressure accompanied by a fall in aortic pressure. In one series of their experiments they excited the vaso-motor centre in the medulla, having previously divided both vagi. This caused a large rise in the aortic pressure and a fairly well-marked rise in the pulmonary pressure. The spinal cord was then divided between the sixth and seventh dorsal nerves and the stimulation repeated. The aortic-pressure rise was now less than before, but there was the same rise in the pulmonary pressure. Direct evidence was also sought by stimulation of the anterior roots of the upper dorsal nerves. This caused a rise varying in amount, but never very marked, in the pulmonary pressure, accompanied at times by a fall in the aortic pressure, at other times by a rise varying with different animals and with the nerve stimulated. From experiments such as these they concluded that the only explanation of the pulmonary rise is an active constriction of the pulmonary arterioles.

François-Franck's main method was to simultaneously measure the blood-pressure in the pulmonary artery and in the left auricle, and he considers that a rise in the former, accompanied by a fall in the latter, must mean pulmonary constriction. In his experiments he stimulated the sympathetic chain in the thorax from the sixth thoracic nerve up to the ganglion stellatum. The usual results he obtained were a rise in the pulmonary pressure, a fall in the pressure of the left auricle, and, as a rule, a fall in the aortic pressure On some occasions he observed a rise in the aortic pressure In some of his experiments he recorded the blood-volume of the lung by a plethysmographic method, and invariably obtained an increase in volume as the result of the excitation of these nerves. This is an effect the reverse to that which we should *a priori* expect, and he supposes the result to be due to the great distensibility of the pulmonary arteries If the arterioles are constricted over the whole lung the blood would be stored in the large vessels, and he supposes that the increase in volume thus caused is more than sufficient to compensate for the diminished volume in the capillaries and veins.

Our criticism of the results of all these experiments lies in two directions. First, the effects obtained are always very small, and all observers agree that the influence of the nerves on the blood-vessels can only be of slight degree But the main objection to these experiments is that they have not sufficiently excluded the action of the nerves upon the heart; and until this is done it is impossible to rely on experiments of this class. Bradford and Dean consider that by taking into account those tracings only in which no apparent cardiac acceleration is to be seen any changes must be due to an action upon the pulmonary blood-vessels Roy and Adami, however, have shown that excitation of some of the sympathetic fibres running to the heart gives rise to augmentation without acceleration, and many of our experiments have quite clearly corroborated this. If augmentation takes place without acceleration the pulmonary pressure will rise because the output from the right side is increased. The aortic pressure will also tend to rise because the output from the left side is increased; the pressure in the left auricle will fall because the left ventricle is taking more per beat; and these are the effects which we think have in reality taken place in the records of these observers. The only difficulty lies in explaining the fall in aortic pressure which they have commonly obtained. Bradford and Dean experienced exactly the same difficulty and concluded that their experiments were not sufficient to decide the cause of this fall That augmentation has taken place in many of François Franck's experiments is quite clear from his own tracings, for where he includes the volume curve of the lung there is always a quite marked increase in the volume pulse which can only indicate an increased output from the right heart

Turning next to our own experiments we have stimulated the white rami communicantes of the upper thoracic nerves the sympathetic chain itself, and the fibres from the ganglion stellatum We have also attempted to exclude any possible cardiac action by a preliminary division of all the branches of the sympathetic that we could find running into the heart We have, however, found that it is quite impossible to divide all these fibres without injuring those running to the root of the lung We have also stimulated the fibres at the root of the lung but in this position we have only obtained completely negative results The usual effect of stimulating the fibres leaving the ganglion stellatum is a fall in the volume of the lung, quickly followed by an increase In some cases we recorded an increase in the volume of the lung from the start, and in a few cases, which, however, are very rare, we have observed a diminution in the volume of the lung during the whole time of stimulation Wherever we got a diminution in the volume of the lung we invariably found an increased volume pulse, and simultaneously a rise in the aortic pressure We think that the whole effect is best explained by the cardiac augmentation which these results indicate, and that it is not necessary to invoke any action upon the pulmonary vessels for their explanation In those cases in which there is an increase in volume of the lung from the start there is usually an increased volume pulse and the aortic pressure shows in many cases practically no change, and lastly in those cases the commonest, in which a preliminary diminution is followed by an increase in the volume of the lung especially the increase in volume pulse is well marked, especially at first, and there is a decided rise in aortic pressure, followed by a gradual fall as the volume of the lung increases Stimulation of the accelerator nerve itself, after it has left the ganglion stellatum, produces as a rule an increased volume of the lung, with increased volume pulse Hence we conclude that all the results that we have obtained can also be explained in the simplest manner as of purely cardiac origin and we therefore attempted to detect vaso constrictor nerves if any are present, by a different type of experiment The nerves to be stimulated having been isolated the animal was killed by bleeding, the blood was whipped and was placed in a reservoir Meanwhile cannulæ were tied in the pulmonary artery and in the left auricle One lung was then ligatured at the root The cannula in the artery was then connected to the reservoir and blood perfused at constant pressure through the intact lung The outflow was then recorded by a graphic method We never obtained the least effect on stimulating any of the fibres leaving the ganglion stellatum and hence we conclude that there are no vaso constrictor fibres to the pulmonary vessels Experiments of this type, we think, would certainly have given us a positive result had such fibres been present for it is easy to obtain such results with, for instance the nerves to the vessels of a limb

### The Action of some Drugs upon the Pulmonary Circulation

We have already stated the general effects of suprarenal extract upon the lung and pulmonary circulation We have also investigated the action of the suprarenal on the pulmonary arteries by direct perfusion It gives us a very striking result, whereas perfusion of very dilute suprarenal extract through any of the systemic vessels causes their almost complete closure the effect upon the pulmonary vessels is in nearly all cases exactly the opposite—namely a markedly increased rate of flow Only in one instance have we obtained constriction and then the effect, though marked was in no degree comparable to that which we should obtain for instance upon a limb These experiments are of course of importance in considering whether suprarenal extract is of value in hæmorrhage from the lungs but our conclusions up to the present must be somewhat guarded because our experiments have not yet sufficiently decided the action of small doses With regard to the volume changes produced in the lung by suprarenal extract the dog again shows a difference from the cat The changes, though in the same direction are very much smaller and the dilatation is more accentuated if the vagi have been previously subdivided—a result which we should naturally expect from the much greater and more prolonged rise of aortic pressure that occurs under these circumstances

The action of nicotine is somewhat similar to that of suprarenal extract, though, as it exerts less effect upon the heart, its action being mainly confined to the peripheral blood vessels, the results are rather simpler Still, they are in the same direction—that is, to the rise in the aortic pressure there follows a congestion of the lung and simultaneously a rise in the pulmonary vein pressure and pulmonary artery pressure

Pilocarpine gives interesting results in that it tends to produce systemic vaso constriction, the effect of which is, however obscured by the marked cardiac inhibition simultaneously produced If the cardiac inhibitory fibres be paralysed by atropine pilocarpine produces practically the same results as nicotine When given with the cardio inhibitory mechanism intact it produces a great increase in the volume of the lung which is due to the cardiac inhibition As this decrease in volume takes place it must mean that the output from the left heart is less diminished than is that from the right heart Muscarine produces the same effects as pilocarpine

# THE EDUCATION OF EPILEPTICS

By WILLIAM ALEXANDER, M D R U I, F R C S Eng.,
HONORARY SURGEON TO THE ROYAL SOUTHERN HOSPITAL LIVERPOOL ACTING CONSULTING SURGEON TO THE HOME FOR EPILEPTICS MAGHULL

TWELVE years ago the first step in improving the position and comfort of epileptics in England was taken at Liverpool by the establishing of the epileptic homes at Maghull Previously to that time our epileptics if they were poor, were consigned to the imbecile wards of the workhouse, and if they were rich they were looked after by relatives or by attendants or were taken as boarders by people of various classes of life who for a consideration relieved the parents of trouble and responsibility without being always qualified for the duties which they thus undertook The condition of those epileptics whose relatives were unable to engage caretakers and who did not wish to send them to the workhouse was often miserable in the extreme The relatives were always kept in a state of constant anxiety and dread, and the patients were frequently so confined to limited surroundings and denied all liberty that it was no wonder that they became imbecile stupid or even insane In spite of all the precautions of anxious relatives and attendants dangerous and sometimes fatal accidents frequently occurred, and the death of the unfortunate patient was too often considered a special providence and relief to all concerned In the workhouses the patients were simply "herded" with the imbeciles and the harmless insane inmates without any effort being made for instruction employment, or amusements The primary objects of the establishment of the colony at Maghull were to keep epileptic patients safe to occupy and to train their bodies and minds and to give them as much liberty as possible with due regard to their safety and to the feelings and prejudices of their neighbours These objects have been successfully carried out and to an unexpected extent But it was found as the work of mental and physical training progressed that the education of the patients was often in a very backward state and required to be dealt with

Defective education arose from various causes In a considerable number of cases the patients were kept from school by order of their medical attendants under the plea that the brain must not be excited or that the patient must not be "bothered" The patient was allowed to do whatever was most agreeable and education that necessitates going to school is not generally agreeable to a large majority of young children The relatives following up the professional advice to its logical conclusion allowed the patients to do as they liked in all other matters as well as in regard to education and the little rascals soon found out that they could compel the relatives to give them whatsoever they wanted by simulating the symptoms of the onset of an attack This course of treatment of young epileptics cannot be too strongly or too publicly condemned. The growing brain that has been disturbed by a fit can only be strengthened and improved by judicious education, especially by teaching habits of self-control and of self-denial such as have to be taught to all other children. It cannot be wondered at that the very opposite treatment produces little savages that have developed habits very difficult to eradicate, and that any information which they possess is very often useless or of an undesirable kind. The most frequent cause of deficient education was, however, found to be the direct effect of the epileptic attacks We have had several examples of patients who before epilepsy developed were bright, intelligent, and even precocious children, and who promised to become good scholars and to be a credit to their parents and their teachers. Sometimes after the first attack, or sometimes after a series of attacks at the onset of the disease, the brains of these children have been, as it were, swept clean like that of a baby, and the patients have become suddenly dispossessed of all the knowledge they had acquired. In many of these cases, however, only certain of the mental faculties are impaired. The faculty of computation suffers very frequently (in some notable exceptions this faculty curiously has remained strongly developed amidst a very general wreck), and memory also suffers severely.

Re-education is a slow, difficult, and irksome process under such cerebral conditions and requires to be intelligently carried on and in directions suitable to each case Sometimes re-education has to be entirely of a mechanical kind as the patient does not appear to have any powers of continuous thinking but is well able to direct his physical energies. Others learn with avidity and soon regain what has been lost In other cases certain faculties are highly developed; the musical, the imitative, and introspective faculties are instances of this. In the latter most minute self-analyses are constantly being made and these do not conduce to the patient's happiness and welfare. Other children will labour diligently to re-learn to write, to read, and to cipher, but the task is a very uphill one on account of the great defectiveness of their memory. The lessons of the day, that seem at the time to be thoroughly studied and acquired, are to a large extent forgotten by the next afternoon, and teachers are prone to give way to despair until they find out that the normal rate of progress is necessarily slow; but still there *is* progress and that progress increases as the experience of the teacher in teaching epileptics increases. The education of epileptics can best be carried on after close consultation between the medical officer and the teachers, so that the latter may be prevented from wasting strength and enthusiasm in trying to educate a faculty of the brain that has been entirely lost and may devote their energies to the education of those powers which still remain, and so to educate them that they may be of practical use to the patient in after years. The education of our patients resolves itself into two classes—first, of all those who are of the ordinary school age, and secondly of older patients whose education has been defective, or in whom the results of early education have been lost through the disease from which they suffer.

The great majority of the patients at Maghull have had opportunities of being educated and have been to school up to puberty. An analysis of the notes of 385 patients shows that 162 did not leave school till the age of 15 years, that 63 did not leave school till they were 12 years of age, and that 58 did not leave school till they were 10 years old; 18 have been educated at home, while 37 have either not been at school at all or were so irregular that they had no education whatever. Of 39 we have no information as to how they have been educated. The state of the education of these patients when they were admitted to the home was in 45 cases *nil*, in 87 imperfect, in 119 fair, and in 134 good. In these 385 cases we find that in 47 cases epilepsy began soon after birth, in 38 cases before five years of age, in 87 cases before 10 years of age, in 25 cases before 12 years of age, in 39 cases before 14 years of age, and in 122 cases after 14 years of age, so that in 186 cases epilepsy did not set in till the children were over 10 years of age.

The children of school age whom we have at Maghull are under the care of a teacher who trains them as far as possible according to the capacities of their minds and with whom they spend a certain number of hours daily either at work or at play. The adults whose education has been defective or has been impaired by the disease go to an evening continuation school managed by teachers according to the requirements of the Board of Education. This continuation school has been very satisfactory in every way. It interests the patients, it improves their education, and it occupies in a useful way a certain number of evenings during the winter season. The school inspectors approved of it very highly and we have been able to obtain a small grant from the Education Department. The subjects taught are reading, writing, arithmetic, wood-carving, joinery, and different technical subjects.

The day-school for the children has been equally beneficial from every point of view, except that of the Education Department. When we applied to that Department for a grant to our day-school we found that we had to comply with certain regulations which seemed to us very unnecessary and even undesirable. Our establishment has *grown* up, the buildings being added according to what we, from experience, decided would best supply our wants. The Department has, however, laid down certain arbitrary rules for the education of epileptic children, conspicuous amongst them being the following—viz, that the children must live entirely on the ground floor, and not have to ascend stairs of any kind; that not more than 15 are to live in one cottage; and that there are not to be more than four cottages in any one establishment. The children must also be completely isolated from adults during the whole course of their school life. Now, we could not fulfil these conditions without recasting our colony, incurring great expense, and giving up principles of management too precious in our opinion to be abandoned without sufficient practical reasons for the change. At the time that we made this application the only other home in England was that at Chalfont, and on applying to the authorities there we found that although they had built cottages much smaller than any of our buildings and could have managed to comply with the "ground-floor law" they could not fulfil the requirements of the Education Department, and we believe that they have consequently arranged not to undertake the task of educating epileptic children under the Department. We persevered, however, with our application and the Department sent down an inspector. The final decision was that the Department would not assist us by any grant in educating the few children whom we had at our home at Maghull unless we would spend a large amount of money that we could ill afford to use for this purpose.

Now, the question that has sorely puzzled us is where the experience that dicated the regulations for the treatment of epileptic children was obtained. Our home at Maghull was the first establishment of its kind in Great Britain, and that at Chalfont the second, and although there are others being constructed none of them have yet come before the public as working institutions. The Maghull Home has been in existence for 12 years and now contains about 140 patients of all ages and sizes who have been going up and down stairs all these years, and we have not found that the stairs are so dangerous as to require their abolition Indeed, as far as our experience actually goes, the patients seem to be safer on the stairs than they are on the ground floor. Of course, this seems a ridiculous statement, but it has reason on its side, as patients when exercising their faculties do not as a rule have attacks. It proves that this idea of no stairs, as far as danger to epileptics is concerned, is an old woman's fancy. It is a view that appeals to the ladies and we have had often great difficulty in freeing strong and vigorous epileptics from the thraldom of affectionate relatives who are only content when their epileptic, the object of their care, is on a bed or a sofa with somebody sitting alongside. We have occasionally seen epileptic patients going down the stairs in their own houses. A nervous mother or other relative stands at the foot of the stairs calling out from below in a tone of anguish, "Be careful," or "Take care"; two other relatives hold the patient at either side, all in a state of dread and excitement that certainly should be sufficient to induce a fit if anything could possibly induce one; and probably a fourth walks behind calling out directions from above. The patients are, of course, very indignant—and, I think, justly indignant—at being treated as such helpless objects, and would it be any wonder if after years of such precautions such patients would actually at the last find themselves unable to go up or down stairs at all? Where did the Department of Education learn this experience of the dangers of stairs? Certainly not in Germany, for we have been through a good number of the institutions in that country, and we have not found any epileptic institutions where they have not stairs. In fact, the stairs seem to be more in evidence there than in any home in this country. We do not advise *steep* stairs. We have made safe stairs, and we take care that certain patients go down stairs in the morning and stay down as far as possible till the evening, and that they are watched by nurses during the time that they are going up or down stairs, and we do not think that anything more is necessary in regard to stairs. An epileptic may easily lose his life even in a padded room unless he is looked after, and when well looked after epileptics are safe under all usual conditions of life. We believe in *supervision*, and not in *architecture*, for our patients' safety, and our experience has fully justified our faith.

The Education Department does not propose that these children shall be kept in stairless houses all their days. They will grow up to adult life. They will go home or they will go to other institutions, and it is not practical to insist that people who have epileptics in their family must keep them down stairs all the time, or that institutions or people who have anything to do with adult epileptics should have rooms for them on the ground floor, and yet such would be the logical inference to be drawn from such regulations If not, it is certain that if children are not allowed to go up and down stairs during their school life they will be very much less fitted for going up and down stairs safely if they only begin the ascent and descent when their habits have been acquired. I think that we may therefore call upon the Education Department to show some valid reasons for this regulation or to delete it from the conditions of epileptic schools. Besides, at the present stage, when the practical education of epileptics is really confined to one or two institutions, it seems a mistake not to encourage efforts to correct this defect of the educational system until the Government or a local authority has established schools.

We now come to the second regulation—of not having more than 15 children in a cottage, and of their being entirely separate from adults. Of course, the idea of the Education Department is to imitate family life. Well, 15 is a large family, and the idea of calling this "family life" pleases philanthropists who have a crank that way more than it really imitates in any sense of the term what we understand by family life Family life means father and mother, big brothers and sisters, and small brothers and sisters, and servants and attendants of various kinds. The big ones look after the little ones and they do each other good in their offices towards each other. In family life they go to schools, they mix in the playground with all sorts of boys and girls, at home they come in contact with relatives and friends, and in the streets and lanes they meet with strangers old and young In these Government epileptic schools, limited by sex and by age, and with strangers looking after such a large number, where does the family life come in? The children in these schools will be useless and helpless noodles unless after leaving such a school they are "licked" into human shape by the influences that mould the best humanity. We maintain that we have the best family life at Maghull. The boys and the girls live in separate buildings, where they sleep, of course, in separate rooms from the adults. From each building they go to school—a mixed school. Here they are under the teacher for the day, but in the evenings they take part in social life, and share in entertainments with the bigger boys and girls, due precautions being taken through the constant supervision of nurses that the companions are suitable and that the bigger patients who would take up with a younger child are suitable for that companionship. We know that special care has to be taken with epileptics in these matters, but knowing that we think in this respect also that the careful looking after by attendants is far better for the training of all classes and both sexes under natural conditions than is government by stone walls.

Then, *again, the schools to be recognised by the Education* Department are not to have more than 60 children altogether. Now, it has been hinted at in the beginning how the minds of epileptics are altered by the disease and how various must be the means of education, how numerous must be the classifications, and how many teachers there must be to instruct each classified group in a school of only 60 children. The necessary teaching would be most unnecessarily expensive under such restrictions. Some classes would only consist of two or three children and in all cases the classes must be necessarily small. But if we had a larger number of children to group we could then manage to give each teacher the full number of children who can be taught together and so limit the expense in a reasonable way. At the same time we would be able to maintain the necessary amount of emulation in large classes that could not be kept up if the number in each class were too small.

We are looking at the matter from a practical point of view. We have no rates to fall back upon, and the regulations which I have described really put it out of the power of philanthropic institutions to overtake the education of the children according to the rules of the Education Department. But teaching the children as well as the adults is a therapeutic measure *We believe that it tends to the recovery of* the children that they should be educated, and for this reason we are retaining our school unassisted by the Education Department. We think, however, that an unnecessary obstacle has been placed in our way and that institutions having the care of epileptics have been discouraged where they should have been encouraged.

Liverpool.

# A SHORT CONTRIBUTION TO THE STUDY OF GENERAL INFECTIONS PRODUCED BY THE STAPHYLOCOCCUS AUREUS AND BY THE STREPTOCOCCUS.

BY DR. GIUSEPPE BELLEI,
BACTERIOLOGICAL LABORATORY OF THE BOARD OF HEALTH OF BOLOGNA (ITALY).

THE general infections produced by the pyogenic micro-organisms (staphylococcus and streptococcus) are well known; there is therefore no necessity to speak of them in general. But the narration of particular cases is always, I think, of great utility because in them it is often possible to find some interesting feature. For this reason I wish to describe briefly some cases that have come under my notice in *the course of my practice. Two of these, which I* published in an Italian medical journal, *Il Policlinico*, in 1898, were caused by the staphylococcus aureus.

CASE 1.—The first of these two patients was a medical man who suffered from a spot of chronic eczema behind the left ear This spot was very irritable and he was constantly scratching it, sometimes producing excoriations. One day he opened an abscess on the arm of a female servant and then went to disinfect his hands, but on the way he scratched the spot behind his ear. Two days afterwards he noticed near this spot a very red painful swelling which rapidly became larger and more painful and his temperature rose to about 102° F. A surgeon who was called in three days afterwards made a deep incision in the phlegmon, but very little pus came out. The wound was dressed frequently during the ensuing week and appeared to improve. In spite of this the general state of my patient became worse and worse and his temperature continued very high (from 102° to 104°). It was *not possible to find a local condition* adequate to account for this high temperature, so I supposed that a general infection had resulted from this abscess. A vein of one of his arms was punctured in order that a bacteriological diagnosis might be made and at the same time care was taken to isolate the micro-organism which caused *the abscess in the woman In both cases I found* the staphylococcus pyogenes aureus in pure culture. Some days afterwards small abscesses were observed in different parts of the male patient's body, all of them being caused by the staphylococcus pyogenes aureus. The only internal lesion that he presented was a serous pleurisy, in which I found, not the staphylococcus aureus, but the staphylococcus albus The abscesses that I opened, some of them as large as a man's fist, from the beginning to the end of the illness were about 60 in number The patient's temperature remained always very high and he died in two months with symptoms of cardiac paralysis.

The woman had many other abscesses in different parts of her body after the one in her arm, but she made a good recovery and it is necessary to observe that except for the pain caused by some large abscesses she was always free from fever or other complications and was able to attend to her work

From this case two inferences may be drawn 1. Considering that the staphylococcus pyogenes aureus produced in the woman only abscesses, whilst in the male patient it produced a general infection, which ended in his death, it appears evident that this result was due not to the inherent and necessary virulence of the micro-organism but to the special conditions of the male patient, imparting to the staphylococcus a virulence which it did not possess in the case of the female patient. 2. Laboratory investigations tend to demonstrate that the staphylococcus pyogenes albus is only an attenuated form of the staphylococcus pyogenes aureus. Now, the male patient was affected during his illness by a pleurisy which was serous and which always remained so, and I found in this serous exudation only and constantly the staphylococcus pyogenes albus. Hence when it is remembered that in every part of the body of the patient purulent lesions and the staphylococcus pyogenes aureus were found, it is permissible to suppose that the pleura possessed the faculty of attenuating this staphylococcus pyogenes aureus, which by virtue of this attenuation became converted into the staphylococcus albus and was no longer able to generate pus.

CASE 2.—The second of these two cases was that of a boy who was wounded by a nail in the right leg. Three days afterwards an abscess, which was opened at once, appeared at the seat of injury. In spite of this operation I noticed 48 hours afterwards that there were some abscesses on the boy's body and that he presented symptoms of meningitis. He died in six days. Blood withdrawn from one of the veins of his left arm contained the staphylococcus pyogenes aureus in pure culture.

This case was not of very great importance, but I have related it because it is useful to compare it with the preceding one. Both were cases of pyæmia, because I observed the formation of abscesses in each of them. But the course of the disease was very different in the two cases. In the first it was chronic, because the patient died only after two months' illness, whilst in the second it was very acute, death occurring six days after the beginning of the attack.

The two following cases were caused by the streptococcus and, I think, were also very interesting.

CASE 3.—The patient, who was not under my care but under that of other medical men, was a woman who for some years had suffered from a chronic inflammation of the gums and maxillary alveoli with production of pus. She consulted many specialists but did not derive any benefit from their suggestions. At the beginning of last year she caught a cold which was accompanied by pyrexia and was followed some days afterwards by inflammation of the throat and pharynx. The matter appeared to be of little importance at first, but a sudden severe pain in one of her ears, together with the continuance of the pyrexia, caused her medical advisers to suspect suppuration of the middle-ear. These conditions remained without change for some days until the symptoms of mastoid suppuration appeared. She was operated on at once, but a general infection caused by streptococci followed the operation, and as soon as this diagnosis was established Marmorek's serum was used. It, however, produced no effect and the patient died in a week, during which her temperature was always about 105° F.

CASE 4.—The patient was a man, 48 years of age, who had been in good health until the age of 40 years, when he began to suffer from chronic inflammation of the gums and the maxillary alveoli, accompanied by the formation of pus. He consulted many specialists, but no one was able to effect a cure. When he reached the age of 45 years I was obliged to remove his right testicle, because it was found to be affected by tuberculosis. He made a good recovery after the operation and apart from his dental trouble his health was otherwise satisfactory. One day in November last year he had a severe sore-throat, which he did not treat in any way, but went to his business as usual. In the evening he had a violent fit of shivering followed by high temperature and it was obvious that this sore-throat and pyrexia were caused by a phlegmon of the pharynx. In the course of the next few days an abscess formed in the right tonsil. This abscess was opened four days after the beginning of the inflammation of the pharynx; a moderate quantity of pus escaped, and this on cultivation showed the presence of a very small streptococcus and of a saccharomyces, of which I will speak subsequently. After the operation the patient felt very much better, the pain in his throat subsided so that he became able to swallow, and his temperature, which had hitherto been about 100° F., fell to 98°. But about 7 A.M. next day he was suddenly seized with a shivering fit, followed by a rise of temperature to 104°. The suspicion of a general infection produced by one of the micro-organisms that I had found in the pus of the abscess entered my mind at once, and with the view of confirming the diagnosis some blood was taken from a vein of his left arm. In order not to lose time and thinking that the infection was due most probably to the streptococcus I began to use Marmorek's serum. In the first 24 hours 50 cubic centimetres were injected, but the patient's condition grew worse, and his temperature remained permanently high, being always about 104°. The use of Marmorek's serum was continued during the next two days, but in spite of it the patient died from failure of the heart unaccompanied by any localised lesion.

The micro-organism isolated from the blood was a streptococcus which had the same microscopical character as had that found in the abscess. I made experiments on rabbits and guinea-pigs with this streptococcus, with the streptococcus isolated from the pus, and with the saccharomyces. The lesions produced by the streptococcus derived from the abscess corresponded with those due to a streptococcus of moderate virulence, whilst the streptococcus isolated from the blood possessed a great virulence. The saccharomyces injected either into the veins or under the skin, or into the peritoneum, caused the death of the animals. When it was injected into the veins the animals died in 44 hours with lesions of all the organs, especially of the liver and the spleen, which was 10 times larger than normal. After injections into the peritoneum some of the animals died in four or five days from acute peritonitis, others more slowly, without evident lesions, but in a profound marasmus and presenting a little swelling of the spleen. Injections made under the skin had a different result; either the animals died from marasmus with a little swelling of the spleen or else they lost weight for some days and then recovered.

Microscopical examination of the organs of the animals which died after the injection of saccharomyces into the veins showed the presence of many spots of inflammation in which, by appropriate methods of staining, the saccharomyces was found. All the organs, especially the liver and spleen, were profoundly degenerated.

From these last two cases of general infection some important information may be derived.

1. It has been already said that the death of the male patient (Case 4) was caused by the streptococcus, which was found in the blood. It is therefore logical to conclude that the saccharomyces found in the abscess had no influence upon the development of this general infection, but I nevertheless hesitate to adopt this conclusion. Without paying attention to the fact that the streptococcus found in the blood was more virulent than was that cultivated from the pus, because it would be easy to explain this fact by supposing that it acquired this virulence whilst in the tissues of the patient, it must be borne in mind that the abscess was caused, not only by the streptococcus, but also by the saccharomyces, which was very virulent. Had this saccharomyces no influence at all upon the migration of the streptococcus into the blood or had it a share in preparing the way for the streptococcus? Or, in other words, did not the phagocytosis, the natural defence of the living body against micro-organisms, become inefficient on account of the presence of the streptococcus and the saccharomyces acting together, although it might have been efficient if the streptococcus had been alone? I have now only hinted at this question with the view of suggesting that the saccharomyces which are found in the mouth may be dangerous, not only on account of their pathological properties, but also, perhaps, because when they act along with other micro-organisms they render the defence of the body more difficult.

2. Both of the patients, the female (Case 3) and the male (Case 4), had suffered for many years from disease of the teeth accompanied with the production of pus, and Professor Augusto Murri of the University of Bologna, who has had the opportunity in his large practice of seeing many patients, has assured me that he has often in inflammation of the throat seen suppuration of the adjacent lymphatic glands or, what is worse, the occurrence of general infections in persons who were the subjects of chronic disease of the gums and maxillary alveoli attended with the production of pus. What can happen in these cases? To explain these ill-effects following inflammation of the throat in persons suffering from this disease of the teeth it is necessary to admit that the micro-organisms which exist in the saprophytic state in the mouth become virulent when a chronic illness of

the alveoli and gums is present, because in the purulent material that is produced they find a very congenial soil and they thus acquire a certain virulence. In the next place they enter the tissues at points where the local reaction is insufficient to hinder them from migrating into the nearest lymphatic glands, or into the blood, where they cause a general infection. It would be of great scientific interest to test this hypothesis by experiments on animals.

3. In both cases Marmorek's serum was used and it appeared to be without influence upon the course of the infection.

Bologna.

# ELECTRIC SHOCKS AT 500 VOLTS.[1]

BY ALEXANDER PELHAM TROTTER,
MEMBER OF THE INSTITUTION OF ELECTRICAL ENGINEERS

A GOOD deal of misapprehension exists as to the circumstances under which shocks at 500 volts may be felt or the conditions which may lead to serious consequences. The electric pressure of 500 volts has become well established as the standard for electric traction, but apparatus designed for this pressure can be arranged to take another 100 or 150 volts without appreciable alteration. Conditions of commercial standardisation seem to set the limit for working at about 600 volts; and it is fortunate, from the point of view of safety, that no further extension of pressure under ordinary conditions is likely to be needed.

Since in a few cases shocks at 500 volts have been fatal newspapers have not hesitated to argue from the particular to the general and have assumed that all such shocks involve serious injury, if not death. For once they are in good company; the technical press and eminent practical electric traction engineers seem to have a horror of 500 volts. Such horror has its wholesome side, but ignorance brought face to face with imaginary horrors may result in panic. Modern journalistic sensationalism has made the most of the accident which occurred in Liverpool in February, 1901, and such was the scare that months afterwards, when a harmless necessary trolley-wire fell on to a tramcar, passengers, not only jumping to the conclusion that they were threatened with a hideous death, jumped to the ground and sustained serious injuries. Irresponsible correspondents have suggested in the newspapers that to fall on the electric rails of the Central London Railway is to be grilled alive; they knew no better. But when during the inspection of the last extension of the City and South London Railway I stood on the rails in wetted boots, and sat on the live conductor and slapped the running rails with my bare hands, engineers, electricians, railway employés, and others who ought to know better, were surprised, and they spoiled the effect of my demonstration by suggesting that I was peculiarly insusceptible to shocks. A pressure of 300 volts was used at first for electric traction, but when afterwards it was taken up and developed by Americans they settled by *experimenta in corporibus vilibus* that a pressure of 500 volts was high enough for economy and not too high for safety.

The chief object of this paper is to record a few experiments and to discuss the conditions under which shocks at 500 volts are devoid of danger. The subject may be divided into three parts: (1) the physiological and electrical conditions; (2) the dangers connected with trolley-wires; and (3) the dangers of third rails of electric railways.

*Physiological and electrical conditions.*—In dealing with the first part I need but barely allude to physiological matters, but I will refer first to the current, then to resistances, and lastly to pressure. The sensation may be a prick, a pleasant tingle, a hot burning, or a convulsive shock. The sensation does not depend directly on the actual current but on the current density. With four or five square inches (30 square centimetres) of contact between dry metal and bare skin (for example, grasping a trolley-wire) a steady continuous current of one or two milliampères is hardly perceptible.[2] From 3 to 8 are easily supportable, above 10 milliampères is painful, and above 35 almost unendurable. A larger current than 20 milliampères in seldom used for medical applications. Every electrical engineer is familiar with the sharp pricking shock given by a fine wire. In that case the current density is very high, but the current is so small that little else than the tactile nerve-endings in the skin are stimulated. With larger currents and more surface muscular contractions are added to the tactile sensations, especially if the current is at all unsteady. The electrical phenomena of nerve and muscle have been studied by physiologists; they are rather complicated and do not concern the general purpose of this paper. Alternating currents seem to be about four or five times more painful, but the sensation is of a different character. I have no knowledge of the relative danger of alternating and of continuous currents, and no further reference will be made to alternating currents in this paper. It is difficult to make any exact determination of the relation between current density and sensation. More than about 14 milliampères of steady continuous current at the finger-tip, making a poor contact of about one-sixth of a square inch (one square centimetre), is unendurable, but 35 milliampères from boot to boot, nearly the whole of the soles of the feet being in contact, is much less painful. Under prolonged shock the current increases owing to a fall of resistance, but that does not concern accidental shocks.

Passing now to resistances, the resistance from finger-tip to finger-tip on dry metal and under 100 volts is about 20,000 ohms. It varies a little with the volts, decreasing at higher pressures. Two coins nipped in the terminals of an Evershed ohmmeter serve very well for electrodes. This finger-tip resistance is of considerable importance in connexion with accidental light contacts at high pressures. The resistance is almost all at the skin. The thin skin on the inside of the wrist is much more sensitive than that of the palm of the hand The difference between the resistance from finger to finger of one hand and between one finger of each hand is inappreciable The resistance from hand to hand when grasping two pieces of dry trolley wire is about 5000 ohms; different individuals vary a good deal, probably owing to the dryness of the skin; I have found it as high as 14,000 The resistance between the body and the earth or an iron rail through the sole of the foot, stocking, and boot, is of considerable importance in connexion with electric railways I find that the resistance from boot to boot, the boots being dry and without nails, varies from 45,000 to more than 200,000 ohms. The lowest of measurements on 25 different persons made with 500 volts gave 25,000 ohms. Boots worn into holes and wetted by walking on wet pavement gave only 13,000. The values for resistance of the human body given in medical works are of little use for the present purpose, for care is taken as a rule to facilitate the passage of the current. "Under conditions of medical practice, and using moistened electrodes, the resistance of the body, when the skin is well wetted with warm water, is about 2000 or 3000 ohms—that is to say, an electromotive force of 12 volts (eight Leclanché cells) will pass a current of four to six milliampères."[3] Most of the measurements of resistance which I have given were made with from 100 to 500 volts and are calculated from the milliampères which passed. Taking the information which I have already given about the effect produced by various currents it follows that the mere touching of dry metal at 100 volts, finger to finger, gives hardly any sensation, but with a larger contact a shock is felt. At 200 volts a light touch gives an unpleasant prick, but the current through a firm contact is about from 12 to 18 milliampères, which most people can bear without considerable pain, especially if the contact be gradually made and broken There is no after effect; the sensation is very similar to that of heat. To grasp with bare hands two pieces of metal at 500 volts would give a very painful shock, but a light and quick touch is no worse than the shock from a half-pint Leyden jar, an experience more familiar to schoolboys than to

---

[1] A paper read before the Institution of Electrical Engineers on Feb. 27th, 1902.

[2] If this paper be read, as I hope it may, by others than electricians it may be well to explain that one ampère of current passes through a resistance of one ohm when the electrical pressure is one volt. One milliampère, or one thousandth of an ampère, passes through a resistance of 1000 ohms when the pressure is one volt, and one milliampère passes when the resistance is 100,000 ohms and the pressure 100 volts, and so on in proportion.

| Volts. | Milliampère | Ohms. |
|---|---|---|
| 1 | 1,000 | 1 |
| 1 | 1 | 1,000 |
| 100 | 1 | 100 000 |
| 500 | 5 | 100 000 |

[3] Lewis Jones: Medical Electricity, p. 194.

engineers. A 500-volt shock may be described as worse than touching a kettle of boiling water, not so bad as touching a red-hot poker, about the same as touching a soldering iron at working heat, or as when an inexperienced blacksmith's boy picks up a black-hot horseshoe. These shocks are common incidents in the daily work of a careless linesman; nearly all those who are practically engaged in electric traction work receive more shocks than they like, but they agree that they might reduce the number by taking more care. This is an important measure of the severity of such shocks, and perhaps the only one which will be appreciated by those members of the public who do not care to try for themselves In such brief shocks the muscular sensations probably mask the contact sensations, but a bad 500-volt shock burns the skin.

Cases of fatal accident from 500 volts are so rare that the conditions can only be guessed at. If the skin resistance be reduced by moisture, especially if salt or chemicals be present, and if the contact be large and prolonged, 100 volts may be fatal. While repairing an arc lamp in a steam washing factory at Bradford in 1899 a man is said to have been killed by a shock at 225 volts; a fatal accident occurred in Germany with about 300 volts; but a man may be choked by a crust of bread under exceptional conditions. The death of a man by blood-poisoning arising from a burn caused by a short circuit on the Central London Railway in December, 1900, does not concern us; a death occurred on the Metropolitan Railway in Paris, when a platelayer fell and remained fallen on the third rail of 500 volts. But the case to which so much attention has been drawn and which has caused such a scare is the accident in Pembroke-place, Liverpool. Instead of the present system of well-earthed guard wires an attempt was made to keep fallen telegraph wires from touching the trolley wire, and the attempt was unsuccessful. Nearly 50 wires fell in a tangle across the street and lay on the trolley wire, which did not break The passers-by in the street upon whom they fell escaped with a few shocks. It was dark and snowing and a salted slush lay on the street. Two men walked blindly into the wires and were entangled, and, struggling, became entangled the more The current was not cut off for nearly half-an-hour. Here was a lamentable combination of seven circumstances: (1) the unusual conditions of weather, the snow freezing to the wires as it fell; (2) failure of the wood strip (which is still extensively used on the continent) to act as a guard; (3) the large number of wires, the long span (375 feet), and the tangle in which they fell; (4) the salt slush of snow in the street; (5) the darkness and invisibility of the wires; (6) failure of the police telephone signal service; and (7) the delay of 25 or 30 minutes before the current was cut off. If anyone of these seven causes had been absent it is probable that the fatal results would not have occurred. It is practically impossible that such an accident can occur again in Liverpool, for the telephone wires which crossed the tramways have been either diverted, placed underground, or cabled, at a great expense to the corporation, and a considerable number of the postal telegraph wires have been satisfactorily altered. I am tempted to digress into the question of guard-wiring, but this paper must be confined to shocks, and I hope that the discussion will be similarly restricted.

*Dangers connected with trolley wires*.—Neither the man in the street nor a man on a car runs any risk of taking 500 volts skin to metal. On several occasions during inspections of tramways when a trolley wire has been within reach from the top of a car I have grasped it with both hands, and with more or less difficulty I have persuaded others to do the same. In each case the weather was fine, the car was dry, and no shock, not even the least sensation, was perceptible. To show that there was no trick I have grasped the hand-rail and flicked the trolley wire with a finger; the shock is trifling. It follows, therefore, that if a live trolley wire fall on a crowded car, although it may give alarming flashes when it touches a hand-rail or tramway rail, the chances of a shock on a fairly dry day are nothing compared to the obvious mechanical injuries which might be occasioned Trolley wires do fall and trolley wires are very properly excluded from the leading cities of the world—London, Paris, Vienna, New York, Budapest, &c.—but as yet the damage done by the falls has not been electrical. A trolley-wire is an obvious thing; it sometimes springs back in large coils, but it generally falls and lies still or hangs, and it is regarded with a prudent solicitude which this paper is not intended to remove. But on a dry or frosty day anyone with tolerably good boots may fearlessly touch the live end even if he stand on the rail. I would not publish this statement had I not tried the experiment on some dozen persons, the majority being women and children. My son, seven and a half years old, stood on a rail and played with wires, there being 500 volts between rail and wires. The current was less than one-quarter of a milliampère and he felt nothing. His boots were new. A fallen telephone wire is not so obvious It does not stop the traffic; it is apt to writhe and to coil round a person; should he fall on the rails the short circuit might severely burn him. With wet boots and wet ground the conditions are different. Standing on damp granite setts in rather damp boots, and grasping a trolley-wire, I found that the current was 15 milliampères. The sensation was by no means unendurable; brief touches gave sharp pricks. Standing on a rail increased the current to 20 milliampères. With old boots worn into holes, and after walking a couple of miles on wet pavement, standing on a rail and grasping a trolley-wire gave 35 milliampères. I took this for several seconds, and I should be sorry to take more. I broke contact cautiously by raising the boot on one edge. There was no after effect; the sensation was merely that of heat, as though the trolley-wire were hot. Spilling half a bucketful of water on the ground increased the shock intolerably. I am inclined to attribute this to the better contact between boot and earth rather than to decreased resistance of the earth (in this case granite setts). Three others tried the experiments with me, and as far as we are able to compare experiences I am satisfied that I am not relatively insusceptible to shocks.

Besides the fall of trolley-wires, either on a car or in the street, there are roundabout and unlikely ways in which shocks may be conveyed to unsuspecting persons; for example, a linesman on a ladder, and somehow making a good earth, holding a wire while its broken end or a careless sag touches a trolley-wire; but the discussion of such accidents belongs to the subject of guard-wires.

*Dangers of third rails of electric railways*.—The first time that I stepped on the live rail of a third-rail railway I clutched the engineer lest my legs should give way under the shock, but I felt nothing. I went to where some water stood half an inch deep on a cement floor and "marked time" for two and a half minutes. With caution I stepped on to the live rail and then on to one of the running rails, felt nothing, and then stooped down and touched the running rail while standing with both feet on the running rail. I felt a slight tingle, which my subsequent experiments lead me to think was produced by a current of about six milliampères. To sit on the live rail without touching the running rails was easy, and I cautiously flicked the running rail, then touched it, and then laid my hands flat on it without the slightest sensation In the light of the figures which I have given this is not at all surprising, and I have invited several others to try the experiment, with the same negative result. Of course, the result depends on the dryness of the clothes. The resistance of dry cloth is very high. After walking in the wet for about an hour with sound but not thick shoes I stepped on 500 volt rails and felt nothing, but on touching with the finger I received a smart shock, perhaps 30 milliampères. I have already stated that with old worn-out and wet boots the resistance was only 13,000 ohms. This was found with only 400 volts. Standing on rails in my laboratory, the rails being connected to the outers of the Westminster Company, I could just support the current of about 30 milliampères The sensation was almost precisely like that of standing on hot steam-pipes. It was easy to turn it on gradually by beginning and ending with the edge of the sole. The shock would, of course, be very alarming to anyone who was not expecting it There was no perceptible after-effect. Ordinary nails in the heels of boots make no difference, but hob-nails give uncertain pricking stings which are rather painful, but under no circumstances need they be sustained. Until I tried these experiments I must confess that I did not enjoy the walks which I have sometimes taken in "tube" railways during inspections by the light of oil lanterns, but now, with dry boots, I take no care whatever. It is very desirable that the live rails of third-rail railways should be guarded by planks to prevent short circuits by tools, &c., and to make it less easy for a person falling on the rails to make contact with bare skin. While experience has shown that a person so falling may receive a serious and even fatal shock, this can only occur if he make contact with both a live rail and a running rail with bare skin, or thoroughly wetted clothes, and if he lie there for a time. As to the length of this time we know nothing, but so long as the fall has not injured the person so that he cannot rise it is very improbable that the shock would be maintained. A platelayer in the open-yard of the Waterloo and City Railway once accidentally sat on the third rail and made the circuit through his feet on wet ground; he shouted and was pulled off by his mates; the contraction of the muscles prevented him from rising. He could probably have rolled over and so released himself. He was back at work again in a few minutes.

Numerous accidents to horses show conclusively that these animals are peculiarly susceptible to electric shocks. Electrical conditions under which a human being would receive an unpleasant shock of from 10 to 15 milliampères cause instant death to a horse, and it appears that horses are terrified under conditions where a human being would feel no shock. But it must not be concluded that a given current produces more effect on a horse than on a man. A horse makes excellent contact with its shoes, and these are well connected by nails to its body. It is probable that the resistance is very small and the current very large; but even making this allowance the horse appears to be more susceptible.

*Conclusion.*—The dangers of electric shocks at 500 volts have been much misunderstood, greatly exaggerated, and little investigated. The pressure of 500 volts has been deliberately chosen by electrical engineers because it is not dangerous under ordinary conditions. The conditions under which serious shocks are not produced by 500 volts are discussed in the paper, and it is safe to assume that all shocks more serious than those which are recorded are dangerous. Dry wood and dry boots without large nails offer so great resistance to electric current that it is perfectly safe to touch a trolley-wire while standing on a dry tram-car, or even while standing on the ground or on the rails. Wet weather makes a considerable difference, but boots must be very wet to allow enough current to pass to produce a severe shock Men engaged in electric traction work receive many slight electric shocks at 500 volts, and they might avoid most of them by taking more care Dry clothing offers so great a resistance that no shock can be transmitted through it The peculiar conditions under which shocks at 500 volts have caused death are discussed and are shown to be very exceptional. Experiments have been made on some 30 persons, including 12 women and six children, and it is proposed to make other experiments. With sound dry boots hardly anybody can feel a shock when standing on the live rail of an electric railway with one foot and a running rail with the other. With damp or wet boots a shock is felt, but neither the sensation nor the degree of wetness of the boots can be measured accurately. It is not possible to receive a shock by sitting or lying on a live rail so long as the clothes are dry and continuous—that is to say, so long as the live metal is not touched by the bare skin.

# A CRITICISM ON THE VISUAL TEST AS USED IN THE BRITISH ARMY.

BY A. A. BRADBURNE, L.R.C.P. & S. EDIN., L.F.P.S. GLASG.,
CIVIL SURGEON TO THE CONNAUGHT HOSPITAL, ALDERSHOT.

SEEING the importance which is attached to good shooting under the altered conditions of modern long-range rifle-fire it becomes an important question whether the standard of vision at present in vogue is a sufficiently high one Let us then examine the means adopted for fixing a standard and endeavour to see in what respect it fails.

The visual power of the recruit is tested by means of Professor Longmore's "test dots," which consist of black dots one-fifth of an inch in diameter on a white background, so that by means of a covering card many variations in the number and position of the dots can be obtained This is held up at a distance of 10 feet from the recruit who is asked to count the number of dots exposed. The black dots as seen at 10 feet are supposed to bear the same relation to a bull's-eye three feet in diameter as seen at 600 yards The 10 feet being a convenient distance was first taken and then the proportionate size of the black dot found by a process of simple calculation—viz.: as 600 yards: three feet : 10 feet : one fifth of an inch.

Now let us see what relation this standard of vision bears to normal vision—in other words, what amount of bad sight does it allow a recruit to have in the service. According to Volkmann, the minimum visual angle at which an object can be clearly discerned is one of one minute, and the distance at which such ought to be seen can be easily calculated when we know the size of the object. The size of each dot is one-fifth of an inch, and therefore with a normal acuteness of vision each dot ought to be seen at a distance of 57 feet; but the distance required by the regulations is only 10 feet, or, roughly speaking, a fifth of what good vision ought to consist of. If the other medical requirements were taken on a similar basis the standard of health and strength would be of a very low order This lowness of requisite visual ability is even further reduced by the fact that for militia, volunteers, and departmental corps the dots need only be held five feet away.

Such a seemingly low standard would, one might think, admit into the service men with most inferior vision, without the additional opportunities which such a rough-and-ready method presents for "scraping through" A few statistics taken from notes of over 1000 cases seen by me whilst stationed in Aldershot may show what types do pass the test, the percentages due to "scraping through" being ignored on account of the obvious difficulty of discriminating between them. The state of the refraction was in all cases done under a mydriatic and the following is a fairly accurate summary Out of every 100, 82 were found to be hypermetropic and 18 to be myopic. Of the hypermetropes 16 per cent were found to be over 5 D. and below 10 D. No case of over 11 D. was met with. Of the myopes 2½ per cent. were over 5 D and under 10 D., and 1 per cent. were over 10 D and under 15 D No case of over 15 D. was met with. Of mixed astigmatism the proportion was 4 per cent., and of antimetropia the proportion was 2½ per cent. Thus we see that, roughly speaking, 25 per cent. of the men who complained of inability to see to shoot were justified in their complaints and had been admitted into the service by either too lax a test or by fraud. The proportion is, of course, misleading unless one bears in mind that the cases examined were only those who had made some complaint about their vision, but that such errors of refraction can pass the test dot is plainly shown

This leads us to ask, In what particular respect does the test dot fail? Turning to our figures again we note that it fails to detect first of all fairly high degrees of hypermetropia, secondly mixed astigmatism, and lastly cases of antimetropia and myopia of a degree above 5 D. For practical purposes all cases of myopia of 5 D. or more can be considered as having passed by "unfair or hurried tests." It is different though, in cases of mixed, compound, or simple astigmatism, as unless the degree be very marked but little difficulty is experienced in counting fairly correctly the exposed dots if not too many be shown and it be done in a good light. Again, in cases of high degrees of hypermetropia it signally fails because at the age (18 years) at which the recruit is generally examined nearly all the hypermetropia is latent. It is in this respect alone that for practical purposes the dots chiefly fail. For example, take a recruit with hypermetropia of 8 D, aged 18 years; his accommodation at this age is 10 D, so it is all latent, but test him again in a few years, or at the end of a long march, when his ciliary muscle is weakened, and the hypermetropia becomes manifest, and the result will be very different.

How are we to remedy this? If we move the dots further away he will still be able to read them, and we would be excluding myopes of a low degree of about 2 D. who are of even more use If we bring the dots nearer we admit myopes of a too high degree and may even then admit cases of hypermetropia of over 5 D, which is too high to be of value. If we adopt the plan of finding out the smallest reading type which can be clearly defined we should then exclude the patient with high degrees of latent hypermetropia and in conjunction with the test dots exclude the high myope who could easily pass the reading test. The test dot fails also to diagnose absence of binocular vision, which is shown by the admittance of men with alternating strabismus; but if the recruiting officer were to examine the external appearance of the eyes such would not happen, and, moreover, failure to detect corneal opacities and similar visual defects would not be so often passed over as is so commonly done

What, then, are the advantages possessed by the test dots over Snellen's test letters? They are as follows:—1. The ease and simplicity of the test, especially for men who are unable to read. 2 The reliability with which the test can be carried out by men not specially versed in ophthalmic work. 3 The small compass both of the test itself and the space required in which to use it. 4. By its very breadth of lowness of the visual standard combined with yet a certain limitation causing it to give every chance of obtaining recruits with vision which, though not perfect, is yet capable of being trained to the different branches of the service according to the ability to shoot.

We have seen that the test dots admit men with a certain amount of astigmatism This varies in degree according to the measure of the axis of the meridian with which they have taught themselves to see best. For example, to take five privates: (1) R E $+\substack{+1{\cdot}75\\+3}$, L.E. $+\substack{+1\ 25\\+1{\cdot}25}$; (2) R E. $+\substack{+3{\cdot}5\\-1}$, L E. $+\substack{+1\\+1}$; (3) R E. $+\substack{+6\\+2\ 5}$, L E. $+\substack{+2\\+2}$; (4) R E. $+\substack{+2\ 25\\+1{\cdot}5}$, L E. $+\substack{+1{\cdot}5\\+5}$; and (5) R.E. $+\substack{+4\\+2}$, L E $+\substack{+3\\+2\ 5}$. All the above could count the dots fairly well with the right eye and quite easily with the left and had therefore passed, but no one would deem their right eye as a good "shooting eye" or would have passed them if they had been tested with Snellen's test type.

Hence the question arises, What degree of astigmatism ought to disqualify for further service? and this the ophthalmic surgeon frequently finds that he has to answer when consulted by astigmatic patients who are sent to him on account of being unable to shoot correctly. In coming to an opinion each case must naturally be judged on its own merits, due consideration being given to the age of the patient, but as a general rule the amount of hypermetropia or myopia which exists in addition to the astigmatism is the chief guide to aid one in forming a definite opinion As a rule, high degrees of astigmatism do not pass the test dots, and it is chiefly those at the back of which lie larger errors of hypermetropia or myopia which subsequently cause trouble to the soldier. A bull's-eye, it must be remembered, is not a rectangular figure, and if to an astigmatic soldier the right and left edges appear blurred the top and bottom will have fairly sharp edges, and from these he can take his bearings. It is true that the rifle-sights are linear figures, but here, again, it is his inability, when a high degree of hypermetropia exists, which prevents him focussing them properly, the astigmatism only unless excessive aggravating the condition. Thus a man with H 5 D. $\bigcirc$ H·A. 1 D. is less able to shoot as well as one with H. 1 D. $\bigcirc$ H.A. 2 D., though neither would be considered as ever likely to become crack shots, yet the latter in one axis would be the more likely to have accurate vision, whilst it would not exist in either of the meridians in the former.

Seeing, therefore, that the standard of vision required by the Army Regulations is, roughly speaking, one-fifth below that of perfect vision—we must not forget the fact that very few persons have really perfect eyesight—is it incumbent upon us to raise the standard in view of the importance now attached to rifle-shooting, or should we, on the other hand, improve the vision by artificial means (that is, by spectacles) and thus have a wider field to draw upon for recruiting purposes? The best answer is given by Professor Longmore in his "Manual of Instructions ...... for testing ...... Vision of Recruits." He says: "At first, when the introduction of long-range rifles with graduated aims in place of smooth-bore muskets made it necessary to pay particular attention to the range and acuteness of vision possessed by recruits, efforts were made to obtain recruits with full range and perfect acuteness of vision. But it was found impossible to obtain recruits possessing such qualities of vision in sufficient numbers, and it therefore became necessary to relax the requirements in these respects. ..... In a country in which voluntary enlistment and highly paid wages are the rule it is the object not to accept any who are not fully qualified for the performance of the duties which will devolve on them in the army. And when only one rule exists for all alike evidently the standard for those parts of the army in which a high degree of visual acuteness is a necessity should be chiefly taken into account in framing rules on the subject, in order that the necessary degree of military efficiency may be attained." And in regard to the wearing of glasses he says: "Special difficulties would be experienced if glasses were allowed to be worn in the English army as they appear to be in some parts of the troops of continental armies. These difficulties particularly relate to the want of means of replacing them when injured or broken in many of the distant stations in which English troops are habitually employed. ...... If the glasses were damaged or broken while troops were on active service there would be almost insuperable difficulties in replacing them, and this would just be the time when they would be most urgently required. Moreover, though spectacles may be perfect, when dust, rain, condensed moisture, or other circumstances interfere with the transparency and therefore with their utility, accoutred infantry soldiers carrying rifles, or mounted troopers, are too fettered to be in a position to remove these impediments as they occur, and the spectacles would cease to be of any advantage."

These opinions of Professor Longmore carry the same weight to-day as they did in 1875 when they were written, but seeing that the test dots admit into the service a few who are unfit to shoot well unless provided with glasses the important question arises, Are we to remove such from the army or retain them in the service and provide them with glasses? The plan I adopt under such circumstances seems to me to be the best way out of the difficulty. If the disability be not such as totally to unfit the soldier and he has had a fairly long training in the service—this point being the one to which chief attention is paid—he is given a prescription for glasses and sent back to his regiment with advice to get permission to be allowed to use them when shooting or at other suitable occasions. If his commanding officer values the soldier this permission is generally readily granted and suitable duties are found for him; on the other hand, should his regiment not consider him worth retaining he is returned to hospital and then discharged. In all cases, too, in men who have but recently joined the service in whom visual defects are found of such a nature as will prevent them ever becoming efficient shots it is always considered advisable to recommend their discharge as being unlikely ever to make efficient soldiers.

It will be seen from the above that, on the whole, the present means of testing the vision for admittance into the army is, though a low standard, yet sufficiently high for all practical purposes, if properly carried out; also that a small percentage of men unlikely ever to become efficient escape its test, and that such can subsequently be detected and got rid of by being referred to an ophthalmic surgeon.

Aldershot.

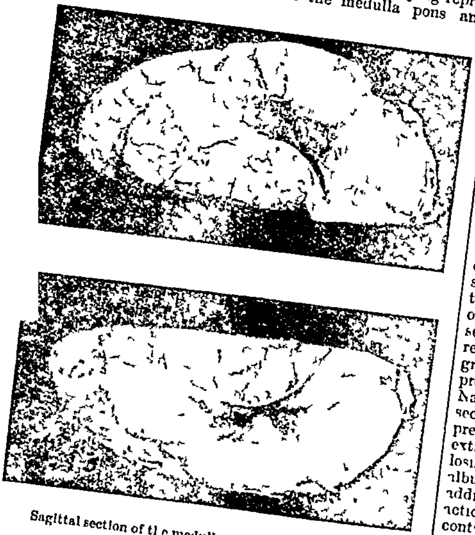
## A CASE OF PRIMARY HÆMORRHAGE INTO THE FOURTH VENTRICLE.

By HOWARD W. REYNOLDS, M.B., B.Sc. LOND.,
HOUSE SURGEON TO THE RAMSGATE GENERAL HOSPITAL.

THE case detailed below is chiefly of interest from a pathological point of view and on account of the comparative rarity of the condition.

The patient was a woman 35 years of age, who was admitted to the Ramsgate General Hospital on Jan. 9th, 1901, suffering from Bright's disease, with hydrothorax and œdema of the lungs. On Feb. 4th she was violently sick in the evening, and on the next day, at 3 P.M., she suddenly developed bilateral paralysis of the lips, tongue, and pharynx, so that she could not articulate properly, protrude her tongue, or swallow except with difficulty, while saliva dribbled from the mouth. There was no headache or any other premonitory symptom except perhaps the vomiting and consciousness was perfect throughout. There was no paralysis of the limbs or ocular muscles. The most marked feature was the defect of articulation which really drew attention to the condition, the defect being inability to pronounce the labials; thus, she pronounced "grapes" as "grace," and "sponge" as "sunge." The temperature rose from 97·2° F. in the morning to 102 6° in the afternoon, and the pulse, which had been slow, rose to 120. These symptoms remained the same until Feb. 7th at 11 A.M., 44 hours from the first symptom, when respiration suddenly ceased, the heart beating for some minutes afterwards.

*Necropsy.*—At the post-mortem examination the right kidney was in the "large white" condition, the left being atrophied. The pleural cavities contained fluid and the lungs were œdematous. The left ventricle was hypertrophied, but the heart was otherwise normal. The brain was found to be healthy except for a hæmorrhage into the fourth ventricle which is shown in the accompanying reproduction of a photograph taken of the medulla, pons and



Sagittal section of the medulla, pons and cerebellum.

cerebellum bisected and laid open. It will be seen that the Sylvian iter is free from clot, as were the third and lateral ventricles, showing the hæmorrhage to be primarily of the fourth ventricle. It will also be seen that the blood has ploughed its way into the posterior part of the pons and medulla, where it would involve the nuclei of the cranial nerves but not the pyramidal tracts. Judging from the symptoms, the nuclei affected were those of the seventh, tenth and twelfth, the sixth being unaffected. The sudden death may perhaps have been due to a second hæmorrhage involving the respiratory centre.

My thanks are due to Dr. G. B. Courtney, under whose care the patient was, for permission to record the case.

Ramsgate.

# PRELIMINARY COMMUNICATION ON THE CAUSATION OF THE SO-CALLED "PERIPHERAL REFLEX SECRETION" OF THE PANCREAS.[1]

By W. M. BAYLISS, D.Sc. OXON.,

AND

ERNEST H. STARLING, M.D. LOND., F.R.S.,

JODRELL PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, LONDON, ETC.

(*From the Physiological Laboratory, University College, London.*)

*Introduction.*—It has long been known that the introduction of acid into the duodenum causes a flow of pancreatic juice, and it has been shown recently by Popielski and by Wertheimer and Le Page that this flow still occurs after nervous isolation of the duodenum and the pancreas. Wertheimer also mentions that the flow can be excited by injection of acid into the jejunum but not by introduction of acid into the lower part of the ileum. These authors conclude that the secretion is a local reflex, the centres being situated in the scattered ganglia of the pancreas or in the case of the jejunum in the ganglia of the solar plexus (Wertheimer).

*Results.*—The secretion excited by the introduction of acid into the jejunum cannot be reflex, since it occurs after extirpation of the solar plexus and destruction of all the nervous filaments passing to the isolated loop of jejunum. It also occurs after intravenous injection of 0·01 gramme of atropin sulphate. It must therefore be due to direct excitation of the gland cells by a substance or substances conveyed to the gland from the bowel by the blood stream.

The exciting substance is not acid. Wertheimer has shown that injection of 0·4 per cent. HCl into the blood stream has no excitatory influence on the pancreas. The secretion must therefore be due to some substance produced in the intestinal mucous membrane under the influence of the acid and carried thence by the blood stream to the gland. This conclusion was at once confirmed by experiment.

When the mucous membrane of the jejunum or duodenum is exposed to the action of 0·4 per cent. HCl a body is produced which, when injected in minimal doses into the blood stream, produces a copious secretion of pancreatic juice. This body, which for the present we may term *secretin*, is associated with another body with a pronounced lowering effect on the blood pressure. The two bodies are not identical, since acid extracts of the lower end of the ileum produce the pressure-lowering effect but have no excitatory influence on the pancreas. The action of the acid is to split off the secretin from a precursor, *prosecretin*, which is present in relatively large amounts in the duodenal mucous membrane, gradually diminishing as we descend the intestine. The prosecretin is apparently slightly soluble in 0·9 per cent. NaCl solution. It has no influence on the pancreatic secretion. The secretin may also be split off from its precursor by boiling this with 0·9 per cent. saline. The acid extract may be boiled, neutralised, and filtered without losing its activity. The active filtrate contains some primary albumoses and gelatin, which may be precipitated by addition of large excess of alcohol and ether, and have no action on the pancreas. The alcoholic ethereal filtrate contains only a small amount of organic material, but on evaporating to dryness and taking up the residue with water the solution obtained is as active as the original infusion.

These results indicate that secretin is probably a body of very definite composition and of small molecular weight. Dr. Osborne is at present engaged in an investigation of its chemical characters and identity.

A chemical sympathy between different organs has often been assumed as, e.g., between the uterus and the mammary glands, but we believe that this is the first case in which direct experimental proof has been afforded of such a relationship. It is probable, however, that this acid-duodenum-pancreas mechanism will prove to be but one of a whole class of similar mechanisms, the study of which should considerably increase our control of the various chemical functions of the body.

In the light of the results here noted a revision of Pawlow's experiments is necessary. In none of these latter was a possible expulsion of acid from the stomach into the duodenum excluded. We have so far failed to obtain a secretory effect on the pancreas by stimulation of the vagi, and are therefore rather sceptical of the alleged presence in these nerves of secreto-motor fibres to the pancreas. We are continuing our experiments on this and kindred points.

# A CASE OF IMPERFORATE ANUS.

By B. CROSSFIELD STEVENS, M.D., M.S. DURH., F.R.C.S. EDIN.

I WAS lately sent for by a midwife to see a newly born female child who was not expected to survive. The midwife had given the child a dose of castor oil because of the rattling in the throat, after she had done this she discovered that the bowel had no apparent opening. When I saw the child, who was undersized, she was cyanosed; she had evidently inhaled a quantity of mucus and discharge from the maternal passages during birth. On examination the only indication there was of an anus or proctodeum was a small elastic mound. Knowing that the child had been given castor oil I decided to operate at once, so with the help of a fellow practitioner but in a "slummy" room with a bad light I made an incision into the perineum and hunted for the rectum which I failed to find. I was next thinking of doing

---

[1] A paper read before the Royal Society on Jan. 23rd, 1902.

a colostomy when during straining under the anæsthetic I noticed a little meconium exuding from the vulva. This was the first clue to the real state of affairs—i.e., a persistent cloaca between the rectum and the vagina. I then passed a probe into the vagina which went horizontally backwards about one-third of an inch above the perineum and then upwards into the rectum. After this a pair of pressure forceps was passed through the vagina into the bowel and the rectal walls were pushed before it into the opening which I had made in the perineum. This was opened on the point of the forceps and was sewn with continuous catgut sutures to the anal skin. I could now pass a probe from the perineum into the bowel, also from the vagina into the bowel; meconium came at once through the new anus, and the first stage of the operation was completed. On the second day a little packing was put in the vagina and all the meconium then passed per anum. The child was still very cyanosed and a quantity of mucus was expressed from the bronchi. On the third day the wound was perfectly healthy and meconium was passing per anum, but the child had not been given any nourishment and was cold and cyanosed. This was due partly to the inability of the child to swallow, indifference on the part of the mother, and lack of attention on the part of the friends. On the fourth day the child died from, as I thought, septic-aspiration-broncho-pneumonia and inanition.

I think that from a surgical point of view the case is one of interest. The reason of failure to find the rectum at first was because it was drawn abnormally forward and was ill-developed. The lesson which the case teaches is that in a case of imperforate anus the medical attendant should always examine for a fistula between the rectum and the genito-urinary organs.

## WESTMINSTER HOSPITAL.

### A CASE OF AMPUTATION THROUGH THE THIGH IN A CHRONIC DIABETIC WHO HAD NECROSIS OF THE FOOT, FOLLOWED BY A DISAPPEARANCE OF THE GLYCOSURIA.

(Under the care of Mr. W. G. Spencer.)

The desirability of operating in cases of diabetes has been doubted. For instance, Erichsen wrote: "Saccharine diabetes is another constitutional condition which absolutely forbids all operations except those required for the immediate preservation of life."[1] This is probably true of the severe acute cases, but in cases of chronic diabetes operations, such as amputation of a gangrenous limb, may be performed with safety, as Mr. R. J. Godlee showed in a paper read before the Royal Medical and Chirurgical Society.[2] As in the case recorded below, the sugar may disappear from the urine when the diseased limb has been removed; this has already been shown by Mr. W. G. Spencer.[3]

A woman, aged 61 years, was admitted into the Westminster Hospital on Nov. 8th, 1901, and left on March 8th, 1902. She weighed about 12 stones; 20 years ago her weight was 19 stones and seven years ago 15 stones. It was some 12 years ago that she first felt a constant thirst, drinking one or two gallons daily; for the last five years the thirst had not been so marked. About Oct. 1st she first noticed a small crack at the side of the nail of the second toe of the right foot whence inflammation spread to the foot and an escape of blood and pus from several openings followed. The foot below the malleoli was much swollen, there were several sinuses, and extensive necrosis was found on probing. Whilst the rest of the patient's circulation did not present any abnormality no pulsation could be detected in the right leg below Scarpa's triangle. For five weeks the patient was treated medically by a special diet and by codeia and the foot was frequently dressed. The necrosis extended but the temperature remained normal. On two days (Nov. 28th and Dec. 13th) no sugar was present in the urine, the patient feeling depressed and being drowsy.

On Dec. 17th amputation of the right limb just below the middle of the thigh was carried out. The superficial femoral artery at this level was completely thrombosed by recent coloured clot and did not show any pulsation after the removal of the tourniquet, but there was free hæmorrhage from all the branches of the profunda artery. A dissection of the limb exposed a general necrosis of the bones of the foot with infiltration of the soft parts by suppuration. The popliteal and the three arteries of the leg were obliterated by sclerosis and thrombi. A microscopical examination showed chronic endarteritis. The thickened intima was much tunnelled by blood channels with calcification of the media. A limited sloughing of the skin-flap occurred along the previous line of the superficial femoral artery and its anastomotic branch, and sugar was present in the urine until Jan. 10th, after which none was found. The patient left the hospital on March 8th. A small granulation patch on the stump still remained to heal, otherwise she felt and appeared in good health.

The accompanying table shows the daily average results of the examination of the urine in the three periods named. The specific gravity and the amount of sugar showed considerable daily variations; the quantity could not often be completely measured. Albumin was never present.

*Table showing the Results of the Examinations of the Urine.*

| — | Before operation—Nov. 8th to Dec. 17th. | Shortly after amputation—Dec. 19th to Jan. 10th. | Convalescence—Jan. 14th to March 7th. |
|---|---|---|---|
| Quantity ... ... ... | 47 ounces. | 43 ounces. | 35 ounces. |
| Specific gravity ... | 1023 | 1027 | 1015 |
| Sugar ... ... ... | 1·6 ounces. | 1·13 ounces. | None. |

*Remarks by* Mr. Spencer.—In the above case arterio-sclerosis and thrombosis were well marked, indicating the necessity of a high amputation, so that the stump might depend for its blood-supply directly upon the branches of the deep femoral artery, the limited sloughing of the flap being connected with the thrombosis of the superficial femoral artery above the level of the amputation. It has been thought that perforating ulcers are the result of a previous neuritis in diabetic cases, but an examination of the nerves of the amputated limb did not support this view. The history that the patient gave was that of septic extension to the foot from a small crack on the toe, rather than of a preliminary perforating ulcer. The arterial changes were as extensive as those met with in cases of gangrene. That this did not happen may be put down to the otherwise good state of the patient's circulation.

As regards the disappearance of the glycosuria (it would be going too far to anticipate the same of the chronic diabetes) a similar result happened in a case in which I amputated the arm as soon as the patient was convalescent. This disappearance of the glycosuria was doubtless aided by the special diet and the codeia, but the medical measures showed their efficacy only after the removal of the incubus caused by the diseased foot.

For the notes and for the many estimations of the sugar I am indebted to Mr. E. C. Johnson, dresser.

## NORTHAMPTON GENERAL INFIRMARY.

### A CASE OF PSORIASIS RUPIOIDES.

(Under the care of Dr. F. Buszard.)

In the more severe forms of psoriasis the treatment often requires to be varied until some medicament is found which is effective. In the case recorded below alkaline baths rapidly removed all signs of disease, though many other forms of treatment had been employed in vain. It is curious that antisyphilitic treatment was useless, for both mercury and iodide of potassium are often of value in psoriasis. Chrysarobin ointment not very rarely requires to be of a greater strength than that used in this case in order to remove the disease. For the notes of the case we are indebted to Dr. W. Bertram Watson, late house physician.

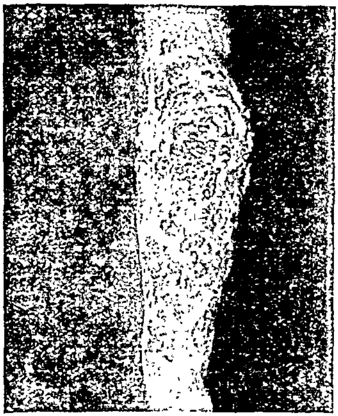
[1] Science and Art of Surgery, ninth edition, p. 7.

[2] The Lancet, Oct. 29th, 1892, p. 994.

[3] The Lancet, June 18th, 1892, p. 1364.

A youth, aged 19 years, was, on Feb. 25th, 1901, admitted to the Northampton General Infirmary suffering from an extensive eruption of the skin. The rash had first appeared on the right arm in June, 1900, and by August had become general. It was irritable for the first two or three weeks and "very scurfy." He had been in good health all the time and had never before suffered from any disease of the skin. No evidence of either congenital or acquired syphilis could be obtained. The accompanying illustrations, reproduced from photographs which were taken on admission, give some idea of the distribution and character of the eruption. It was symmetrical and general, affecting all parts of the body except the hands and feet. It was most marked on the extensor surfaces of the elbows and the flexor surfaces of the knees. (Figs. 1 and 2.) On the trunk, where the eruption was discrete, it consisted of rounded patches from half an inch to one inch in diameter, covered with crust from a quarter to half an inch in depth. The patches were wider at the base than at the apex, thus presenting the typical conical stratified limpet-shell appearance which is so characteristic of rupia. The crusts themselves consisted of epithelial scales and dried purulent matter. The surface beneath the crusts was hyperæmic and moist, and in the case of two or three patches was ulcerated. On the arms the eruption extended on the extensor surface from the wrist to the acromion process, there being no intervening areas of healthy skin. The eruption in this situation consisted of dense horny scales heaped up to a depth of from one-eighth to a quarter of an inch. On removal of these dirty-white scales the base was hyperæmic and moist but not ulcerated The scales were piled up to the same extent on the flexor surfaces of the knees, and on the removal of the scales the same hyperæmic appearance was observed, but no ulceration. The scalp was covered with dry dirty scales, but not to any such extent as in other parts of the body.

FIG. 1

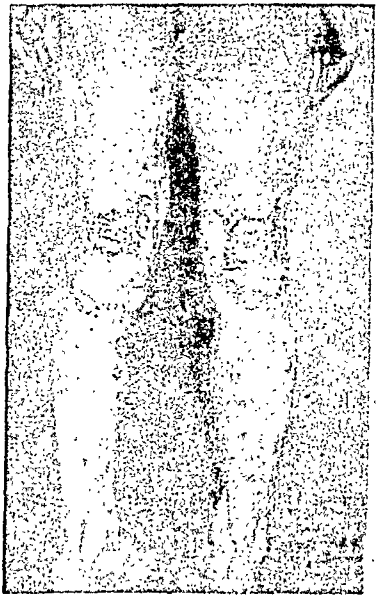


Showing eruption on the extensor surface of the elbow.

One of the most interesting features of the case was the result of treatment. As some of the lesions so closely resembled rupia (although there was nothing in the history to point to the eruption being of a specific nature) antisyphilitic remedies were tried for some weeks internally but without producing any effect. Arsenic was next exhibited, in the form of Fowler's solution, three drops thrice daily after food, but without result; and the same must be said for the internal administration of thyroid extract. Local treatment, which is of such importance in the treatment of psoriasis, was given an extensive trial. The scales were first removed by means of hot water and soft soap, poultices, &c. As the process was not intense at the commencement of treatment, but inclined to be chronic, stimulating remedies were used. Chrysarobin was applied in the form of an ointment (15 grains to one ounce at first and afterwards increased to 30 grains to one ounce) to the arms and legs, and was given a trial of seven weeks, at the end of which time no progress could be reported. Among other ointments tried may be mentioned cream of zinc (one ounce of olive oil, one ounce of oxide of zinc, one ounce of lime water, and two drachms of lanolin), compound sulphur ointment, and compound tar ointment.

On July 12th, after a period of active treatment in the hospital extending over 19 weeks, the condition was practically the same as on admission. If treatment directed to the removal of scabs was discontinued, even for a short time, the arms and legs soon scaled over again. Alkaline baths were then tried. The patient was soaked for half an hour every day in a bath of water at a temperature of from 95° to 100° F. in which four ounces of bicarbonate of soda had been dissolved to about 30 gallons of water. After coming out of the bath he was not dried but glycerine was well rubbed in for a quarter of an hour or 20 minutes, after which he was dusted with zinc oxide powder. Immediately after this treatment he went to bed so as to avoid risk of cold. The result of this treatment was remarkable. In the course of three or four days there was no further tendency to scale, and at the end of a fortnight the whole eruption had completely disappeared, except for a few brown stains on the abdomen, arms, and legs, marking the position of the patches. There are also two or three scars on the abdomen to be seen, due no doubt to the ulcerative process (already referred to) which occurred in the case of a few of the patches.

FIG. 2.



Showing eruption on the flexor surfaces of the knees.

*Remarks by* Dr. WATSON.—The above case is that of an unusual form of psoriasis, similar to those first described by Dr. McCall Anderson under the name of "psoriasis rupioides." I am indebted to the courtesy of Dr. Buszard for permission to publish the case.

# Medical Societies.

## PATHOLOGICAL SOCIETY OF LONDON.

*The Pathology of Diabetes.—Effect of Suprarenal Extract on the Pulmonary Vessels.—Changes in the Nervous System following Removal of the Thyroid.—Rôle of the Liver and Spleen in the Destruction of Blood Corpuscles.*

A MEETING of the Section of Experimental Pathology of this society was held by the courtesy of the managers at the Laboratory of the Royal Colleges of Physicians of London and Surgeons of England on March 18th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Dr. F. W. PAVY, Dr. T. G. BRODIE, and Mr. RAYMOND L. SIAU communicated the results of their further experiments into the Pathology of the Glycosuria which was produced when Phloridzin was injected into the Renal Artery. Their previous experiments consisted in the perfusion of an excised kidney and a repetition of Zunt's experiment—viz., the injection of phloridzin into the renal artery, which resulted in the appearance of sugar in the urine, phloridzin glycosuria Although these experiments supported, as far as they went, the view that the eliminated sugar was produced in the kidney, yet they did not lead to anything absolutely conclusive. The new line of research that they now pursued consisted of the removal in the anæsthetised animal of all the abdominal viscera with the exception of the kidneys. In the operation the liver was removed by ligaturing the bases of the lobes one by one and subsequently excising them. This operation was capable of being performed practically without loss of blood and without any marked immediate influence upon the animal. The effect of the operation upon the state of the blood was to lead to a gradual fall in the amount of sugar from the little over 1 per 1000, approximately the normal amount present at starting, to 0·5 or 0·6 per 1000, a point which was reached in about one hour and below which no essential reduction had been found to occur during a further period of two hours. After the injection of phloridzin in such an animal precisely the same kind of fall in the sugar in the blood was observed and the amount of the sugar eliminated rendered it quite impossible that the sugar contained in the blood could be its source, thus demonstrating the insufficiency of von Mering's theory of the mechanism of the glycosuria. The conclusion arrived at by the authors was that the renal epithelium was the essential factor in the production of phloridzin glycosuria. In both pancreatic diabetes and phloridzin glycosuria there was a parallelism between the sugar and nitrogen eliminations, showing that the sugar was derived from proteid katabolism, but various facts pointed to the sugar formation occurring in the latter case solely in the kidney and in the former in the general system. It seemed probable that under the influence of phloridzin the renal cells acquired the power of katabolising proteid with the liberation of dextrose in a manner that might be compared with the production of lactose in the mammary gland from proteid matter by the action of the cells of that gland.

Dr. BRODIE and Dr. W. E DIXON demonstrated experiments in the Effects of Suprarenal Extract upon the Pulmonary Circulation, showing that the main effect of moderate doses of this substance was to dilate the pulmonary vessels, although it was known to constrict the vessels in other parts of the body. These were of interest as bearing on the question whether suprarenal extract could act as a hæmostatic in cases of pulmonary hæmorrhage.

Mr. WALTER EDMUNDS made a communication on the Pathological Effects produced on the Central Nervous System by Thyroid Excision in Whole or in Part and by Thyroid Feeding. The observations were based on 12 experiments, three on monkeys and nine on dogs. Of the monkeys one was subjected to total excision of the thyroid and parathyroids, from which the animal died in 112 days. The other two monkeys were fed with very large doses of a thyroid preparation; one died in seven days and the other in 12 days. Of the nine dogs three were subjected to primary total excision of the thyroid and parathyroids; they all had severe symptoms and died (or were killed) in three, six, or 12 days. One was subjected to a partial excision of the thyroid which was followed by chronic symptoms, from which it died in 329 days. Two others also underwent partial excision of the thyroid, but in addition steps were taken to paralyse the secretory function of the thyroid left; these two dogs died in 242 and 271 days respectively In three dogs similar operations were performed, but were followed by operations completing the excision of the thyroid and parathyroids. In all cases pathological changes were found, but they varied much in degree; they were most marked in the thyroid poisoning experiments. The changes consisted in alterations in the pyramidal cells, large and small, which showed chromatolysis, swelling of the cell body, swelling of the nucleus, extrusion of the nucleus, and sometimes total destruction of the cell body, leaving practically a free nucleus.

Dr. W. BAIN described experiments which he had performed to ascertain the Rôle of the Liver and Spleen in the Destruction of Blood Corpuscles. He perfused defibrinated blood through these organs for periods varying from one to three hours. He took samples both before and after perfusion and the following points were determined. The hæmoglobin was estimated quantitatively, counts were taken of the red and white blood corpuscles, the hæmoglobin dissolved in the serum was estimated, the volume of corpuscles was ascertained, and the specific gravity of the blood was determined. Dr. Bain found that the liver destroyed certain red cells—viz., those which were poor in hæmoglobin—and consequently the relative value of the corpuscle was increased after perfusion. The spleen also destroyed red cells, but to a less extent than the liver, the worth of the corpuscle being slightly increased after perfusion. The most striking result of the splenic perfusions was the destruction of leucocytes, the larger varieties being especially affected.

## CLINICAL SOCIETY OF LONDON.

*Arthritis of the Knee-joint.—Malignant Endocarditis giving Widal's Reaction.—Acute Paralytic Dilatation of the Stomach.—Lymphadenoma with Growths in the Skin.*

A MEETING of this society was held on March 14th, Mr. HOWARD MARSH, the President, being in the chair.

Mr. H. W. PAGE, Dr. A. PAINE, and Dr. F. J. POYNTON made a communication on two cases of Arthritis of the Knee-joint.—Mr. PAGE briefly recorded the clinical history of two cases of Non-articular Arthritis in which the effusion, which was considerable, did not subside under the influence of rest, warmth, and local remedies. Their etiology was obscure. In both instances they have been attributed to a slight injury, but the severity and stubborn character of the arthritis made it unlikely that such was the complete explanation. When these joints were aspirated a greenish cloudy fluid was obtained, floating in which were flakes of lymph and leucocytes. Aspiration of the joints was followed by a re-accumulation of the fluid and return of pain, and it was observed that when the arthritis was at its height that the patients were slightly delirious. In both cases recovery had rapidly followed aspiration, together with irrigation of the joints with a 1 per cent solution of carbolic acid. In the second case full doses of salicylate of soda, given after the joint had been treated by aspiration and flushing with carbolic, appeared materially to promote recovery. Mr. Page was of opinion that this form of arthritis, which in its clinical course was unusual, must be the result of an infection of the joint by a micro-organism which had a special affinity for the tissues of the joints, and he drew attention to them now because Dr. Poynton and Dr Paine had demonstrated, isolated, and cultivated such a micro-organism, and had produced experimental results which led to the conclusion that this organism was the exciting cause of the arthritis.—Dr. POYNTON and Dr. PAINE then described the investigation which they had made in the second of the two cases described by Mr. Page Upon two occasions they had found in the exudation numerous small diplococci growing in chains. The exudation contained in addition fibrin and leucocytes which were not necrotic. This diplococcus grew well in pure culture, in an acid medium of milk and bouillon, in bouillon to which ascitic fluid had been added, and on blood agar. The cultural and morphological characteristics were indistinguishable from those of the diplococcus of rheumatic fever Intravenous inoculation into rabbits produced a condition more akin to that which resulted from inoculation with the diplococcus of rheumatic fever than that which resulted from the streptococcus pyogenes—that was to say, multiple arthritis, and in one case valvulitis, resulted without visceral suppurations. The spleen after death was small, and in none of the four experiments that were made did death result from septicæmia. On the contrary, two of the animals recovered completely after showing local signs of infection, and two were killed when the arthritis in each case had existed for two months. Quite independently from Mr. Page they had by bacteriological investigation arrived at the conclusion that the infection was an ususual one, and this investigation pointed to the probability that the condition was more closely allied to a rheumatic than to a suppurative arthritis. The scientific interest of the question lay in the light that such an investigation might in the future throw on the etiology of rheumatoid arthritis and the vexed problem of rheumatic and septic processes. A point which was worthy of note was that many diplococci were present in the exudation. Dr. Poynton and Dr. Paine had found that acute and clear effusions of rheumatic fever were usually sterile both in man and in animals, but nevertheless the diplococcus might be found in the synovial membrane. They thought that the endothelial lining of the synovial membrane was an important barrier to their escape, and that in this case of arthritis this barrier had in all probability been much damaged.—The PRESIDENT remarked that the more he saw of diseases of the joints the more he felt that there was a good deal that was uncertain about them and that there was a great deal yet to learn, so that scientific studies of this kind were most welcome.

Dr. W. HALE WHITE and Mr. W. C. C. PAKES communicated a paper on a case of Malignant Endocarditis giving Widal's Reaction. The case was typically one of malignant endocarditis, the patient dying from cerebral embolism. The blood on June 10th failed to agglutinate typhoid bacilli even in a strength of 1 in 2. On the 20th agglutination was produced with a strength of 1 in 2 and 1 in 20, but not with a strength of 1 in 200. Pure cultures of streptococcus longus were obtained from the blood. On the 29th cultures from the urine collected with every precaution showed the presence of a streptococcus identical with that previously obtained from the blood and a bacillus belonging to the paracolon group. Every attempt which was made to isolate the typhoid bacillus failed. The agglutination test was tried with five different strains of bacilli, and with four a complete agglutination was obtained with a dilution of 1 in 20, and with one partial agglutination was obtained with a dilution of 1 in 200. On Sept. 13th the patient died. Blood which was taken from the heart and the spleen showed the streptococcus longus in pure culture, but no typhoid bacilli could be discovered. The patient never had spots or other signs of typhoid fever, nor were any signs of healed ulcers found post mortem. Thus this was an instance of a patient who, suffering from malignant endocarditis of streptococcal origin without any clinical, post-mortem, or bacteriological evidence of typhoid fever, yet nevertheless developed in her blood serum certain substances which had the power of agglutinating the typhoid bacillus. Dr. Hale White and Mr. Pakes pointed out the clinical importance of this result in considering the diagnosis between typhoid fever and malignant endocarditis and also alluded to the fact that many observers had failed to obtain a Widal reaction in malignant endocarditis. In this particular case the presence of the reaction could not be due to the patient having had typhoid fever previously, for no reaction was obtained when she was admitted. She was treated with various strains of anti-streptococcic serum, but without any good result.—Dr. F. S TOOGOOD referred to the case of a man who inoculated his thumb with septic matter on Feb. 10th This was followed by glandular enlargement and constitutional symptoms with a temperature of 104° F. Subsequently, on March 4th, there was bleeding from the nose and his blood gave Widal's reaction, but on the next day the right shoulder-joint and the tissues around were œdematous and other joints became involved On the 10th the blood again gave Widal's reaction, with dilutions 1 in 10, 1 in 25, and 1 in 50. The patient recovered but he had presented the clinical features of septicæmia although the blood gave Widal's reaction.—The PRESIDENT said that he had seen this case and it was clearly one of septicæmia —Dr. J. W. CARR remarked that the paper raised the question of the value of Widal's reaction.. He referred to the case of a child, aged five years, whose symptoms and physical signs were typically those of acute tuberculosis mainly affecting the lungs, yet the blood tested at the Jenner Institute gave a marked Widal's reaction.—Dr. C. R. BOX said that it was most important to indicate what dilution was used. At first with low dilution he had got reactions with diseases other than enteric fever. 1 in 50 was, in his belief, the most suitable dilution for obtaining the true test in cases of actual enteric fever. Turning to the question of nomenclature, he thought that it would be much better to call this test the agglutinative or serum reaction.—Dr. W. LEE DICKINSON referred to a case of gastric ulcer which was erroneously diagnosed during life as enteric fever on the strength of the agglutinative reaction with typhoid cultures.—Dr. POYNTON remarked that his experience at St. Mary's Hospital led him to the conclusion that although the test was not infallible it was a most valuable guide. A great deal must depend upon the technique and the dilution of the culture and on the particular strain used, and this to some extent diminished the value of recorded cases.—Dr. HALE WHITE, in replying, adverted to the importance of knowing whether the patient had had enteric fever previously. He had known cases in which the attack of typhoid fever had occurred 26 years and 23 years previously. Another point was that different strains differed and several strains should be tried. Clinically a negative result should not be accepted after the fourteenth day of the illness nor until several strains had been tried. It would be interesting to follow up Dr. Toogood's case and see for how long the blood gave the reaction.

Mr. A. E. SEARS read a paper on a case of Acute Paralytic Dilatation of the Stomach which occurred in a medical man, aged 30 years. The disease commenced insidiously with an intermittent fever of obscure origin, and was accompanied by constipation, fæcal accumulation, and progressive loss of flesh. Previously to the dilatation of the stomach phlebitis of the veins of the left leg and iliac region occurred, and later the stomach became suddenly distended, and on passing an œsophageal tube three quarts of a dark green sour-smelling fluid were withdrawn. Vomiting was never present and no peristaltic waves were observed. Complete recovery followed daily lavage of the stomach, and up to the present time, just 12 months afterwards, no recurrence of the disease had taken place.—Dr. C. R. BOX congratulated Mr. Sears on the success of his case. Recovery such as this was rare and so was the absence of vomiting. Was there only acute dilatation here or was there superadded obstruction of some kind? he asked. By experiments on dead bodies he had found that the stomach could be folded up on the duodenum; or, again, it was possible for the mesenteric vessels to be dragged down over the duodenum. He had recently met with an instance of the latter kind in the post-mortem room in which the stomach and duodenum were distended by air. When the mesenteric vessels were cut the stomach almost collapsed. Rectal feeding was not always possible in these cases because sometimes they had intractable diarrhœa.

Dr. W. LEE DICKINSON and Dr. W. J. FENTON gave the further clinical history and post-mortem account of a case of Lymphadenoma with Growths in the Skin. The living patient had been shown at a meeting of the Clinical Society last April,[1] mainly on account of the growths in the skin, the true nature of which gave rise to some difference of opinion. Subsequently anti-syphilitic treatment was adopted but without benefit, and the disease made steady progress in the glands and internal organs, proving fatal in August. Post mortem the glands and spleen were found to be affected with the hard form of lymphadenoma, and there were secondary growths of the same nature in the cerebral dura mater and in the cancellous tissue of the tibia, as well as in the skin of the chest. Inoculation experiments were not undertaken, but microscopically no tubercle was found in any part except the liver, where there was at least one small tuberculous focus. The liver was lardaceous. There had been no evidence of syphilis. The case therefore proved to be one of lymphadenoma upon which tubercle had supervened.

## OPHTHALMOLOGICAL SOCIETY.

*Symmetrical Concentric Folds of the Choroid and Retina in Four Cases of Unusually High Myopia.—Membranous Conjunctivitis with Cases.—Diphtheria of the Conjunctiva with Cases*

AN ordinary meeting of this society was held on March 14th, Mr. W. ADAMS FROST being in the chair.

Mr. R. LAWFORD KNAGGS (Leeds) read a paper on Symmetrical Concentric Folds of the Choroid and Retina in

---

[1] Transactions of the Clinical Society of London, vol. xxxiv., p 243.

Four Cases of Unusually High Myopia. The appearance presented was that of a crescent having a sharp dark edge It was always situated on the nasal side of the disc and at varying distances from it, and when both eyes were affected the condition was symmetrical. It was vertically placed and its concavity faced the disc. It was two, three, or four times the diameter of the disc in height. The condition producing this appearance was a folding back of the choroid and retina upon themselves towards the disc, involving a detachment of both tunics from the sclerotic The dark edge was due to the increased thickness of pigment at the summit of the fold, where it turned round upon itself. Vessels curved round the fold as round the edge of a glaucomatous cup. The appearance had been met with in four cases. Both eyes were affected in three cases, and in the fourth one the eye had been previously lost from accident. The degree of myopia varied from – 18 D. to – 38 D., neglecting astigmatism. In one eye there was a rent on the anterior surface of the fold through both tunics, showing the sclerotic, and the edges were turned towards the vitreous. In another there was a wrinkle of both coats on the nasal side of the crescent and parallel to it. In the 1901 edition of Haab's Atlas (Fig. 79) a very similar appearance is shown, but is described as true staphyloma in a highly myopic eye. The explanation was probably as follows. The anterior attachments of the choroid and retina stretching unduly in consequence of the elongation of the eyeball permitted the two inner tunics to slide back towards the posterior pole, but as they were both nailed to the sclerotic by the optic nerve this sliding movement was checked by the obstruction and led to a re-duplication of the coats within the area over which the obstruction was felt.

Mr. **WALTER H. H. JESSOP** read a paper on Membranous Conjunctivitis, with 13 cases. Membrane was present in all, being of varying appearance and consistence. The bacteriological cultures varied widely; in one only was there any membrane in the throat. The corresponding lymphatic glands were enlarged; fever occurred in about half. No paralytic symptoms followed in any. Eight were proved to be cases of diphtheria, the diagnosis resting on bacteriological cultures. Mr. Jessop repeated a desire previously stated that the term "diphtheritic" should be discontinued and that all the cases should be grouped as "membranous conjunctivitis," subdivisions being arranged for the separate groups according to their etiology.

Mr. **SYDNEY STEPHENSON** read a paper on Diphtheria of the Conjunctiva, based on 43 cases collected in five years at the Evelina Hospital for Sick Children and at the North-Eastern Hospital for Children. 75 per cent. of the cases occurred in children under three years of age and 88 per cent. under the age of four years. They were noted chiefly in the months of January, February, March, and April, especially in the last month, thus corresponding with the incidence of ordinary diphtheria. It was, in his opinion, the same disease. Many cases were traced to infection from faucial diphtheria in the same family or neighbourhood. In many instances the disease occurred subsequently to various exanthemata. Previous affections of the conjunctiva were traced only in five children. 40 per cent. of the cases presented constitutional disturbance. Albuminuria occurred in some and two displayed loss of the patellar reflex. There were seven instances of diphtheria on the skin, affecting excoriated patches and impetigenous sores, which received bacteriological confirmation. Membrane was present in 42 cases and in the remaining case the bacillus was demonstrated. In all the cases of moderate and great intensity the corresponding lymphatic glands were enlarged. In 75 per cent. the disease was unilateral. The cornea was altered in only 13 cases. One patient died and 42 patients recovered. The Klebs-Löffler bacillus was demonstrated in every case and in six cases as a pure culture. Mr. Stephenson insisted on the practical value of an immediate examination of smears of the discharge, stained in methyl-eosine, and the [illegible] of gelatin cultures. The treatment which he recommended was immediate injection of antitoxin (4000 units) and the local application of antiseptics (1 in 5000 [illegible] solution or a 15 per cent. solution of potassium [illegible]) with the application of silver nitrate or the [illegible] to ulcerations of the cornea. Isolation of [illegible] was necessary.

[illegible] and card specimens were shown :—

[illegible] HARTRIDGE: (1) Ectropion of the Uveæ; [illegible] of the Conjunctiva.

[illegible] and [illegible] A. BRADBURNE (introduced): A case of Gunshot Wound of the Head, with Partial Motor Paralysis and Hemianopsia.

Mr. H. **WORK DODD**: (1) Sarcoma of the Orbit; and (2) Calcareous Tumour of the Orbit.

Mr. J. **HERBERT FISHER**: Retinitis Circinata.

Mr. J. B. **LAWFORD**: Early Changes in the Retina following Injury.

Mr. J. H. **PARSONS**: (1) Pigmentation of the Retina; and (2) Arcus Senilis.

Mr. R. E. **BICKERTON**: Unusual Changes of the Choroid.

---

## LARYNGOLOGICAL SOCIETY OF LONDON.

### *Exhibition of Cases and Specimens.*

A MEETING of this society was held on March 7th, Mr. E. **CRESSWELL BABER**, the President, being in the chair.

Dr. H. W. **FITZGERALD POWELL** showed a case of Complete Recurrent Laryngeal Paralysis in a man, aged 24 years. The patient stated that in March, 1901, he suddenly lost his voice which returned after three months' treatment. In December he again suddenly lost his voice and came under Dr. Powell's care. On examination complete paralysis of the left vocal cord was found. There was an entire absence of any of the usual causes which produce such a paralysis. The patient stated that at the time of the first attack his medical attendant considered that he had influenza. At the present time there was some movement in the cord and the voice had suddenly undergone great improvement.—Sir **FELIX SEMON** considered that the paralysis was originally due to influenza and that some extra vocal effort or a cold would be sufficient to produce a recurrence.

Dr. **POWELL** also showed a case of Hæmatoma of the Vocal Cord in a female, aged 29 years, the symptoms of which were hoarseness and loss of voice coming on suddenly, and there was sluggish movement of the left cord.—Dr. F. **DE HAVILLAND HALL** pointed out that such hæmorrhages often coincided with the menstrual period or some catamenial disturbance.

Dr. **POWELL** exhibited a modification of Mackenzie's Laryngeal Forceps for the removal of growths in the anterior commissure and also Drills for draining the maxillary antrum through the tooth socket.

Dr. F. **WILLCOCKS** showed a case of Paralysis of the Left Vocal Cord symptoms of which had been present since last Christmas. There was no history of syphilis nor were there signs of any intra-thoracic pressure.—Dr. **DE HAVILLAND HALL** thought that although there were no physical signs paralysis was probably due to the pressure of an aneurysm.—Mr. P. R. W. **DE SANTI**, Sir **FELIX SEMON**, and Dr. J. **DONELAN** instanced cases in which the paralysis of the left cord had preceded any other signs of an aneurysm.

Mr. H. **BETHAM ROBINSON** showed a case of Laryngeal Stenosis due to cicatricial contraction in the inter-arytenoid region in a young man, aged 20 years, who complained of difficulty of breathing on exertion. He gave a history of diphtheria some years previously which had left him with an impaired voice. The voice had gradually improved, so that now it was only husky. Examination showed a perforation of the nasal septum, loss of the uvula, and a cicatricial web passing between the arytenoids. There was no history of syphilis —Sir **FELIX SEMON** pointed out the importance of carefully distinguishing between true paralysis and loss of abduction due to mechanical causes, as seen in this case.—The opinion of members of the society was divided as to whether the cicatricial web was due to diphtheria or to syphilis.

Dr. A. **BRONNER** showed sections of a Tuberculous Growth of the Mucous Membrane of the Right Middle Turbinal in a man aged 50 years.—Dr. **STCLAIR THOMSON** mentioned that tuberbulosis of the middle turbinate was extremely rare.

Mr. **DE SANTI** showed a case of Tertiary Intra-nasal Syphilis in which the right frontal sinus had been opened twice with negative results in a man aged 48 years. He invited suggestions as to further treatment.—Several members considered that there was probably a sequestrum at the junction of the sphenoid and the vomer and advised that this region should be explored.

Mr. **DE SANTI** also showed a case of Angio-neurotic Œdema of the Right Hand accompanied by attacks of dyspnœa in a woman, aged 26 years. Though examination of the larynx revealed no œdema or abnormal condition he pointed out that cases had been recorded in which death from septicæmia On the contrary, two of the animals recovered completely after showing local signs of infection, and two were killed when the arthritis in each case had existed for two months Quite independently from Mr Page they had by bacteriological investigation arrived at the conclusion that the infection was an unusual one, and this investigation pointed to the probability that the condition was more closely allied to a rheumatic than to a suppurative arthritis The scientific interest of the question lay in the light that such an investigation might in the future throw on the etiology of rheumatoid arthritis and the vexed problem of rheumatic and septic processes A point which was worthy of note was that many diplococci were present in the exudation Dr Poynton and Dr Paine had found that acute and clear effusions of rheumatic fever were usually sterile both in man and in animals, but nevertheless the diplococcus might be found in the synovial membrane They thought that the endothelial lining of the synovial membrane was an important barrier to their escape, and that in this case of arthritis this barrier had in all probability been much damaged.—The PRESIDENT remarked that the more he saw of diseases of the joints the more he felt that there was a good deal that was uncertain about them and that there was a great deal yet to learn, so that scientific studies of this kind were most welcome

Dr W HALE WHITE and Mr W O C PAKES communicated a paper on a case of Malignant Endocarditis giving Widal's Reaction The case was typically one of malignant endocarditis, the patient dying from cerebral embolism The blood on June 10th failed to agglutinate typhoid bacilli even in a strength of 1 in 2. On the 20th agglutination was produced with a strength of 1 in 2 and 1 in 20, but not with a strength of 1 in 200 Pure cultures of streptococcus longus were obtained from the blood On the 29th cultures from the urine collected with every precaution showed the presence of a streptococcus identical with that previously obtained from the blood and a bacillus belonging to the paracolon group Every attempt which was made to isolate the typhoid bacillus failed The agglutination test was tried with five different strains of bacilli, and with four a complete agglutination was obtained with a dilution of 1 in 20, and with one partial agglutination was obtained with a dilution of 1 in 200 On Sept 13th the patient died Blood which was taken from the heart and the spleen showed the streptococcus longus in pure culture, but no typhoid bacilli could be discovered The patient never had spots or other signs of typhoid fever, nor were any signs of healed ulcers found post mortem Thus this was an instance of a patient who, suffering from malignant endocarditis of streptococcal origin without any clinical post-mortem, or bacteriological evidence of typhoid fever, yet nevertheless developed in her blood serum certain substances which had the power of agglutinating the typhoid bacillus Dr Hale White and Mr Pakes pointed out the clinical importance of this result in considering the diagnosis between typhoid fever and malignant endocarditis and also alluded to the fact that many observers had failed to obtain a Widal reaction in malignant endocarditis In this particular case the presence of the reaction could not be due to the patient having had typhoid fever previously, for no reaction was obtained when she was admitted She was treated with various strains of anti-streptococcic serum but without any good result.—Dr F S TOOGOOD referred to the case of a man who inoculated his thumb with septic matter on Feb 10th This was followed by glandular enlargement and constitutional symptoms with a temperature of 104° F Subsequently, on March 4th there was bleeding from the nose and his blood gave Widal's reaction, but on the next day the right shoulder joint and the tissues around were œdematous and other joints became involved On the 10th the blood again gave Widal's reaction, with dilutions 1 in 10, 1 in 25 and 1 in 50 The patient recovered but he had presented the clinical features of septicæmia although the blood gave Widal's reaction —The PRESIDENT said that he had seen this case and it was clearly one of septicæmia —Dr J W CARR remarked that the paper raised the question of the value of Widal's reaction. He referred to the case of a child, aged five years, whose symptoms and physical signs were typically those of acute tuberculosis mainly affecting the lungs yet the blood tested at the Jenner Institute gave a marked Widal's reaction —Dr O R BOX said that it was most important to indicate what dilution was used At first with low dilution he had got reactions with diseases other than enteric fever 1 in 50 was in his belief, the most suitable dilution for obtaining the true test in cases of actual enteric fever Turning to the question of nomenclature, he thought that it would be much better to call this test the agglutinative or serum reaction —Dr W LEE DICKINSON referred to a case of gastric ulcer which was erroneously diagnosed during life as enteric fever on the strength of the agglutinative reaction with typhoid cultures —Dr POYNTON remarked that his experience at St Mary's Hospital led him to the conclusion that although the test was not infallible it was a most valuable guide A great deal must depend upon the technique and the dilution of the culture and on the particular strain used, and this to some extent diminished the value of recorded cases —Dr HALE WHITE in replying, adverted to the importance of knowing whether the patient had had enteric fever previously He had known cases in which the attack of typhoid fever had occurred 26 years and 23 years previously Another point was that different strains differed and several strains should be tried Clinically a negative result should not be accepted after the fourteenth day of the illness nor until several strains had been tried It would be interesting to follow up Dr Toogood's case and see for how long the blood gave the reaction

Mr A E SEARS read a paper on a case of Acute Paralytic Dilatation of the Stomach which occurred in a medical man, aged 30 years The disease commenced insidiously with an intermittent fever of obscure origin, and was accompanied by constipation fæcal accumulation, and progressive loss of flesh Previously to the dilatation of the stomach phlebitis of the veins of the left leg and iliac region occurred, and later the stomach became suddenly distended, and on passing an œsophageal tube three quarts of a dark green sour smelling fluid were withdrawn Vomiting was never present and no peristaltic waves were observed Complete recovery followed daily lavage of the stomach, and up to the present time just 12 months afterwards, no recurrence of the disease had taken place —Dr O R BOX congratulated Mr Sears on the success of his case Recovery such as this was rare and so was the absence of vomiting Was there only acute dilatation here or was there superadded obstruction of some kind? he asked By experiments on dead bodies he had found that the stomach could be folded up on the duodenum, or, again, it was possible for the mesenteric vessels to be dragged down over the duodenum He had recently met with an instance of the latter kind in the post-mortem room in which the stomach and duodenum were distended by air When the mesenteric vessels were cut the stomach almost collapsed Rectal feeding was not always possible in these cases because sometimes they had intractable diarrhœa.

## OPHTHALMOLOGICAL SOCIETY.

*Symmetrical Concentric Folds of the Choroid and Retina in Four Cases of Unusually High Myopia — Membranous Conjunctivitis with Cases — Diphtheria of the Conjunctiva with Cases*

AN ordinary meeting of this society was held on March 14th Mr W ADAMS FROST being in the chair

Mr R LAWFORD KNAGGS (Leeds) read a paper on Symmetrical Concentric Folds of the Choroid and Retina in eliminate the fallacy arising from erroneous diagnosis, for if a case were found on admission to have been wrongly diagnosed it was excluded from the report, whereas with those treated at home such correction was obviously impossible and they appeared as cases which did not spread. As to the relative advantages of hospital and home treatment, the case mortality among 4251 cases in hospital was 3·93 per cent and among 228 alleged cases treated at home 5·58 per cent.

---

[1] Transactions of the Clinical Society of London, vol

After some remarks by Mr. T. ROBINSON (Leicestershire), Dr. H. E. ARMSTRONG (Newcastle-on-Tyne), and Mr. H. BEALE COLLINS (Kingston-on-Thames),

Dr. MILLARD defended his own tables and cast doubts on some of Dr. Kaye's inferences, though he fully admitted the importance of local and social conditions. He denied having wished to compare Preston and Warrington except as members of groups and regretted not having excluded, as he had intended, towns where notification had been partial or for short periods only. He could not admit that neglect of hospital provision was evidence of a lighter incidence of scarlet fever, for Swansea was a proof of the contrary. Dr. Kaye's paper had at any rate shown the urgent necessity for further inquiry. Referring to Dr. Malet's important investigations he observed that "it stood to reason that when the first cases were removed the chances of other children contracting the infection would be less."

Dr. KAYE, replying, justified his minute comparison of Warrington and Preston as involving the essence of the dispute, and criticised the inclusion by Dr. Millard in one group of towns that on his own principle properly belonged to another, for under such circumstances averages were worse than worthless—in fact, deceptive. Dr. Millard had, in his closing sentence, conceded the very point at issue and the benefits to the community of hospital isolation. But he could not refrain from deprecating Dr. Millard's indiscretion in having given the publicity of a congress to views the soundness of which was, to say the least, unproved, but which had made such an impression on some local authorities that but for his intervention several towns in Yorkshire would have seriously considered the expediency of closing their hospitals.

## CHELSEA CLINICAL SOCIETY.

### *Discussion on the Nature, Origin, and General Principles of Treatment of Cancer.*

THE adjourned clinical debate of this society was held at the Jenner Institute of Preventive Medicine, Chelsea-gardens, S.W., on March 18th, Dr. C. A. MORRIS, C.V.O., the President, being in the chair.

Sir WILLIAM MITCHELL BANKS said that he would confine his remarks very definitely to certain points in the discussion on cancer. He spoke not from statistics but from an experience lasting over 35 years. He considered that statistics were very dangerous things to manipulate; they could be worked about in various ways, and he knew of no condition that more required a man to go into his upper chamber and say earnestly to himself that he must act honestly than when he was making a statistical table. There was a good deal of impressionism which imbued a man's mind after he had seen many things and his remarks that night would be more a case of impressionism than statistics. It was two years since he had given in the Lettsomian Lectures a general review of their existing state of their knowledge of cancer. Had anything been learned since then? He was sorry to say that nothing of any moment had occurred to increase their knowledge of the subject, referring especially to cancer of the breast. They were, in fact, pretty much where they were two years ago except possibly in regard to the employment of electricity, and the question was whether that was likely to act in a curative manner or not. In regard to the increase of cancer it was now universally admitted that in all civilised peoples there had been a notable increase in the amount of cancerous disease. The last defence of the opposite view was probably made by Dr. Arthur Newsholme in 1899 who argued that the so-called increase in cancer was more apparent than real and was due to better diagnostic skill producing more accuracy in death certificates and to the greater frequency and accuracy of necropsies in hospitals. However, the great mass of statistics accumulated by almost every civilised nation had been too much for Dr. Newsholme's views, which, in his opinion, were untenable. Sir William Banks said that his experience of 35 years pointed distinctly to the fact that cancer was beginning to attack younger people. He was absolutely certain that cancer now made its appearance at a much earlier period of life than it formerly did. Statistics showed that while there was a notable increase of cancer in both sexes, in the case of the male sex the increase had been greater than in the case of the female. Another point which had to be considered was, could anything be positively put forward as a great, broad, and general reason for the cause of cancer? There was, of course, the relation of cancer to geographical situation—namely, that it was most prevalent in the neighbourhood of rivers that periodically overflowed and low, damp situations, especially those with a clay soil. The parts that showed the least amount of cancer were high situations, especially those with a chalk formation. The difficulty was that no one professed to know how all this came about. He himself had only been able to recognise one cause as standing out prominently from among the many that had been suggested, and that was the great increase in the amount of food, and notably of meat, which was now consumed by civilised people. The increase in cancerous disease probably did not date further back than about 40 years ago. In the medical periodicals of 1850 they would not find anyone writing about the increase in the amount of cancer; it was only during the last generation that that point had come up. They had therefore to inquire what might be the notable changes in the life of civilised men that were likely to produce this increase in cancer. It was not drunkenness, because a most common form of cancer was that which affected the female breast, and he had seen nothing in the many patients who had been under him to indicate that drunkenness was connected with it. Syphilis could not be the cause, because among all the women whom he had seen with cancer of the breast he could hardly remember one whose character was bad. It could not be bad water, bad housing, or bad sanitation, because there was hardly any great city which did not now possess an abundant supply of good water and where sanitary affairs were not properly supervised. They had, therefore, to seek for some great change in the lives of civilised people which could not be a matter of doubt, and which must have some notable effect on their physical well-being. In his opinion that change was the great increase in the amount of animal food consumed at the present time. The wretched half-starved patient was not the most prone to cancer; its most numerous victims were well-nourished persons with plenty of fat and often with the colour of health in their cheeks. It was Mr. Moore of the Middlesex Hospital who had said that cancer was eminently a disease of persons whose previous life had been healthy and whose nutritive vigour gave them otherwise a prospect of long life. During the last 20 years the importation of animal food from foreign countries had been enormous. The class of persons who ate meat once a week 50 years ago no longer existed; vast numbers of persons eat meat daily and the well-to-do classes eat it three times a day. It appeared to him, therefore, that the increase in the eating of meat had something to do with the causation of cancer. Referring to Dr. J. F. W. Tatham's statistics in THE LANCET of March 15th, p. 745, he said that it was the male who was now beginning to suffer more from the disease than the female in proportion to what used to be the case, and it was to be noted that it was the male who ate the heavy food in ever-increasing quantity, while the female remained much as before in regard to her eating. Opinions varied as to whether there was or was not a cancer parasite. The parasite was said to be a degeneration, but in his opinion that was not so. He thought that there was a special body in cancer very easily recognisable when they were able to appreciate it which, at all events, accompanied cancer. Mr. H. G. Plimmer went all the way from London to Liverpool to defend the parasitic theory and Mr. H. J. Stiles arrived from Edinburgh to denounce it as a degeneration of the nuclei of the epithelial cells. He did not consider that Mr. Stiles had proved his case. It had to be remembered that the growing part of a carcinoma was its circumference, and the centre was hard—that is to say, it was the point where fibrous degeneration was going on. In the active part alone the parasites were found, and that seemed to him opposed to the theory of degeneration. Further, in the staining of these cancer parasites the reagents that affected them did not affect the nuclei of epithelial cells. Those were two very strong from suffocation had occurred due to sudden œdema of the larynx.

Dr. H. LAMBERT LACK showed a case of rapidly recurring Papilloma of the Larynx. When first seen the patient had a growth in the right vocal cord which was removed. This was followed by considerable congestion and thickening of both vocal cords which had gradually cleared up. At the present time there was recurrence of the papilloma on the right cord and also two distinct growths on the other cord.

Dr. J. DUNDAS GRANT showed a case of Traumatic Tracheal Stenosis in a girl, aged 22 years, dating from an accident at the age of three years. During the last six months she had been troubled by some dyspnœa.

Dr. G. C. CATHCART showed a case of Rhinorrhœa in a girl, aged nine years, which had existed since the age of two years. Adenoids had been removed and various intracranial operations had been performed and both locally and internally a great variety of drugs had been tried.—Dr. DE HAVILLAND HALL recommended a mustard foot-bath and the administration of atropine and morphia at the commencement of an attack.—The treatment of such cases was further discussed.

Mr. R. LAKE showed a case of Atrophic Rhinitis in which melted paraffin had been injected into the inferior turbinated body with good results. The patient had been under treatment for many years and was so far improved that crust-formation had ceased, but she complained that she could not blow her nose. Mr. Lake had therefore endeavoured to contract the passages by enlarging the inferior turbinate by means of submucous injections of paraffin. These had proved most successful as far as the patient's comfort was concerned.

Dr. H. TILLEY showed a case of Papillomatous Growth on the Posterior Edge of the Vomer. The growth was dead-white in colour, contrasting very strongly with the normal redness of the surrounding structures. He regarded it as a harmless curiosity.

Dr. TILLEY also showed a case of Syphilitic Disease of the Larynx simulating malignant disease. The right vocal cord was motionless on phonation and there was considerable uniform swelling of its posterior half. There was also some ulceration below the cords.

## SOCIETY OF MEDICAL OFFICERS OF HEALTH

### *Scarlet Fever.*

A MEETING of this society was held on March 3rd, Mr. A. WYNTER BLYTH, the President, being in the chair.

Dr. JAMES R. KAYE, medical officer of health of the West Riding, read a paper entitled, "Scarlet Fever: How Far do Statistics Prove or Disprove the Utility of Hospital Isolation?" The paper was for the most part a critical examination of the statistics put forward by Dr. C. K. Millard, medical officer of health of Leicester, last year with the view of showing the failure of hospitals to reduce the prevalence or the mortality of scarlet fever. In one of his tables Dr. Millard had given the attack-rate, case mortality, and death-rate in three large towns isolating 64 per cent. of the cases, and in six smaller isolating 28 per cent. only during the year 1882-99, which showed no appreciable advantage from the better isolation; but Dr. Kaye maintained that though the populations of the groups might be equal the errors arising from disturbing factors, as epidemic cycles, social conditions, &c., would be more marked in the smaller number of communities. If the eighteen-year period were divided into two of nine years each the advantage appeared on the side of the first group in the former, but of the second in the latter period; this division, however, was not fair as regards the period 1891-99 which included two maxima and one minimum of prevalence in the first group of towns, but one maximum and two minima in the second. Each increased its percentage of isolation from 57 and 16 in the former period to 71 and 39 in the latter, and each reaped great advantages, but if the results in the first group were less marked it must be noted that 32 per cent. of the population lived in small tenements of one or two rooms, as against 17 in the second, and in order to equalise the population of each group some towns (as Derby and Halifax) had been included in the latter, though isolating a larger proportion of cases than any of those in the former. Dr. Kaye took 93 towns with an aggregate population of over 10,000,000, which he divided into four groups, A to D, isolating respectively under 20 per cent. from 20 to 50, from 50 to 80, and over 80 per cent. During the years 1891-99 Groups A and D were probably the most uniform in their practice, for otherwise they would have fallen with others that for lack of accommodation or other reasons had carried out isolation to a different extent at different times. The good results obtained by Group D were evident, and if A appeared to have a lower general and case mortality than B and C it was probably due to the milder character of the disease, since municipal activity was generally the result of the severity of the visitations. Dr. Millard in his Table VI. had grouped nine towns isolating over, and nine under, 40 per cent. of their cases, and four with practically no isolation, the second group showing the best results during the period 1890-99. But the table was most fallacious, for he had selected 23 towns only when statistics were available for 93, the population of Group I was double that of Group II., and most of the latter isolated over 40 per cent and should therefore have been included in Group I. One in each of the three groups notified for some time first cases only; Croydon had had isolation since 1895 only, and the social conditions of several were widely different, one only of Group I. in his Table VIII. isolated over 50 per cent, and they therefore could not be fairly described as "good isolators," and there were great irregularities in the practice of different towns. The cases of Warrington among those with, and of Preston of those without, isolation were not comparable, for Warrington was in the centre of a thickly populated district, while Preston stood alone in a healthy open country, while its population having been over-estimated had been increasing slowly and therefore had a smaller proportion of individuals of susceptible ages. The hospital at Warrington was so inadequate that, though overcrowded, many cases had to wait a week or a fortnight for admission and were nevertheless described by Dr. Millard as isolated. Yet Warrington, recognising the advantages of isolation, was about to increase the accommodation while the medical officer of health of Preston complained of being handicapped by the want of a hospital which the authorities had decided on providing, and not without good grounds, for while in 1900 the attack rate, case mortality, and death-rate from scarlet fever had been 4·4 per mille, 6·4 per cent., and 0·284 per mille respectively, they had been 15·4, 4·9, and 0·761 in 1901. In support of his contention as to the better social conditions of the population of Preston he pointed out that while the number of persons to the acre was practically the same, the proportion of dwellings of one or two rooms was but 32 per 1000, as against 88 in Warrington, occupied by 19 and 58 per 100, of the respective populations, while the schools were overcrowded at Warrington, there being but 107 seats for 100 scholars, as against 150 for 100 at Preston, and the proportion of children under 10 years, the susceptible material for scarlet fever, was greater at Warrington—viz., 270 per 1000 of the total population, against 239 at Preston. But though he maintained that the principle of isolation was right the practice and machinery employed were in most places open to great improvement, and the methods of disinfection, &c., should be conscientiously recorded if any sound conclusions were to be drawn as to the degrees of success attained.

Dr. H. MALET (medical officer of health of Wolverhampton) complimented Dr. Kaye on his demonstration of the worthlessness of current statistics of scarlet fever and urged investigation on the methods adopted in the cases of the epidemics of small-pox at Sheffield and Gloucester—i.e., taking account of the conditions of each town and of each house and family involved instead of generalising from the varying prevalence of the disease in the whole country. In Wolverhampton he had for eight years noted the number of susceptible children in every house in which a case was notified. Those from which patients were removed were naturally for the most part the more crowded and therefore unfavourable. Omitting all in which there were no other susceptible individuals he found that in 1753 houses from which first cases were removed 4064 susceptible children were left, while in 228 houses where the patients were treated at home there were 463 such. Of the former only 4·8, but of the latter 28·2 per cent., subsequently contracted the disease, or 95·2 of the former and only 71·8 of the latter escaped infection. Many of both classes were reported simultaneously, but 2·2 per cent. only occurred after the removal of the first cases and 19·2 after non-removal of these first notified. The results of non-removal would be still less favourable could one it had only surprised him how successive governments in this country had not afforded full pecuniary and other facilities for the study of one of Nature's secrets, which would never be given up to mere theorisers or superficial observers. The remarks he was making were to him full of difficulty, because he felt the futility, to use no stronger word, of advancing theories for parasitic bodies, or peculiar fluids, or influences of one cell upon another, which would be easy enough to concoct, but impossible to prove or to sustain. He was confident that pathologists needed a stricter classification of the varieties of carcinoma, and he doubted whether the explanation of the origin of a slowly-growing epithelioma upon the face of an old man was the same as that of a quickly-growing spheroidal cancer in the mamma of a woman. There were reasonable grounds for doubt that the explanation of the causes of that pathological puzzle melanosis were the same as, for instance, a sarcoma growing from the fascia or skin. Regarding the cancerous growths of the skin he was able to assert that their microscopical characters were so peculiar and complex that many years of patient investigation would be needful before even a sensible nomenclature could be arranged. This was especially the case with the varieties of sarcoma. It might be remembered that he published in THE LANCET[1] some years ago a case of a gentleman whose face had been exposed to the rays of a tropical sun and who suffered from multiple ulcerating tumours on his red and freckled skin. Dr. J. Galloway made an elaborate investigation of these and termed them "epithelioma," but he was bound to say that the structure was exceedingly peculiar, and it was most difficult to classify those remarkable growths properly. Then what were they to say of those remarkable instances of spontaneous disappearance of, according to their now limited vision, evident malignant tumours within the abdominal cavities? Some years ago he saw with the late Dr. J. Cavafy a young woman who had ascites and dysphagia—an unusual combination in the young; an exploratory operation was done, and a fine nodulated tumour was found round the œsophageal opening of the stomach. This viscus was bound down and contracted so that it could not be pulled forward to the abdominal wall, and the portal vein was obviously compressed by the growth, which passed across the front of the spine. The ascitic fluid was evacuated and the patient was for some weeks much relieved. She slowly sank and died as expected At the necropsy no sign of ulceration or lesion was found in the stomach and the growth was so bossy and nodulated that it seemed hardly worth examining it. Yet when this was done the growth was not cancer at all. It was well-formed fibrous tissue such as would be seen in a primary scar. He had no doubt had it not been for its mechanical situation that it might easily have disappeared. He had two cases now living of gastro jejunostomy, one over two years, another nearly five years, after the operation. The condition of the stomach at the pylorus was as typical of cancer as it could be, but instead of wasting and dying both those individuals were well and ruddy and no traces of tumours were to be felt. Yet another instance: he had recently operated upon a man for a huge soft "sarcomatous" tumour, apparently springing from the suprarenal or kidney, which filled the abdomen and was so incorporated with intestine as to be hopeless for removal. No one doubted that his end was near He was now walking about in excellent health and no trace of the tumour was to be felt. Those instances, which might be multiplied, showed them, he thought, that a class of growths existed the causation of which must be very distinct from the malignant tumours which they exactly simulated. With regard to cancer of the breast, in which he was particularly interested, one remarkable fact had often struck him, and it was this: why should the mamma have such a monopoly in frequency of spheroidal carcinoma and other glands very similarly constituted escape? Take the parotid and submaxillary salivary glands. Their cellular structure and minute composition were very similar to those of the milk gland. They both had ducts leading to a surface How rare was primary cancer of either of those great glands If cancer were due to a parasite what more inviting situation could be found for its development? The frequency of cancer of the breast at the time when the formative cells ceased their proper function was very suggestive of an error of growth; it was equally suggestive of a parasite seizing upon degenerating tissues and causing their riotous proliferation and ultimate decay. Nothing was of greater importance in their knowledge of morbid growths than the fact that the cells of the secondary growths exactly simulated the cells of the structure in which the primary growth originated. Thus, cancer of the liver secondary to cancer of the intestine showed columnar epithelium, cancer of the axillary glands secondary to "duct cancer" of the mamma showed columnar epithelium, and cancer of the thyroid gland, the deposits, which were distributed secondarily in the bones, so exactly simulated thyroid gland structure that it was difficult to distinguish between them. How strongly did that suggest that the infective element was cellular, not parasitic—or if indeed parasitic, that the parasitic element must be intracellular rather than extraneous. But he thought every impartial mind would allow that there was the closest possible relation between natural formative activity in cells and the growth of a malignant tumour, especially a rapidly-growing sarcoma of bone or fascia. Take the case of a crustacean where a limb had been shed. The formative activity of cells here was far in excess of what they observed in sarcoma, yet they were marshalled in orderly array, and a more or less perfect limb resulted. Let them reflect on the extraordinary cell-development that occurred in the formation of the fœtus. What was the mystery which induced the contact of two microscopical cells and from their contact masses of cells arose and developed into a mass which would exceed any sarcoma? Were not the cells arranged in layers and laminæ and complicated folds, resulting in the elaboration of a complete organism? They were completely ignorant of the laws which governed cell proliferation—for laws undoubtedly there were—and it seemed to him that a more complete knowledge of normal cell development was useful before they could explain abnormal deviations. With regard to their knowledge of the remedial measures for carcinoma, operation free and extensive was doubtless the best at their command—and the best was often bad. He had long ago pointed out in regard to cancer of the breast that everything supported the fact that in certain individuals there was a something inimical to the growth of cancer which prevented or retarded return. It was that fact more than the operation which was responsible for those few but remarkable cases, in the knowledge of every surgeon of experience, where long years had elapsed since operation and still the individual remained well. He could hardly dwell too strongly upon the importance of collection and observation of such cases as those so as to make clinical work and pathological investigation go hand in hand. He feared that the remarks which he had made were rather of a discouraging nature, but really it seemed to him that their energies for many years should be towards investigation rather than discussion. The acknowledgment of ignorance was the first step towards improvement. But he believed and held very strongly that the secret of tumour formation was largely bound up in that mysterious "something" which governed cell development and proliferation, that a study of the origin of the innocent tumours might be of the utmost importance, and that experiments in that direction could only be made by experts working under the best of circumstances, with well-equipped laboratories and proper and adequate financial reward and assistance. The time was happily passing away when their profession was contented to think that subjects of the first material importance could be dealt with by private enterprise, and he only trusted that that discussion might do something towards the furtherance of a *proper investigation* of one of the most mysterious of diseases by proper persons, men who combined scientific observation with accuracy and estimated the value of their own discoveries, and who at all events would not give to the public any flimsy and superficial statements regarding curative measures for this terrible class of diseases until their truth and efficacy had been proved beyond doubt. He repeated his belief that the mysteries of tumour growth were bound up in the mysteries of cell proliferation as illustrated on the contact of the sperm cell with the ovarian cell, and whoever solved a problem like that would throw light on many subjects otherwise doomed to perpetual darkness.

Dr. A BARRY BLACKER, in giving a demonstration of the apparatus used in the present position of x rays and ultra-violet rays in the treatment of cancer, said that the success which had attended the employment of physical arguments against the idea of degeneration but it was a question which was still under consideration. Where the parasites came from, what they were, whether they preceded cancer or followed it were questions that had not yet been answered. Were they blastomycetes, did they belong to the class of yeasts, or to what might be called the animal variety? They were not sure of that. There was a considerable belief that they belonged to the class of the yeasts but he thought that many were now turning round to the idea that the cancer parasite was a form of protozoon. That, however, had not been determined. In regard to the question whether cancer was an infectious disease his view was that if cancer was infectious its infective powers were of the very lowest type. He saw to his great surprise that a great body of German authorities had given it as their opinion that cancer was an infectious disease but he could see no distinct proof of it. If it was such an infective disease some proof should be advanced. It was no argument to say that if you rubbed one cancerous surface against a surface which was uninfected that the growth which would ensue proved the infectivity of cancer, because all that was produced was an epithelioma from constant irritation. If they irritated a mucous membrane for any given length of time an epithelioma could be produced. That sort of argument, in his opinion was extremely ridiculous. It had also been said that there were cases of surgeons becoming infected with cancer but he had never heard of anything of the sort. Surgeons could certainly become infected with syphilis, but he would be interested to hear of a case of a surgeon becoming infected in a similar manner by cancer. He sincerely hoped that more caution would be observed in the pronouncements that pathologists and others might make in the future than had been observed hitherto. Quite recently one gentleman had brought forward some views from which the most important results were expected but the wonderful bodies which he had discovered turned out to be nothing more than cells from the corks of his bottles.

---

[1] THE LANCET, Jan. 7th, 1899, p. 22.

Mr. A. PEARCE GOULD said that at the present time there were two great methods of treatment of cancer or so called treatment the operative and the non operative. In surgical interference the wider and more extensive the operation the greater was the chance of success. But he thought they all met with cases which caused them to make that statement with less confidence. They were however, all agreed that in the main the assertion had much truth in it. Amputation, however, was not curing cancer. It might free a man from his malady to excise an area—it might be a very extensive area—of tissue round a cancer and the malignant process might be stayed, but what ground was there for hoping that operations would ever accomplish all that they wished? By the cure of cancer he meant something quite other than the removal of parts which were affected or might become affected followed by no return of the disease. In saying that he was not in any way calling in question the value of their present surgical methods of treatment of cancer although they left very much to be desired. It had been stated he believed by Mr. H. T. Butlin that if every cancer could be properly operated on when it was of the size of a buckshot or a pea that their results would be different. He thought that that was quite correct, but he feared that that time would never arrive. Nothing was more striking than the complete absence of symptoms in the earlier stages of cancerous disease. Of course in the lip it was seen from the first but if they took the more hidden parts of the body such as the rectum or the uterus it was the experience of all surgeons that the disease had often advanced to a considerable extent before the most careful watchful and intelligent patient had been able to take any notice of it. While they rejoiced at practising surgery at the earliest possible moment in the history of a cancer yet they could not but feel that the time would not arrive when they would see their cancer patients in the very early stages of the disease. In regard to the curability of cancer he asked if there was any ground for thinking that cancer would prove to be curable. They saw such a long and almost constant procession of sufferers from malignant disease going more or less rapidly from bad to worse until death came not only as a welcome but also as a belated guest that he was afraid that there was a tendency to feel that cancer was an incurable disease. He was however quite sure that that was not the case. The cure of any disease was only brought about by the action of physiological processes. All their vaunted remedies only produced their beneficial results by influencing in some way or other the ordinary physiological processes of the body. They were quite unable to introduce any new force into the body and they could only work upon the inherent powers of nature and through those powers. The only hope for the cure of any disease was by observation of the methods in which nature herself dealt with that disease. He therefore thought that it was most important to recognise the fact that cancer sometimes did undergo a spontaneous cure and that the physiological forces of the human body were sometimes sufficient to accomplish the perfect cure of cancer. He would give them instances of the spontaneous repair that did take place in cancer. In the case of a woman with very extensive cancerous disease that had destroyed the left breast with large glands in the axilla and above the clavicle, and with that horribly distressing œdema that occurred in these cases, large areas of epithelial tissue were observed to be healing over the cancerous ulcers. In another patient where no operation had been performed, the whole breast had been destroyed by malignant disease and she was admitted to the hospital with an ulcer of the size of the palm of the hand. There were numerous nodules about the breast in both axillæ and there was also cancer in one lung. She eventually died, but a month before that occurred a blue line was seen round the large ulcer on the chest which spread and entirely healed over the ulcer. Before the patient died it was found on examination that the epithelium of that cicatrix was exactly similar to the epithelium of the surrounding skin. The disappearance of malignant nodules was not uncommonly observed, but he would mention particularly two cases in which quite extensive malignant growths had disappeared. In one the patient was a woman with cancer in the right breast and recurrence in the axilla of the same side and on the side of the neck. The growth was also present in the opposite breast and in the opposite axilla and there were signs of extensive malignant disease in the right lung and spontaneous fracture occurred of the neck of her right femur. She received no special treatment because she was expected to die but she began to mend, the deposits all disappeared the disease vanished, and she had remained well since. That could be regarded as a case in which the ordinary physiological forces of the body had dealt satisfactorily with most extensive malignant disease. The second case was that of a man who was operated on for carcinoma of the left maxilla. A fungating growth recurred in the site of operation and the patient was told that nothing more could be done but he got better and seven months after the recurrence had been noted he was absolutely well without the smallest trace of any malignant disease. In those cases the diagnosis had been confirmed by careful microscopic examination. In order not to be misunderstood he wished to make it clear that in cancer there should be early, wide and efficient removal, but they must not think that that was to be the last word in the treatment of cancer. Some day there would be a better word spoken than that and he sincerely hoped that that day would soon arrive.

Mr. A. MARMADUKE SHEILD said that he was not particularly anxious to speak that evening because personally he had long felt that the medical profession with regard to the causation of tumour growth generally, had been guilty of a great deal of talk a vast amount of theorising and very little real knowledge upon which to act. It had long been his belief that the directions of their study should be towards the causation of the simpler forms of tumour as a preliminary towards the understanding of the more complex varieties. There was scarcely one of them in that room who, if he surveyed his skin, would not see one or more warts and moles upon it. They knew no more of the causation of those simple growths than they did of cancer. Who could tell them why one man's body should be covered with fatty tumours and not that of another? Who could explain the cause of a cancellous exostosis or of a nævoid growth on the cheek of an infant? He had often thought that the diseases of plants especially of trees were well worthy of study in the direction of tumour growth. The excessive formation of cellular tissue around the parasite of the oak gall the enormous excrescences around the trunks of birch trees were of the highest suggestive importance for scientists and laboratory experts. He felt confident that they needed a correlation between accurate clinical observation and pathological and microscopical investigations. The subject was of such immense importance to the whole of mankind that although premature.—Dr. R Milne Murray, the President, and others made remarks on the paper and Dr. Ballantyne replied.

Dr. H. Oliphant Nicholson read Further Notes on the Use of Thyroid Extract in Puerperal Eclampsia and the Pre-eclamptic State. In a previous paper he gave reasons to show how the principal symptoms of the eclamptic state would be explained in terms of thyroid inadequacy. Special stress was laid on the fact that the arrest of the secretion of urine, by allowing the absorption of toxins, led up to convulsions A deficiency of iodothyrin towards the end of pregnancy might result in anuria, and the degree of toxæmia would depend, directly or indirectly, upon the quantity and activity of the thyroid secretion. Thyroid extract was therefore indicated in the pre-eclamptic state and also after the onset of convulsions. In the latter case a large dose of morphia hypodermically was a valuable adjunct to the treatment, as by inhibiting metabolism it stopped the formation of poisons and gave the thyroid gland time to recover itself. Morphia in doses of from half to one grain also completely removed arterial spasm. Details of the administration of thyroid extract in four recent cases were then given. The first case was a primipara who in the eighth month of pregnancy suffered from severe headache, insomnia, scanty urine, and uniform swelling of the hands, face, and body. Two fits occurred and were treated with morphia; after the stupor passed off 10 grains of thyroid extract were given and five grains repeated every four hours. The urine was solid on boiling Premature labour set in and a stillborn child was born about 40 hours afterwards. The patient recovered rapidly. The second patient had suffered from eclampsia in three previous pregnancies; the last had been treated with thyroid extract and she had been told to place herself under treatment early in any subsequent pregnancy. In her fourth pregnancy she began taking the thyroid extract on her own initiative at the third month. She had felt altogether different in this pregnancy, had had no sickness, no swelling of the face or body, and no giddiness, blindness, or headache. The urine was secreted in normal quantity and did not contain any albumin. Her labour was not yet due. Thyroid treatment in the third and fourth cases also gave good results. Dr. Nicholson reasoned from the experience noted that it was wise to push the thyroid extract till some symptoms of thyroidism were induced. He did not think that the relaxation of the renal vessels with consequent diuresis could account for the removal of all the other symptoms and believed that the thyroid extract acted somewhat as a specific in favouring metabolism in some unknown way.—Dr. Haultain, Dr. Murray, Dr. S. McVie, and others discussed the paper.

## ROYAL ACADEMY OF MEDICINE IN IRELAND.

### Section of Surgery.

*Swallowing of Metallic Denture.—Hypertrophy of the Prostate.—Suprapubic Prostatectomy.*

A meeting of this section was held on Feb. 28th, Mr. T. Myles, the President, being in the chair.

Mr. G. Jameson Johnston read a paper on a case of Swallowing of a Metallic Denture successfully treated by the internal administration of cotton-wool. The patient, a man, aged 20 years, whilst swimming in the open sea was struck in the face by a wave He immediately felt a choking sensation, was unable to swim on his breast, and made his way to the shore by swimming on his back. Some of those on the shore slapped him on the back to displace the false teeth that he told them were choking him; the first slapping on the back produced dyspnœa. He became black in the face; a further slapping on the back got rid of the dyspnœa, though it caused him much pain. On admission to hospital a probang was passed and the patient experienced so much relief that it was felt that the denture had passed into the stomach. Soon afterwards pains in the pyloric end of the stomach were complained of and they continued for some days. Mr. Johnston then decided on treating him with sandwiches containing a thin layer of cotton-wool in each. A week after admission he was given one and a half drachms of compound liquorice powder which acted as an aperient and got rid of the denture which was found rolled in cotton-wool in his fæces.—Mr. J. Lentaigne confessed that he would not like to take cotton-wool under any circumstances, as he thought that it would not be without risk of producing obstruction. The case illustrated the well-known danger of small dentures. All the accidents resulting from artificial teeth getting into the pharynx were due to small dentures, which he thought should be prohibited, for a large plate could be made for any case calling for artificial teeth.

Mr. R. H. Tobin read a paper on the treatment of Senile Hypertrophy of the Prostate. He traced the interdependence of the prostate gland and the testis and their correlation. In the choice of radical methods he pointed out the value of the presence or absence of sexual desires as an indication. If these were present the case was probably one of true hypertrophy, to be treated by vasectomy or castration; if they were absent tumours causing pressure atrophy of the prostate probably constituted the enlargement and enucleation would effect a cure The failure of vasectomy in certain cases he considered to be due to the non-inclusion in the resection of the filaments of the hypogastric plexus that accompanied the artery of the vas deferens, these being the most direct sympathetic link between the testicle and prostate. Of the radical methods he advocated complete enucleation of the gland as practised by Mr. P. J. Freyer.

Mr. E. H. Taylor read a paper on Suprapubic Prostatectomy. He pointed out that the aim of suprapubic prostatectomy should be: (1) to remove *en masse* and by a process of enucleation those portions of the enlarged lateral lobes which lay beside the urethra and exerted a compressing influence upon it; and (2) to remove the enlarged middle lobe in the same manner, seeing that its action in a large percentage of cases was to obstruct the bladder outlet. He said that suprapubic prostatectomy as practised at the present day remained in its essential details the operation of McGill and of the Leeds school, it aimed at enucleation of encapsuled growths and met all the requirements of the case. He went on to state that a remarkable paper appeared in the *British Medical Journal* some months ago and another quite recently under the authorship of Mr. Freyer of London, in which he related certain cases of *total removal of the prostate and its capsule.* Mr. Taylor, however, had no hesitation in saying that Mr. Freyer was labouring under a misapprehension. Were total extirpation carried out what would it mean? It would of necessity involve the removal of the prostatic urethra, to which there adhered in these cases a varying amount of prostatic tissue and which remained connected with the common ejaculatory ducts. These were displaced downwards and backwards with their surrounding tissue and constituted important supports of the prostatic urethra after the adenomatous masses had been enucleated. Total extirpation would also imply the detachment from its surroundings of the interfibrous investment of the prostate as well as of the thinned cortex. Now this would be not only a totally unwarranted procedure, but in the highest degree dangerous, as it would inevitably mean the laceration of the veins of the prostatic venous plexus which lay in close contact with the interfibrous layer which Mr. Freyer alluded to as the prostatic capsule. This fibrous layer was very tough, whereas the encapsuled masses were of a much softer and more friable consistency. The result was that when the finger was introduced through the incision in the floor of the bladder it found its way, following the direction of least resistance, between the tough investment of the prostate or greatly thinned cortical layer and the encapsuled mass, and this was the true explanation of the ready manner by which the enucleation of enormous tumours might be carried out. Mr. Freyer, however, had, no doubt, extended the scope of McGill's operation and in this respect had succeeded in making a decided advance in this department of surgery.—The President congratulated the section on the interesting papers which had been read — Mr. Henry Gray Croly thought that German anatomists had really added nothing to Alcock's description of the anatomy of the gland.

North London Medical and Chirurgical Society.—A meeting of this society was held on March 13th, Dr. E. Clifford Beale, the President, being in the chair.—Dr. A. Whitfield showed: 1. A case of Figurate Seborrhœic Eczema in a woman. In demonstrating this case Dr. Whitfield said that it was, of course, a common disease, but that the patient before them exhibited a particularly good example of the eruption. The history was that the eruption had spread from the neck downwards during the methods in the treatment of various skin diseases had been followed by the employment of the same or similar methods in the treatment of cancer, more especially of those varieties which were situated in the more superficial positions These methods might be divided into three classes 1 The light treatment associated with the name of Professor Finsen, and introduced by him; (2) the electric brush discharge from any high tension electrical machine, and (3) the x rays The physical data on which Professor Finsen's process was founded were that the light from the sun and from an arc lamp was rich in the most refrangible rays—i e, the blue, violet, and ultra-violet, and that these were destructive to many forms of bacteria, and that the ultra violet rays had but little penetrative power—for most substances the penetrative power increased with the wave lengths, extremely short waves had scarcely any penetrating power at all As far as it was at present possible to determine it would seem as if the electrical brush discharge method of treatment presented much the same features as Finsen's It differed, however, in the source from which the rays were derived An electrical brush discharge was a powerful source of invisible ultra violet and visible violet and blue rays with a small admixture only of heat rays, for the chemical rays given off acted like light on a photographic film, they were concentrated by a lens, and were reflected and concentrated by a concave mirror They converted oxygen into ozone and they set up fluorescence in barium platino cyanide and other salts Moreover, they produced a reaction on the skin resembling that produced by the sun or an arc, which differed from the reaction produced by x rays in being produced quickly and healing quickly instead of appearing slowly and healing slowly The employment of the brush discharge had advantages owing to the absence of heat rays and the presence of violet rays without the admixture of all wave lengths, but it was complicated by the ozone given off and by the products of electrolysis which must be generated to some small extent in the skin from the decomposition of sodium chloride, &c The physical data on which the treatment by means of x rays was founded differed essentially from the foregoing methods With all of them it was possible to destroy bacteria, but under the x rays many of them flourished The same complications of ozone and electrolytic products besides the brush discharge from the tube were present as in the electric treatment but the great penetrative power of the x rays marked a wide distinction between them and the violet At first sight it did not seem probable that those which passed through the body could be capable of producing effect and it would seem more possible that effects might be produced by some of the rays which were absorbed The well known action on the skin produced by the x rays and variously described showed that alterations and destruction of cells might be produced and the difference in the onset and in the result from that obtained from the violet rays demonstrated that a difference existed in their actions It would appear therefore, that there were various rays which might be utilised in the treatment of cancer, violet rays which penetrated the tissues only to a small extent and were bactericidal and produced some tissue change, the x rays which penetrated the whole of the body and produced tissue destruction but were not bactericidal, and mixed rays which could be produced by various methods, it did not seem unreasonable to suppose that rays might be isolated which might be found capable of destroying bacilli or acting upon various cells in different parts of the body

## EDINBURGH OBSTETRICAL SOCIETY

*Exhibition of Specimens —The Premature Infant —Thyroid Extract in Puerperal Eclampsia*

A MEETING of this society was held on March 12th Dr JAMES RITCHIE the President being in the chair

Specimens were shown by Professor A R SIMPSON Dr F W N HAULTAIN, Dr D BERRY HART, and Dr N T BREWIS.

Dr J W BALLANTYNE read a paper on the Problem of the Premature Infant The premature infant was born with the skin, skeleton, and organs of a seven months fœtus He was called upon to play the part of a full time infant with the personalia of a fœtus and was suddenly forced into surroundings of a kind which imposed upon him urgent calls to which he was little able to respond Some cases met these new requirements with wonderful adaptability, but many succumbed, being unable to maintain a physiological equilibrium in their unexpected environment Some survived but progressed into life with a baneful debility The premature infant differed from the immature fœtus in the possession of viability—that was, being capable of an independent existence outside the mother's uterus This period varied, as the state of the maternal health during the pregnancy had great effect upon the vitality of the infant The seven months' fœtus of a healthy mother might survive when the seven months' fœtus of a syphilitic parent might be absolutely non viable The period of viability depended, not only upon the number of months spent in the uterus, but also upon the character of the life of these months The date of probable viability had changed owing to the recent improvements in the management of the premature infant. The introduction of the incubator and the exclusion of sepsis had already pushed back the age of viability to an earlier period, and with further knowledge it might be possible in the future to rescue the lives of infants of earlier prematurity In considering the anatomy of the premature infant they found the weight of a seven months' fœtus varied from three to four and a half pounds and in length was about 16 inches The skin was delicate and transparent, but had lost the bright red colour of earlier fœtal life, there was little subcutaneous tissue so that the face had still a somewhat senile look, lanugo plentifully covered the extensor aspects of the limbs as well as the face and back, and some hair was present on the scalp The nails were thin and did not project beyond the finger tips In the eyes the traces of the pupillary membrane might still be seen In the skeleton nearly all the ossific nuclei which were found in the full time infant were present in the premature one, but they were smaller in size The ossific nucleus in the lower epiphysis of the femur was rarely to be seen, and there was none in the upper end of the tibia, the cuboid, or in the hyoid bone The grey and white matter of the brain could not yet be differentiated The foramen ovale of the heart was still patent and the kidneys were lobulated. The fœtus also had different surroundings, it lived in a hydrosphere instead of an atmosphere and at birth it was separated from the placenta, which was so essential an organ for its existence Dr. Ballantyne then gave an account of the physiology and pathology of the premature infant In the management of the premature infant they must endeavour to create an environment which would, in some points at least, resemble the intra uterine nidus The incubator was accordingly utilised the temperature being kept constantly above that of the infant's body, and in it the patient could be protected from light and injury The infant could not be surrounded by imitation liquor amnii, but a moist atmosphere could be obtained by hanging a wet sponge inside the incubator The incubator should also be kept as nearly aseptic as possible For food the best was mother's milk if obtainable, or if not pre-digested nutriment; and it had sometimes been found of advantage to pass it directly into the stomach through a tube or to drop it into the mouth with a dropper But the intra uterine nutriment of a fœtus contained more iron than there was in the mother's milk it appeared advisable, therefore, to give iron, and the best form seemed to be liquor ferri peptonatus giving it in five-minim doses thrice daily If the mother had no milk asses' milk might be obtainable, if not cow's milk carefully sterilised could be given every one and a half hours in not more than four teaspoonfuls at a time The amount of sugar should be limited As to the exact modification or dilution of the milk opinions varied, some gave the full strength The treatment of the premature condition also involved the awakening or strengthening of dormant or insufficient functions This applied to pulmonary respiration, some artificial assistance in the establishment and strengthening of respiration being very helpful Prevention of prematurity was the ideal management and much could be done in this direction in combating syphilis alcoholism, &c For the infant born prematurely as a result of obstetric interference would always require attention The problem of the premature infant was also enhanced by the steady fall in the birth-rate in the British Isles and colonies as well as in foreign countries In England and Wales in 1871 the birth rate was 34 7 per 1000, it had fallen to 29 3 in 1899, to 28 9 in 1900, and as low as 28 5 in 1901 It was evident therefore that there was a pressing need to conserve the lives of infants even although premature.—Dr. R MILNE MURRAY, the PRESIDENT, and others made remarks on the paper and Dr. BALLANTYNE replied.

Dr. H. OLIPHANT NICHOLSON read Further Notes on the Use of Thyroid Extract in Puerperal Eclampsia and the Pre-eclamptic State. In a previous paper he gave reasons to show how the principal symptoms of the eclamptic state would be explained in terms of thyroid inadequacy. Special stress was laid on the fact that the arrest of the secretion of urine, by allowing the absorption of toxins, led up to convulsions. A deficiency of iodothyrin towards the end of pregnancy might result in anuria, and the degree of toxæmia would depend, directly or indirectly, upon the quantity and activity of the thyroid secretion. Thyroid extract was therefore indicated in the pre-eclamptic state and also after the onset of convulsions. In the latter case a large dose of morphia hypodermically was a valuable adjunct to the treatment, as by inhibiting metabolism it stopped the formation of poisons and gave the thyroid gland time to recover itself. Morphia in doses of from half to one grain also completely removed arterial spasm. Details of the administration of thyroid extract in four recent cases were then given. The first case was a primipara who in the eighth month of pregnancy suffered from severe headache, insomnia, scanty urine, and uniform swelling of the hands, face, and body. Two fits occurred and were treated with morphia; after the stupor passed off 10 grains of thyroid extract were given and five grains repeated every four hours. The urine was solid on boiling. Premature labour set in and a stillborn child was born about 40 hours afterwards. The patient recovered rapidly. The second patient had suffered from eclampsia in three previous pregnancies; the last had been treated with thyroid extract and she had been told to place herself under treatment early in any subsequent pregnancy. In her fourth pregnancy she began taking the thyroid extract on her own initiative at the third month. She had felt altogether different in this pregnancy, had had no sickness, no swelling of the face or body, and no giddiness, blindness, or headache. The urine was secreted in normal quantity and did not contain any albumin Her labour was not yet due. Thyroid treatment in the third and fourth cases also gave good results. Dr. Nicholson reasoned from the experience noted that it was wise to push the thyroid extract till some symptoms of thyroidism were induced. He did not think that the relaxation of the renal vessels with consequent diuresis could account for the removal of all the other symptoms and believed that the thyroid extract acted somewhat as a specific in favouring metabolism in some unknown way.—Dr. HAULTAIN, Dr. MURRAY, Dr. S. MCVIE, and others discussed the paper.

---

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## SECTION OF SURGERY.

### *Swallowing of Metallic Denture.—Hypertrophy of the Prostate.—Suprapubic Prostatectomy.*

A MEETING of this section was held on Feb. 28th, Mr. T. MYLES, the President, being in the chair.

Mr. G. JAMESON JOHNSTON read a paper on a case of Swallowing of a Metallic Denture successfully treated by the internal administration of cotton-wool. The patient, a man, aged 20 years, whilst swimming in the open sea was struck in the face by a wave He immediately felt a choking sensation, was unable to swim on his breast, and made his way to the shore by swimming on his back. Some of those on the shore slapped him on the back to displace the false teeth that he told them were choking him; the first slapping on the back produced dyspnœa. He became black in the face; a further slapping on the back got rid of the dyspnœa, though it caused him much pain. On admission to hospital a probang was passed and the patient experienced so much relief that it was felt that the denture had passed into the stomach. Soon afterwards pains in the pyloric end of the stomach were complained of and they continued for some days. Mr. Johnston then decided on treating him with sandwiches containing a thin layer of cotton-wool in each. A week after admission he was given one and a half drachms of compound liquorice powder which acted as an aperient and got rid of the denture which was found rolled in cotton-wool in his fæces —Mr. J. LENTAIGNE confessed that he would not like to take cotton-wool under any circumstances, as he thought that it would not be without risk of producing obstruction. The case illustrated the well-known danger of small dentures. All the accidents resulting from artificial teeth getting into the pharynx were due to small dentures, which he thought should be prohibited, for a large plate could be made for any case calling for artificial teeth.

Mr. R. H. TOBIN read a paper on the treatment of Senile Hypertrophy of the Prostate. He traced the interdependence of the prostate gland and the testis and their correlation. In the choice of radical methods he pointed out the value of the presence or absence of sexual desires as an indication. If these were present the case was probably one of true hypertrophy, to be treated by vasectomy or castration; if they were absent tumours causing pressure atrophy of the prostate probably constituted the enlargement and enucleation would effect a cure The failure of vasectomy in certain cases he considered to be due to the non-inclusion in the resection of the filaments of the hypogastric plexus that accompanied the artery of the vas deferens, these being th most direct sympathetic link between the testicle an prostate Of the radical methods he advocated complet enucleation of the gland as practised by Mr. P. J. Freyer.

Mr. E. H. TAYLOR read a paper on Suprapubic Prostatectomy. He pointed out that the aim of suprapubic prostatectomy should be: (1) to remove *en masse* and by a process of enucleation those portions of the enlarged lateral lobes which lay beside the urethra and exerted a compressing influence upon it; and (2) to remove the enlarged middle lobe in the same manner, seeing that its action in a large percentage of cases was to obstruct the bladder outlet. He said that suprapubic prostatectomy as practised at the present day remained in its essential details the operation of McGill and of the Leeds school, it aimed at enucleation of encapsuled growths and met all the requirements of the case. He went on to state that a remarkable paper appeared in the *British Medical Journal* some months ago and another quite recently under the authorship of Mr. Freyer of London, in which he related certain cases of *total removal of the prostate and its capsule*. Mr. Taylor, however, had no hesitation in saying that Mr. Freyer was labouring under a misapprehension. Were total extirpation carried out what would it mean? It would of necessity involve the removal of the prostatic urethra, to which there adhered in these cases a varying amount of prostatic tissue and which remained connected with the common ejaculatory ducts These were displaced downwards and backwards with thei surrounding tissue and constituted important supports of th prostatic urethra after the adenomatous masses had be enucleated. Total extirpation would also imply the detac ment from its surroundings of the interfibrous investment of the prostate as well as of the thinned cortex. Now this would be not only a totally unwarranted procedure, but in the highest degree dangerous, as it would inevitably mean the laceration of the veins of the prostatic venous plexus which lay in close contact with the interfibrous layer which Mr. Freyer alluded to as the prostatic capsule. This fibrous layer was very tough, whereas the encapsuled masses were of a much softer and more friable consistency. The result was that when the finger was introduced through the incision in the floor of the bladder it found its way, following the direction of least resistance, between the tough investment of the prostate or greatly thinned cortical layer and the encapsuled mass, and this was the true explanation of the ready manner by which the enucleation of enormous tumours might be carried out. Mr. Freyer, however, had, no doubt, extended the scope of McGill's operation and in this respect had succeeded in making a decided advance in this department of surgery.—The PRESIDENT congratulated the section on the interesting papers which had been read.—Mr. HENRY GRAY CROLY thought that German anatomists had really added nothing to Alcock's description of the anatomy of the gland.

---

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—A meeting of this society was held on March 13th, Dr. E. Clifford Beale, the President, being in the chair.—Dr. A. Whitfield showed: 1. A case of Figurate Seborrhœic Eczema in a woman. In demonstrating this case Dr. Whitfield said that it was, of course, a common disease, but that the patient before them exhibited a particularly good example of the eruption. The history was that the eruption had spread from the neck downwards during the last seven months. The scalp was extremely scurfy, but this had not been noticed and therefore the duration of the disease in this region was unknown. When shown the whole of the chest, the upper part of the back, the upper arms and the forearms, especially on their extensor surfaces, as well as the upper parts of the thighs, were covered with a red, scaly, and slightly scabbed eruption made up on close examination of congested and œdematous follicles. The shape of the patches varied, but all were either round, oval, or poly-cyclical, with very defined edges. Itching was extremely severe but otherwise the health was good. In the axillæ were some small boils probably from secondary infection. 2. A case of very papular Rosacea where the diffuse congestion was almost entirely absent and pustulation was quite unnoticeable. The patient was a woman, aged 36 years, and she had had it on and off for years. There was a fair amount of evidence of dyspepsia, though not of sufficiently painful a type for the patient to volunteer any information about it.—Dr. Whitfield also demonstrated (for Dr. W. A. Milligan) a case of Paget's Disease of the Nipple in a woman, aged 51 years. There had been a discharge from the left nipple on and off since the menopause, which occurred at 45 years of age. 12 months previous to exhibition this discharge became offensive and induced her to consult a medical man. By careful dressing the scabs were removed and the discharge ceased to be offensive, though the nipple became ulcerated and the place never healed, but continued to increase in size. When shown there was an area of about the size of a five-shilling-piece over which the skin was dusky-red and infiltrated but not ulcerated. In this area there were white patches of almost normal-looking skin and this apparent improvement had taken place while the patient had been taking iodide of potassium. The nipple was not destroyed but was considerably smaller and harder than was that on the other side, while at its base there was a small hard mass to be felt which suggested a tumour rather than mastitis. There were also two large and very hard glands in the axilla. Dr. Milligan had sent the patient into the hospital for operation under the care of Mr. G. B. Mower White. Mr. White said that he proposed, in view of the presence of the glands, to remove the breast and to clear the axilla.—Mr. H. S Elworthy showed a woman, aged 24 years, who had suffered from rumbling noises in the stomach since she was 17 years old. Her previous history showed nothing remarkable, with the exception of an attack of typhoid fever. If the patient stood up slight pressure of the left lower ribs caused a loud rumbling and gurgling noise apparently in the stomach. This was often accompanied by the regurgitation of gas up the œsophagus, and occasionally came on without any pressure. The stomach apparently hung much lower than normal, but did not reach up high under the costal margin, suggesting that a slight degree of gastroptosis was present. Mr Elworthy considered that it was probably a gastric neurosis, but discussed the possibility of diaphragmatic hernia and dilated large intestine.—The cases were discussed by the President, Dr. J. G. Glover, Dr. A. W. Wilson, and others.—Mr. White showed a short series of Foreign Bodies found in inflamed appendices, including (1) an Appendix from an acute perforative case in which eight oxyurides were found in the organ; (2) an Appendix from a non-suppurative case in which removal had been practised as a precautionary measure to prevent a second attack and the organ was found to contain five shots and another piece of lead; and (3) a Metal Cap from the end of a pencil which was taken from a fæcal abscess in a boy, and might therefore have been either in the cæcum or in the appendix.

**West Kent Medico-Chirurgical Society.**—A meeting of this society was held on March 7th, Dr. T C Meggison, the President, being in the chair.—The President showed a case of Marked Facial Paralysis.—Dr F S Toogood showed (1) a typical case of Myxœdema on which he was about to commence treatment by thyroid extract; and (2) a young man who after having been knocked down by a cab was supposed to be drunk and was arrested, but was sent to the Lewisham Infirmary. Paralysis of the left side soon supervened. Dr. Toogood trephined over the posterior and anterior meningeal arteries and removed a large clot from the region of the latter. The patient made a good recovery.—Dr. James Donelan read notes of cases in which the postponement of the removal of adenoid masses in the naso-pharynx led to severe aural complications. He pointed out that the recurrence of slight earache and the evidence of Eustachian obstruction furnished by hearing tests afforded a sufficiently distinct warning to enable the practitioner to advise the immediate removal of the growth.—Dr. Morgan Dockrell and the President discussed the paper.—Dr. G. Herschell showed a new Rectal Electrode which could be distended with water while in the rectum and so afforded a larger surface for the passage of the current. He also exhibited and described a High-tension Kidder Induction-coil Apparatus which he considered to be most useful for electro-therapeutics.—Mr. R. V. Donnellan read notes of the case of a woman who had brought about abortion by thrusting a knitting-needle through the walls of the vagina and bladder into the uterus. Septicæmic symptoms ensued and her temperature was 105° F. before the birth of the child. The use of anti-streptococcic serum was followed by immediate improvement and final recovery.—Dr. Peacock (for Dr. P. Scott) read notes of an obscure case in the Miller Hospital, characterised by dulness of one lung, brawny swelling and enlargement of veins over the chest and neck, enlargement of the glands, pyrexia, and coma. The patient recovered with permanent enlargement of the episternal and epigastric veins. Various diagnoses had been suggested, including a gumma, an aneurysm, a malignant growth in the mediastinum, an embolus of the pulmonary artery, and some obscure inflammatory action. There were points against all of these.—Dr. Peacock (for Mr. J. Poland) also showed a specimen of Renal Calculi with Malignant Disease.—Mr. Augustus K. A. Cæsar showed Nine Vesical Calculi of a total weight of 4 ounces 140 grains (the largest individually weighing 7 drachms 50 grains) which had been passed by a woman, aged 70 years, who had suffered for years from complete procidentia.—Dr. J. P. Henry submitted some notes on Dionine as an Analgesic in Eye Diseases. He had tried it both in private practice and at the Italian Hospital in a number of cases of glaucoma, iritis, irido-cyclitis, keratitis, and corneal ulcers, and found that while the superficial anæsthetic action was much inferior to that of cocaine it had a much more prompt and durable analgesic action on deep-seated pain in the eye which was quickly and often permanently relieved. It also favourably influenced the course of those diseases. It could be prescribed together with atropin, eserin, and pilocarpin.

**British Gynæcological Society.**—A meeting of this society was held on March 13th, Dr. J. Halliday Croom, the President, being in the chair.—Various members showed specimens, chiefly Myomata of the Uterus.—Mr. P. J. Freyer (as guest) showed a Myoma which he believed to be the largest intravesical tumour on record removed by a suprapubic incision; it weighed nine ounces and in labour had impeded delivery till successfully pushed out of the way.—The President, in a communication on Suppuration of the Ovary, said that such was almost invariably due to infective salpingitis and was favoured by the presence of a corpus luteum or cyst; an exceptional case upon which h had lately operated showed no intimate connexion betwee the tube and ovary, but a small amount of pus outside th crenated edges of a corpus luteum had led to such persistent pyrexia as was remarkable in view of the absence of fever in connexion with much larger foci in other parts of the body, notably in many cases of pyo-salpinx and pyometra. The patient did well, though for 24 hours she had hæmatemesis with a quickened pulse but no pyrexia. He looked upon hæmatemesis as one of the most serious complications of abdominal work, and in his experience it had been almost always the precursor of death and so closely associated with infection that though its cause was in no way revealed by post mortem lesions he was disposed to attribute it to sepsis rather than to vomiting due to the anæsthetic, handling of the stomach and intestines, thrombosis of the omental vessels after injury or ligature and consequent embolism in the walls of the stomach, or any other cause than had been suggested. It was not confined to abdominal operations and in connexion with general surgery had been very ably discussed by Robert Purves who found it associated with a mortality of 72 per cent. Age was no factor in its occurrence.—Mr. Freyer, in a paper on Stone in the Female Bladder, drew attention to the ease and success with which litholapaxy could be performed in the female, even in very young children, or in the later months of pregnancy; the only special difficulty, escape along the side of the instrument of the indispensable fluid from the bladder, was easily prevented by the pressure of the fore and middle fingers of an assistant's hand on the posterior lip of the urethra. Women recovered from the operation in a day or two and no incontinence was left. He had had most satisfactory results in seven children and 15 adults; one uric acid calculus, weighing two ounces, in a woman 70 years of age he could not crush and it was removed by vaginal lithotomy, but he would now prefer the suprapubic incision; before adopting litholapaxy he had removed stones from three children through the urethra, but incontinence was left in one.—Mr. Spanton showed stones weighing 70 and 180 grains which had been removed through the urethra of very young children and a slate-pencil 2 5 inches long from the bladder of a girl 11 years of age. There was no incontinence in any of these cases, but he concurred with Mr. Freyer that litholapaxy (or, in the case of very large stones, suprapubic lithotomy) was the treatment to be adopted.—The President, Mr. Furneaux Jordan, Dr. Snow, Dr. Travers, and Dr. Macnaughton-Jones also joined in the discussion.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY.**—A clinical evening of this society was held on March 7th, Mr. Alfred Cooper, the President, being in the chair.—Dr. J. B. Ball showed a case of Hysterical Mutism occurring in a man, aged 37 years, who had been completely aphonic since he accidentally fell over a dog in the dark some six months previously. He was unable either to speak or to whisper. Applications of the faradic battery had been used without avail.—Dr. O. F. Grünbaum suggested that the patient should be brought under the influence of hypnotism or of alcohol.—Mr. R W. Lloyd suggested the use of an anæsthetic.—Mr. C. R. B Keetley showed his Extension Splint for the Lower Limbs by means of which active extension could be applied. —Mr. F. Swinford Edwards showed a man, aged 45 years, from whose bladder he had removed a large amount of Villous Growth by suprapubic cystotomy some four months previously. The patient was now in good health and was able to walk four miles a day without discomfort.—Mr. Edwards also showed a case after Transverse Fracture of the Patella. The patient, a man, aged 24 years, broke his patella on Jan. 18th, 1902. 40 hours later Mr. Edwards exposed the joint by an external semilunar flap and united the fragments with silver wire. Gentle passive movement was commenced on the eleventh day and in three weeks the patient was allowed to walk.—Mr. Patmore, Mr. L. A. Bidwell, and Mr. G. E. Twynam discussed the case.—Mr. Bidwell showed two cases of Rodent Ulcer treated by the x rays. In the one the ulcer had completely healed, while the other was still under treatment. He regarded scraping followed by treatment with the x rays as the best method to employ.—Mr. McAdam Eccles showed a man, aged 32 years, whose Right Testis lay in Scarpa's triangle.—Dr. Seymour Taylor showed a case of Obesity. The patient, an omnibus driver, aged 40 years, was abnormally stout and often fell asleep while driving. The organs were healthy with the exception of a feeble heart's action and a little chronic bronchitis. He was much cyanosed, a condition which was increased when he fell asleep and his head hung forward. He had much improved under treatment by venesection and a modified Tufnell diet.—Dr. Arthur Saunders showed a case of Cretinism occurring in a boy, aged 12 years. No trace of the thyroid gland could be made out and the rings of the trachea were distinctly felt. He had been placed on dried thyroid gland for a month in December and again for the last month. In this time he had grown one inch and had lost seven pounds in weight.—Dr. Saunders also showed a case of Organic Nervous Disease which he considered to be tabes dorsalis resulting from congenital syphilis coupled with some intracranial affection of like origin.—Mr. H. W. Chambers exhibited a case of Anencephalus This was accompanied, as was so often the case, by a condition of hydramnios and birth was delayed until the end of the tenth month.

**MIDLAND MEDICAL SOCIETY.**—A meeting of this society was held on March 5th, Mr. Arthur Oakes, the President, being in the chair.—Mr. H. G. Barling showed a woman, 42 years of age, upon whom he had operated three weeks previously for Strangulated Hernia through a slit in the great omentum. The symptoms were moderate vomiting, almost but not absolute obstruction, and a gradually increasing distension of what appeared to be a huge coil of intestine running transversely across the lower part of the abdomen, leading to a diagnosis of volvulus. At the operation it was found that about four inches of the ileum, the cæcum, the ascending colon, and a portion of the transverse colon had become herniated through a slit in the great omentum. A good recovery followed.—Mr. Barling also showed a man, aged 55 years, who came under his care with Chronic Intestinal Obstruction from a broad band of adhesion following herniotomy. The herniotomy had been performed five months previously for a right femoral hernia. The obstruction now existing was overcome by making a lateral anastomosis between the ileum, eight inches from the ileo cæcal valve, and the cæcum by means of a Murphy button one and a quarter inches in diameter. A good recovery followed.—Mr. Christopher Martin showed an Apparatus for obtaining the raised pelvic position in abdominal operations (Trendelenburg position). It consisted of an enamelled iron frame (eight inches high, three feet long, and 20 inches broad) which was placed on the ordinary operating table. The upper end sloped obliquely downwards at an angle of 45°. The patient was placed with the buttocks and legs resting horizontally on the frame, and the lumbar and lower dorsal region of the body on the sloping end of the same. The chest, shoulders, and head of the patient lay horizontally on the operating table. The result was that the pelvis was raised about eight inches above the level of the chest, the spine was in a position of acute lordosis, and the abdomen was inclined at an angle of about 45°. Mr. Martin had used this position for several months in performing abdominal sections and had found it most useful. It was, in his opinion, an improvement on the ordinary Trendelenburg position. The frame was made for him by Mr. Ash, Edmund-street, Birmingham.—Mr. J. Furneaux Jordan showed a specimen of Dermoid Cyst of the Ovary. The patient from whom it was removed made an excellent recovery.—Dr. C. E. Purslow showed a Soft Fibro-Myoma of the Uterus which he had removed by abdominal hysterectomy. The patient made a good recovery.—Mr. George Heaton read a paper on the Treatment of Appendicitis.

**GLASGOW SOUTHERN MEDICAL SOCIETY.**—A meeting of this society was held on March 6th, Dr. John Stewart, the President, being in the chair.—Following upon the reading of the minutes the President announced the gift to the society by Messrs. Fletcher, Fletcher, and Co., Limited, of a framed pair of portraits from their Vibrona Art Series, reproduced in photogravure from the original paintings. These were unanimously accepted. An exhibit was also made of pharmaceutical products by the same firm.—Dr. Robert Pollok then gave an address on General and Medical Experience with the Troops in South Africa. In the course of his lecture Dr. Pollok gave a very interesting and instructive description of his work as a surgeon with His Majesty's forces in the present war. Leaving Bloemfontein, where he saw a great deal of enteric fever, he accompanied the 18th Brigade and was in the midst of the exciting events that befell the march on Pretoria and Komati Port. A detailed account was given of the component parts of the field hospital and the method of attendance on the wounded. The address was abundantly illustrated by a fine series of lantern slides and was greatly appreciated by a large meeting of the society.

**NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.**—A meeting of this society was held on March 5th, Dr. E. C. Kingdon, the President, being in the chair.—Mr. R. G. Hogarth showed the following cases: (1) Extensive Nævus of the Face involving the Palate and the Inside of the Cheek; (2) Tuberculous Peritonitis cured by operation on a congenital hydrocele which existed coincidently—the sac of the tunica vaginalis was studded with miliary tubercles; (3) Spina Bifida cured by excision; (4) a case of Coxa Vara (with skiagrams); (5) an adult one year after Excision of the Knee; and (6) a case of Friedreich's Disease.—The cases were discussed by the President and Mr. Willis, Mr. Jacob, Mr. Hunter, Mr. J Mackie, Mr. Woods. Mr. Mackenzie, and Miss S. Gray.—Mr. Hogarth replied.—Dr. Mackenzie read a paper entitled, "Observations on Post Mortems," and gave an account of four cases observed during life and examined after death. They were as follows: (1) perforated gastric ulcer; (2) aneurysm of the cœliac axis; (3) aneurysm of the transverse aorta; and (4) ruptured kidney.—The paper was discussed by the President, Mr. Hunter, Mr. Woods, Dr. J. F. Blurton, Mr. Hogarth, Dr. A. Fulton, Mr. Mackie, and Mr. Willis.—Dr. Mackenzie replied.

**BRISTOL MEDICO-CHIRURGICAL SOCIETY.**—The sixth meeting of the session of this society was held on March 12th, Dr. Barclay J. Baron being in the chair.—Dr.

last seven months. The scalp was extremely scurfy, but this had not been noticed and therefore the duration of the disease in this region was unknown. When shown the whole of the chest, the upper part of the back, the upper arms and the forearms, especially on their extensor surfaces, as well as the upper parts of the thighs, were covered with a red, scaly, and slightly scabbed eruption made up on close examination of congested and œdematous follicles. The shape of the patches varied, but all were either round, oval, or polycyclical, with very defined edges. Itching was extremely severe but otherwise the health was good. In the axillæ were some small boils probably from secondary infection. 2. A case of very papular Rosacea where the diffuse congestion was almost entirely absent and pustulation was quite unnoticeable. The patient was a woman, aged 36 years, and she had had it on and off for years. There was a fair amount of evidence of dyspepsia, though not of sufficiently painful a type for the patient to volunteer any information about it.—Dr. Whitfield also demonstrated (for Dr. W. A. Milligan) a case of Paget's Disease of the Nipple in a woman, aged 51 years. There had been a discharge from the left nipple on and off since the menopause, which occurred at 45 years of age. 12 months previous to exhibition this discharge became offensive and induced her to consult a medical man. By careful dressing the scabs were removed and the discharge ceased to be offensive, though the nipple became ulcerated and the place never healed, but continued to increase in size. When shown there was an area of about the size of a five-shilling-piece over which the skin was dusky-red and infiltrated but not ulcerated. In this area there were white patches of almost normal-looking skin and this apparent improvement had taken place while the patient had been taking iodide of potassium. The nipple was not destroyed but was considerably smaller and harder than was that on the other side, while at its base there was a small hard mass to be felt which suggested a tumour rather than mastitis. There were also two large and very hard glands in the axilla. Dr. Milligan had sent the patient into the hospital for operation under the care of Mr. G. B. Mower White. Mr. White said that he proposed, in view of the presence of the glands, to remove the breast and to clear the axilla.—Mr. H. S. Elworthy showed a woman, aged 24 years, who had suffered from rumbling noises in the stomach since she was 17 years old. Her previous history showed nothing remarkable, with the exception of an attack of typhoid fever. If the patient stood up slight pressure of the left lower ribs caused a loud rumbling and gurgling noise apparently in the stomach. This was often accompanied by the regurgitation of gas up the œsophagus, and occasionally came on without any pressure. The stomach apparently hung much lower than normal, but did not reach up high under the costal margin, suggesting that a slight degree of gastroptosis was present. Mr. Elworthy considered that it was probably a gastric neurosis, but discussed the possibility of diaphragmatic hernia and dilated large intestine.—The cases were discussed by the President, Dr. J. G. Glover, Dr. A. W. Wilson, and others.—Mr. White showed a short series of Foreign Bodies found in inflamed appendices, including (1) an Appendix from an acute perforative case in which eight oxyurides were found in the organ; (2) an Appendix from a non-suppurative case in which removal had been practised as a precautionary measure to prevent a second attack and the organ was found to contain five shots and another piece of lead; and (3) a Metal Cap from the end of a pencil which was taken from a fæcal abscess in a boy, and might therefore have been either in the cæcum or in the appendix.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 7th, Dr. T. C. Meggison, the President, being in the chair.—The President showed a case of Marked Facial Paralysis.—Dr. F. S. Toogood showed (1) a typical case of Myxœdema on which he was about to commence treatment by thyroid extract; and (2) a young man who after having been knocked down by a cab was supposed to be drunk and was arrested, but was sent to the Lewisham Infirmary. Paralysis of the left side soon supervened. Dr. Toogood trephined over the posterior and anterior meningeal arteries and removed a large clot from the region of the latter. The patient made a good recovery.—Dr. James Donelan read notes of cases in which the postponement of the removal of adenoid masses in the naso-pharynx led to severe aural complications. He pointed out that the recurrence of slight earache and the evidence of Eustachian obstruction furnished by hearing tests afforded a sufficiently distinct warning to enable the practitioner to advise the immediate removal of the growth.—Dr. Morgan Dockrell and the President discussed the paper.—Dr. G. Herschell showed a new Rectal Electrode which could be distended with water while in the rectum and so afforded a larger surface for the passage of the current. He also exhibited and described a High-tension Kidder Induction-coil Apparatus which he considered to be most useful for electro-therapeutics.—Mr. R. V. Donnellan read notes of the case of a woman who had brought about abortion by thrusting a knitting-needle through the walls of the vagina and bladder into the uterus. Septicæmic symptoms ensued and her temperature was 105° F. before the birth of the child. The use of anti-streptococcic serum was followed by immediate improvement and final recovery.—Dr. Peacock (for Dr. P. Scott) read notes of an obscure case in the Miller Hospital, characterised by dulness of one lung, brawny swelling and enlargement of veins over the chest and neck, enlargement of the glands, pyrexia, and coma. The patient recovered with permanent enlargement of the episternal and epigastric veins. Various diagnoses had been suggested, including a gumma, an aneurysm, a malignant growth in the mediastinum, an embolus of the pulmonary artery, and some obscure inflammatory action. There were points against all of these.—Dr. Peacock (for Mr. J. Poland) also showed a specimen of Renal Calculi with Malignant Disease.—Mr. Augustus K. A. Cæsar showed Nine Vesical Calculi of a total weight of 4 ounces 140 grains (the largest individually weighing 7 drachms 50 grains) which had been passed by a woman, aged 70 years, who had suffered for years from complete procidentia.—Dr. J. P. Henry submitted some notes on Dionine as an Analgesic in Eye Diseases. He had tried it both in private practice and at the Italian Hospital in a number of cases of glaucoma, iritis, irido cyclitis, keratitis, and corneal ulcers, and found that while the superficial anæsthetic action was much inferior to that of cocaine it had a much more prompt and durable analgesic action on deep-seated pain in the eye which was quickly and often permanently relieved. It also favourably influenced the course of those diseases. It could be prescribed together with atropin, eserin, and pilocarpin.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on March 13th, Dr. J. Halliday Croom, the President, being in the chair.—Various members showed specimens, chiefly Myomata of the Uterus.—Mr. P. J. Freyer (as guest) showed a Myoma which he believed to be the largest intravesical tumour on record removed by a suprapubic incision; it weighed nine ounces and in labour had impeded delivery till successfully pushed out of the way.—The President, in a communication on Suppuration of the Ovary, said that such was almost invariably due to infective salpingitis and was favoured by the presence of a corpus luteum or cyst; an exceptional case upon which he had lately operated showed no intimate connexion between the tube and ovary, but a small amount of pus outside the crenated edges of a corpus luteum had led to such persistent pyrexia as was remarkable in view of the absence of fever in connexion with much larger foci in other parts of the body, notably in many cases of pyosalpinx and pyometra. The patient did well, though for 24 hours she had hæmatemesis with a quickened pulse but no pyrexia. He looked upon hæmatemesis as one of the most serious complications of abdominal work, and in his experience it had been almost always the precursor of death and so closely associated with infection that though its cause was in no way revealed by post mortem lesions he was disposed to attribute it to sepsis rather than to vomiting due to the anæsthetic, handling of the stomach and intestines, thrombosis of the omental vessels after injury or ligature and consequent embolism in the walls of the stomach, or any other cause than had been suggested. It was not confined to abdominal operations and in connexion with general surgery had been very ably discussed by Robert Purves who found it associated with a mortality of 72 per cent. Age was no factor in its occurrence.—Mr. Freyer, in a paper on Stone in the Female Bladder, drew attention to the ease and success with which litholapaxy could be performed in the female, even in very young children, or in the later months of pregnancy; the only special difficulty, escape along the side of the instrument of the indispensable fluid from the bladder, was easily prevented by the pressure of the fore and middle fingers of an assistant's hand on the posterior lip of the

France. The authors express regret that no formal course of teaching is given on the subject of deontology. They point out truly enough that the duties of the medical practitioner towards society have been shown by numerous judgments given in the law courts; that part of deontology has therefore assumed a well-recognised form and is treated of in formal lectures under the designation of "medical jurisprudence." Deontology is not, however, by any means limited to this important and well-recognised subject. It includes the duties of the medical man towards his patients, towards other members of the profession, and towards those associated with his medical work—druggists, for example, and midwives. Finally, deontology deals with "*l'ensemble des usages et des convenances professionnelles.*" The subject, it is evident, naturally covers a great deal of ground and the authors are on occasion a little inclined to be discursive; for example, the young practitioner is warned against the designing mother. The cautions given as to certain medical men who frequent health resorts may be justifiable in some cases.

At the present moment the chapter which deals with the relations between medical men and midwives is perhaps of topical interest. The authors of the book speak of these ladies as auxiliaries to the medical profession and place them a little lower than the druggists, but the positions occupied by the medical man and the midwife differ in different localities and according to the relative amount of knowledge possessed by each. Fortunately disagreements are uncommon, but they are not unknown, and examples bearing on this point are given. At the present time in France midwives have to obtain a diploma of proficiency after having studied for a period of not less than two years. The authors regard this regulation as a truly progressive one; it may diminish the number, but it will increase the efficiency, of the midwives. Ultimately, however, this will lead to a diminution in the fees received by medical men. It is therefore necessary, the authors think, that from the point of view of expediency medical students who hope ultimately to practise in the country should devote an increased amount of time and care to the study of obstetrics and ensure that their knowledge of midwifery is well in advance of that of the midwives. Medical men alone are allowed to use instruments in labours, but midwives are allowed to practise vaccination. The law runs much as follows: "Midwives are forbidden to employ instruments. In the case of difficult labours they must send for a medical practitioner. They are also forbidden to prescribe drugs," with certain exceptions. "Midwives are allowed to vaccinate and revaccinate for protection against small-pox." The authors say that, especially in the large towns, many midwives illegally practise medicine, they perform small operations, make gynæcological examinations, and treat some of the diseases of children Fines may be imposed under the Act for the illegal practice of medicine, from 100 francs to 500 francs for the first offence, from 500 francs to 1000 francs, or imprisonment for from six days to six months, or fine and imprisonment at the option of the court. The sentences actually passed, however, have been light. The experience gained in France of the effects of licensing midwives may at the present time possibly be of interest not only to medical men but also to English politicians.

---

*A Text-book of Zoology.* By G. P. MUDGE, A.R C.Sc. Lond., F.Z S London: Edwin Arnold. 1901. Pp 416. Price 7*s.* 6*d*

THIS book is designed to meet the biological requirements of the preliminary scientific examination for the M.B. Lond. and also the intermediate examination for the B Sc. Lond. The author has been most successful in writing a genuine book, but he has at the same time arranged his material [illegible]venient form for examination purposes

In the first chapter the general principles of biology are ably and clearly defined, such, for instance, as the relation of the organism to its environment, principles which it is essential that the student should thoroughly grasp at the very beginning of his studies. The second chapter gives a clear and concise account of the great classes of the animal kingdom and the differences in structure which distinguish them from one another. The following chapters deal with the animal types required by the University schedule—viz., the Rabbit, Frog, Dog-fish, Cray-fish, Earth-worm, Cockroach, Freshwater Mussel, Hydra, Amœba, and Paramœcium. The last four chapters are devoted to Embryology, Heredity, Variation, Oogenesis, and Parthenogenesis.

In the chapters devoted to the animal types the author has, in our opinion, very wisely and very successfully preferred to compare and to contrast the differences and similarities of the various organs rather than to describe each animal in detail as an entity by itself. This method not only throws into relief what is important, but it also has the immense value of preparing the student for the form in which questions are usually set at the examinations. The more important sections of the book are concisely summarised in a tabular form at the end. These tables will not only prove invaluable for purposes of revision, but they will also serve as admirable examples to the student of how to extract the essence of a matter and to cast it into a useful and accessible note. The illustrations, although they are not too numerous, are good. They are apparently for the most part sketches of actual dissections and not more or less imaginary diagrams. They will therefore serve as a faithful guide to the student in dissections and will not discourage or make him sceptical of the very existence of the parts they claim to demonstrate, as is so often the case with diagrammatic and ideal illustrations. The six coloured figures which illustrate in a general scheme the vascular organs and the course of the circulation in the principal animals considered will be especially useful to the student. It is a pity that the life-history of the cockroach is not figured, as this would have made the illustrations of the types more nearly complete, but we suppose that it is utopian to expect in English books that profusion of beautiful figures which is seen in American ones. The treatment of the important principles of heredity and variation is sound and lucid though of necessity somewhat elementary; it will, however, prove a most valuable introduction of these great doctrines to the medical student.

We can strongly recommend this book not only as the best we have seen for the purposes of the examinations for which it is intended, but as a sound and readable introduction to the study of zoology for the general reader.

*Nothnagel's Encyclopædia of Practical Medicine (Variola, Vaccination, Varicella, &c.).* By H. IMMERMANN, TH. VON JURGENSEN, C LIEBERMEISTER, H. LENHARTZ, and G. STICKER English edition Edited with additions by Sir JOHN W. MOORE, M.D. Dub. Authorised translation from the German under the supervision of ALFRED STENGEL, M.D. Philadelphia and London: W. B. Saunders and Co. 1902 Pp. 682. Price 21*s.*

THIS volume of Nothnagel's Encyclopædia of Practical Medicine contains articles on Variola, Vaccination, Varicella, Cholera, Erysipelas, Whooping-cough, and Hay Fever. These fevers have been described by their respective authors on a basis of the very widest pathology and in complete harmony with the spirit of scientific tolerance which, owing to the genius of Nothnagel, is noticeable in all volumes of the original German Encyclopædia. Broadly speaking, the general principle has been accepted with regard to each disease which is dealt with in this book that the determination of specific infections is dependent on three factors—X, Y, and Z, of which X is the specific organism, Y the external conditions necessary for the life or culture of this organism,

E. Klein, F.R.S., communicated a most exhaustive paper on Plague, illustrated by a large number of beautifully executed lantern slides.—The address was followed by a general discussion of the subject, in which Dr. R. Farrar, Dr. D. S. Davies, Mr. J. Hanclocke Wathen, and Dr. O. Symes took part.

## Reviews and Notices of Books.

*Selected Essays and Addresses by Sir James Paget.* Edited by STEPHEN PAGET, F.R.C.S. Eng. London: Longmans, Green, and Co. 1902. 8vo, pp. 445. Price 12*s.* 6*d.* net.

THE lectures, essays, and addresses contained in this volume have been selected, Mr. Stephen Paget tells us in his brief preface, as likely to prove of interest to the members of the medical profession rather than to the general reader. In saying this, however, we think that he does some injustice to the memory of his father. Several of the essays might well occupy a leisure hour of any man of letters since they treat of subjects in which all have a common interest. Amongst these may be mentioned the essay on the *Contrast of Temperance with Abstinence*, which supplies excellent arguments for the *via media* and which first appeared in the pages of the *Contemporary Review*; the essay on National Health and National Work, showing the serious diminution in the amount of work done by those who ought to be healthy and strong and free from disease as a result of preventable illness; the carefully expressed essay on the Relations between Theology and Science, in which the difficulties of the scientific and the theological mind in regard to religion are clearly put; the interesting essay on the Chronometry of Life—these and several others are characterised by such well-arranged and copious information and abundance of illustration expressed in such admirable literary form that they may be read by all with pleasure and profit. Unfortunately, the written page cannot reproduce the agreeable manner, the easy and unhesitating delivery in which the *ars celare artem* had become by long and assiduous practice perfect. At the same time, we must admit that many of the addresses possess a special value for the members of the medical profession—such, for example, as the article on Osteitis Deformans, to which Sir James Paget first called the special attention of pathologists, and those on Senile Scrofula and on Sexual Hypochondriasis. Besides the intrinsic merits of these and some other of the essays Mr. Stephen Paget has done well in selecting from his father's works those which, like the lectures on Nervous Mimicry and Dissection Wounds, can only be read by those who keep files of our own or of contemporary journals or who have access to libraries containing such periodicals as St. Bartholomew's Hospital Reports.

Sir James Paget was exceedingly happy in his choice of subjects for casual addresses, introductory lectures, and the like, though this was no doubt due to the wide views which he entertained of the relations of the medical profession to other branches of knowledge and in part to his own large information. As examples may be taken the essay entitled Errors in the Chronometry of Life, that on Stammering with other Organs than those of Speech, and that on Cases that Bone-setters Cure. The perusal of these essays impresses the reader with the high standard of literary excellence invariably maintained by Sir James Paget in his writings. Every page bears witness to the pains which he has taken to collect and to marshal his facts. He is very accurate. There is no slipslop writing nor is there any attempt at fine writing. The lectures on Nervous Mimicry are not inferior in style to the Hunterian Oration which was, perhaps, his greatest effort. That oration was delivered with great *éclat* before a crowded and distinguished audience, of whom our present King (then Prince of Wales) was one; and it is interesting, not only as one of the best amongst the many brilliant orations that have been given on that subject in the theatre of the Royal College of Surgeons of England, but because it contains the results of the reflections on Hunter's work of the man who was, after Cline, the most familiar with the contents of the museum, and who was best qualified to judge of the value of the labours of the Father of English scientific surgery.

The essay on Elemental Pathology, which constituted the presidential address to the Pathological Section at the Cambridge meeting of the British Medical Association in 1880, is an admirable example of the interest that Sir James Paget could excite upon a subject which must have long attracted his attention, though without leading him to discuss it, in his ordinary physiological and pathological lectures. In this essay he insists on the value of observations made upon the diseases of plants as illustrating the maladies of animals. He points out that hypertrophy and atrophy and senile decay are of constant occurrence in both kingdoms, and that a slow and incomplete healing of wounds takes place in plants comparable with that observed under similar conditions in animals; that parasitic growths and their consequences may be seen in both realms of nature; and that canker or cancer presents many points of analogy in plants and in animals. That he should have selected so novel a subject and have made his lecture so entertaining was a surprise to many who heard him speak on that occasion. But botany, though he modestly disclaims any more than a superficial knowledge of that subject, was by no means a strange department of knowledge to him. That address was delivered in 1880, but if we open the beautifully illustrated work of Curtis on British Entomology we shall find that in 1831 and 1832, nearly 50 years previously, he had forwarded to Mr. Curtis such excellent specimens of the plants on which the insects depicted fed, that they were selected to represent typical specimens of those plants, and it cannot be supposed that so careful and accurate an observer had overlooked even at that early period of his life many of those facts with which he illustrates his lecture.

The article on Experiments on Animals appears opportunely at the present time when the subject has been ventilated afresh in the *Times*. Whilst we have ourselves always been the consistent advocates of the prevention of all unnecessary forms of cruelty to animals we would recommend the temperate and judicial expression of opinion by Sir James Paget to the vivisection abolitionist who, led away by sentiment, exaggerates his statements till they cease to be truths and defeat their own end. We believe that Sir James Paget expresses the views of the large majority of thoughtful members of the profession in pointing out that the amount of pain inflicted by the physiologist or surgeon is trifling as compared with the huge aggregate of pain that is occasioned by the pursuit of sport or for the acquisition of adornments which has not even the plea of usefulness in mitigation. This article might well be reprinted and distributed as a circular since it is itself a sufficient answer and would serve to refute the absurd statements that, after having been categorically denied, still continue to be maintained. We have said enough, we hope, to induce many, both of those belonging to our own as well as to other professions, to purchase these—which we trust will not prove ephemeral—literary remains of Sir James Paget's work.

*Le Médecin dans la Société Contemporaine: Conférences de Déontologie.* Par MM. les Docteurs P. LE GENDRE et G. LEPAGE. Paris: Masson et Cie. 1902. Pp. 218. Price 2 francs.

To the general reader this book will prove of interest chiefly because it relates incidents in the ordinary every-day life of medical men in France, and especially in provincial

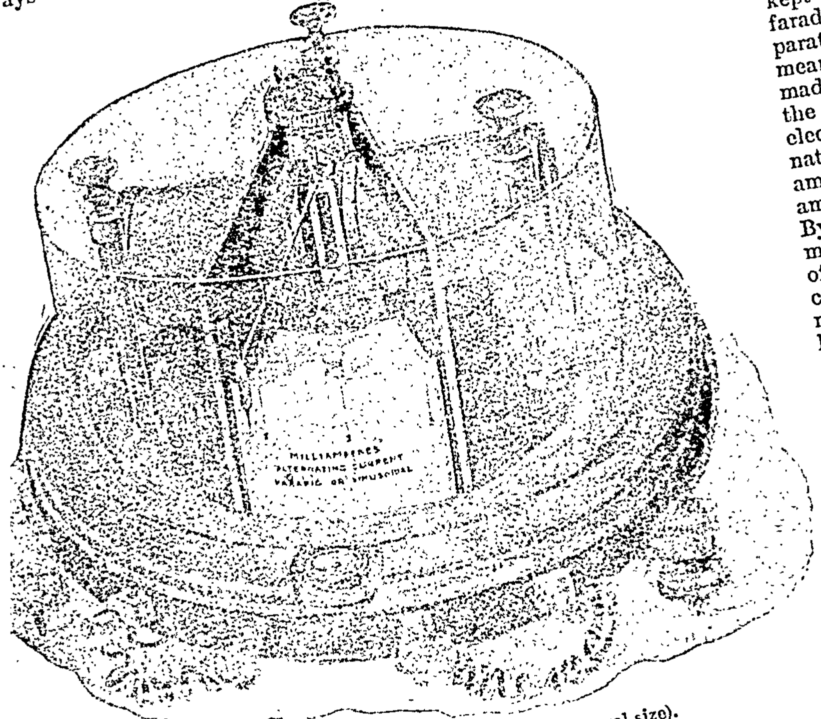
# New Inventions.

## THE FARADIMETER, AN INSTRUMENT FOR MEASURING CURRENTS FROM INDUCTION COILS FOR THERAPEUTIC USE.[1]

HAVING discovered early in my electro-therapeutic practice that no reliance—so far as continuity of action goes—could be placed on the results of treatment by means of the faradic or induced current, it occurred to me that this might be due to the impossibility of measuring the amount given, or even of knowing for certain that there was any current at all in operation. There being no instrument in the market capable of supplying this want I set myself some years go to design one. The objects aimed at in the instrument were the following. 1. That it be able to show the presence and to measure the amount of the current when this was less than a sensitive part of the body, such as the brow, could detect the presence of. 2. That it be reliable, the same current always causing the same deflection of the needle without tapping to coax the needle one way or the other. 3. That the needle always and absolutely return to the zero point. 4. That variations of temperature or draughts of air have no influence in displacing the needle from the zero point. 5. That parallax be provided against, especially in very small deflections. 6. That the instrument be dead-beat. 7. That it be independent of iron cores and of permanent magnets. 8. That the instrument be portable and not require to be placed in the magnetic meridian. 9. That the resistance be moderate to allow of a fair amount of current being possible when the intensity is low. 10. That the shunts be true for alternating and not simply for continuous currents.

Some of these objects have been more difficult to attain than others, but all the difficulties have now been overcome.

The faradimeter here described is on the principle of the electro-dynamometer but it gives direct readings. It indicates instantly any variation in the current. It is composed of two fixed coils, with a rotating coil between them, to which is attached the pointer. All the coils are as close as possible to each other. When the instrument has been leveled the suspended coil is turned so as to bring the needle to the zero point by means of the revolving stage from which it is suspended by about one inch of finest bronze ribbon. If the needle is not absolutely at zero a slight turn of one of the levelling screws will suffice to do this without putting the instrument off the level. Once set there is no need to repeat this, even when it is moved from place to place, unless some accident happen to it. In this case the revolving stage can be called into requisition again. It is fitted with the means of easily replacing the bronze ribbon and of lowering or raising the suspended coil so as to put it exactly into position. The current is carried off the suspended coil by means of a long spiral of finest bronze ribbon, the halves of this being in reverse directions to prevent displacement of the needle from zero under the influence of changes of temperature on the spiral. The instrument is made dead-beat by means of vanes of mica attached to a pointer fixed to the under part of the coil, and to prevent the action of internal currents of air through slight changes of temperature in the surrounding atmosphere these vanes are inclosed in a cell. So also is the indicating needle, since, though it is extremely fine, some slight deviation from the zero point would otherwise result from its exposure to internal currents as when placed near an open window. The rotating coil can be easily fixed an kept in this position so as to make th faradimeter portable which its comparatively small size renders easy. By means of two shunts the scale can be made to read up to 15 milliampères, the highest reading I find required for electro-therapeutic treatment by alternating currents; whilst as low an amount of current as one-fifth milliampère can be read off on the scale. By one milliampère faradic current I mean the electro-magnetic equivalent of an amount of sinusoidal alternating current, the galvanometric measurement of the sinusoidal galvanic equivalent of which is one milliampère. During calibration the earth's magnetism is controlled by a permanent magnet placed at the necessary distance above th coils. Three-milliampères sinusoida galvanic current causes, I find, th amount of deflection brought about b five milliampères from a battery. If a current of definite amount from a battery is passed through a galvanometer and then through the faradimeter and the deflection noted in each it will be found, if the current is changed into an alternating one before passing through the latter instrument, that the current in the galvanometer will fall to the medium amount, whilst the deflection in the faradimeter will remain as before, thus showing that it registers the maximum current only, the galvanometer registering the medium current only.



Faradimeter, with cover removed (half natural size).

Parallax is avoided by means of two fine strips of metal rising vertically from the pointer and about one inch apart. The total resistance of the instrument is slightly ove 800 ohms. The fixed bobbins have each 250 turns of No. 3 S.W.G. copper wire, whilst the moving coil has abou 1000 turns of No. 47 wire. The wire for the shunts is woun inductively and horizontally immediately below the bron spiral, so that the currents passing through them may affect the magnetic field around the revolving coil; and not only are the resistances proportional to the total resistance of the instrument, but the windings in the shunt coils are also proportionate in number to the total number of windings of the three coils. I have found this faradimeter of immense service and deem such an instrument absolutely essential to the proper therapeutic use of the faradic and the alternate sinusoidal currents. It has been made from my instructions by Messrs. Baird and Tatlock, Glasgow.

SAMUEL SLOAN, M.D., F.F.P.S. Glasg.,

Consulting Physician to the Glasgow Maternity Hospital and to the Samaritan Hospital for Diseases of Women, Glasgow.

[1] A paper read and an instrument shown at a meeting of the British Electro-Therapeutic Society on Feb. 14th, 1902.

and Z the susceptible subject. The mathematical conception that if any one of these three factors is wanting, or in other words equals 0, the whole product becomes zero, reconciles many of the apparently conflicting views which exponents of rival theories hold on the subject of infection. Taking, for instance, a concrete example of a miasmatic infection such as cholera, the formula X Y Z supports the views of those who, like Pettenkofer, insist on the predisposition of locality, as well as of those who, like Koch, believe in the specific character of the parasite. And by admitting the factor of susceptibility in the host the importance of diathesis is not excluded.

In the article on Variola, which is from the pen of Dr. H. Immermann of Basel, the parasitology of the small-pox virus is chiefly concerned with the investigations of Van der Loeff, Pfeiffer, and Guarnieri on the nature of a sporozoön, which is described by all these observers as possessing almost similar characteristics. The interest which attaches to the investigations of these observers centres in the fact that there is almost complete correspondence in their results. The account of the parasitology is undoubtedly of very great interest, but it is to be regretted that the editor of the English edition has not exercised his prerogative and brought the pathological history completely up to date. Dr. Immermann's vindication of vaccination in the prophylaxis of small-pox will be read with peculiar interest at the present time, since it is probably the most complete and unassailable indictment of the propaganda of anti-vaccination fanatics which has ever been published.

The articles on Cholera Asiatica and Nostras are by Dr. C. Liebermeister of Tubingen. Although in the account of the etiology of this disease controversial matter which was of more interest 40 years ago than at the present time bulks somewhat largely, nevertheless the matured experience of this veteran clinician imparts a very practical ring to everything that he has to say on the subject of symptoms, diagnosis, and treatment. As regards the latter, the value of warm and hot baths and the intravenous injection of water is fully emphasised.

The subject of Erysipelas and Erysipeloid is ably treated by Dr. Hermann Lenhartz of Hamburg. Erysipeloid, or Rosenbach's zoönotic finger erysipeloid, is a peculiar disease not generally described in English text-books, which appears to be a progressive infection which is very liable to attack the fingers of those who handle carcasses of animals, dead game, or fish.

Dr. G. Sticker supplies the chapter on Whooping-cough which is a very masterly clinical account of this spasmodic affection. The spirit of scientific tolerance which we alluded to at the commencement of this review as pervading all sections of the Encyclopædia is well exemplified in Dr. Sticker's felicitous combination of the rival hypotheses on which various authors found their definition of the disease. To quote Dr. Sticker's own words: "The majority of physicians still believe that it is necessary to decide in favour of, and to defend, one or other of these hypotheses, but few endeavour to combine them, yet nothing seems more natural than to say whooping-cough is an infectious disease as regards its external cause; it is a catarrh as regards anatomic localisation of its most marked disturbances; it is a neurosis in relation to its most prominent symptoms." The treatment of this disorder, as described by the author, amounts to little more than a destructive criticism of the methods usually employed. Quinine and camphor are practically the only two drugs which escape Dr. Sticker's sweeping condemnation.

The same author supplies a lengthy chapter on Hay Fever, under the name of "Bostock's Summer Catarrh"—a departure in nomenclature which is likely to lead to confusion, though flattering to our national vanity. In his usual brilliant and slashing style Dr. Sticker disposes of the narrow conception which many authorities entertain with regard to the etiology of this disease, and sums up the situation by declaring that "the unity of the picture described by Bostock requires a unique etiology which only the combination of a living specific excitant with a particular predisposition can satisfactorily explain."

The manner in which Sir J. W. Moore has conducted the task of translation and revision is entirely admirable, and with very few exceptions all important matter has been brought well up to date, and the discretion vested in his hands of modifying the original text where thought necessary has been most wisely exercised.

## LIBRARY TABLE.

*Reports of the Society for the Study of Disease in Children.* Vol. I. Session 1900-1901. London: J. & A. Churchill. 8vo Illustrated Pp. 238 Price 12*s.* 6*d.*—The Society for the Study of Disease in Children was founded in July, 1900. All duly qualified medical men are eligible for membership and there are already no fewer than 240 members. This first volume of reports does credit to the taste of the publishing committee and the society is to be congratulated on its satisfactory inauguration. The volume is bound in red cloth, is printed on fine glazed paper, and is supplied with excellent illustrations, among which are six beautiful chromo-lithographs of tubercle of the choroid and infantile nephritis. Every report is printed in full and is followed by a detailed record of the discussion which followed the reading of the paper. At the end of the volume there is a thoroughly serviceable index of the subjects discussed. Among the more interesting and curious reports are the following:—A case of Polyuria in a child, aged three years, by Dr. J. H. Sequeira; on Multiple Subcutaneous Fibrous Nodules in an infant apparently free from rheumatism, by Dr. G. Carpenter; on Congenital Cicatrices, by Mr. H. Betham Robinson; on a case of Myxœdema in a boy, aged six years, by Dr. Leonard Guthrie; on cases of Lupus treated by Dr. Finsen's Method; and on two cases of Cirrhosis of the Liver in Children, by Dr. C J. Macalister. The first of the two cases of cirrhosis was in a boy, aged four years, and was definitely caused by the administration of frequent doses of alcohol. This case was accompanied by much ascites and no jaundice. There were no syphilitic stigmata to be found. The parents did not deny having given to the boy frequent "nips" of spirits and beer. It seems to be generally agreed that the causes of cirrhosis of the liver in childhood are alcohol, syphilis, and the poisons of the infectious fevers. But in the second case reported there was absolutely no reason for suspecting that the child, a girl, aged 13 years, had been given alcohol at any time. "Her only previous illnesses had been chicken-pox at four and measles at six years of age. Both of these were recovered from satisfactorily and there was no indication that any of the ordinary infective fevers had started the process." There was no suspicion of syphilis in the case and the question is, What toxin could have caused the cirrhosis? This child died after an illness of rather more than a year. Post mortem there were found cell degeneration throughout the liver and intercellular as well as perilobular production of new fibrous tissue. It was a mixed type of cirrhosis Whatever the poison might have been Dr Macalister thinks that in the first place it was probably introduced with some article of food, and he quotes one or two other cases in support of his theory.

---

A PATIENT'S AVERSION TO MEDICAL MEN.—At an inquest held at Bridlington on March 10th on the body of a woman, aged 45 years, who had died suddenly, it was stated that she had persistently refused to allow a medical man to be called, stating that if a medical man attended her she would jump out of the window.

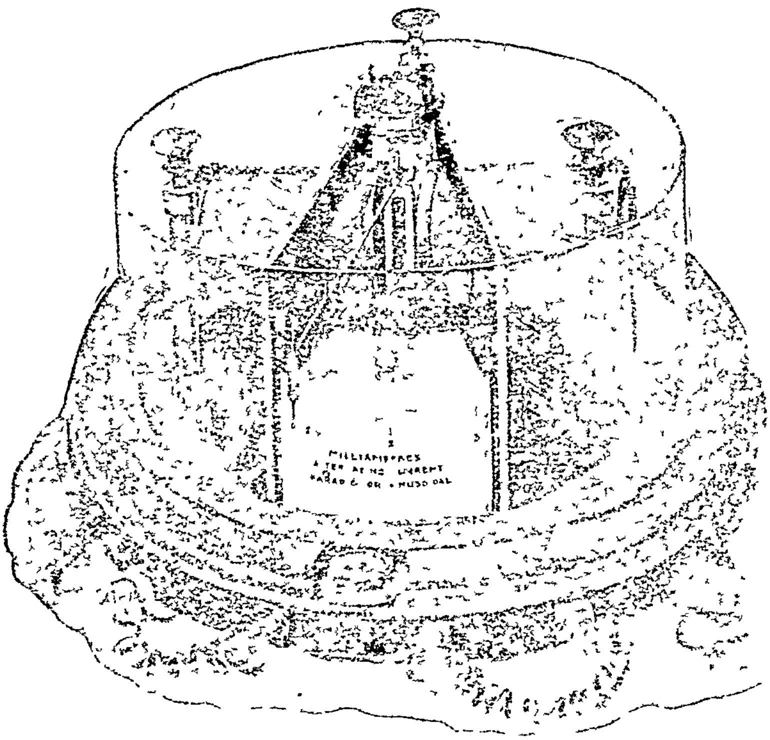
## THE FARADIMETER, AN INSTRUMENT FOR MEASURING CURRENTS FROM INDUCTION COILS FOR THERAPEUTIC USE[1]

HAVING discovered early in my electro-therapeutic practice that no reliance—so far as continuity of action goes—could be placed on the results of treatment by means of the faradic or induced current, it occurred to me that this might be due to the impossibility of measuring the amount given, or even of knowing for certain that there was any current at all in operation. There being no instrument in the market capable of supplying this want I set myself some years ago to design one. The objects aimed at in the instrument were the following. 1. That it be able to show the presence and to measure the amount of the current when this was less than a sensitive part of the body, such as the brow, could detect the presence of. 2 That it be reliable, the same current always causing the same deflection of the needle without tapping to coax the needle one way or the other 3. That the needle always and absolutely return to the zero point. 4 That variations of temperature or draughts of air have no influence in displacing the needle from the zero point 5 That parallax be provided against, especially in very small deflections. 6 That the instrument be dead-beat 7. That it be independent of iron cores and of permanent magnets. 8 That the instrument be portable and not require to be placed in the magnetic meridian 9 That the resistance be moderate to allow of a fair amount of current being possible when the intensity is low 10 That the shunts be true for alternating and not simply for continuous currents.

Some of these objects have been more difficult to attain than others, but all the difficulties have now been overcome.

The faradimeter here described is on the principle of the electro-dynamometer but it gives direct readings. It indicates instantly any variation in the current. It is composed of two fixed coils, with a rotating coil between them, to which is attached the pointer. All the coils are as close as possible to each other. When the instrument has been leveled the suspended coil is turned so as to bring the needle to the zero point by means of the revolving stage from which it is suspended by about one inch of finest bronze ribbon. If the needle is not absolutely at zero a slight turn of one of the levelling screws will suffice to do this without putting the instrument off the level. Once set there is no need to repeat this, even when it is moved from place to place, unless some accident happen to it. In this case the revolving stage can be called into requisition again. It is fitted with the means of easily replacing the bronze ribbon and of lowering or raising the suspended coil so as to put it exactly into position. The current is carried off the suspended coil by means of a long spiral of finest bronze ribbon, the halves of this being in reverse directions to prevent displacement of the needle from zero under the influence of changes of temperature on the spiral. The instrument is made dead-beat by means of vanes of mica attached to a pointer fixed to the under part of the coil, and to prevent the action of internal currents of air through slight changes of temperature in the surrounding atmosphere these vanes are inclosed in a cell. So also is the indicating needle, since, though it is extremely fine, some slight deviation from the zero point would otherwise result from its exposure to internal currents as when placed near an open window. The rotating coil can be easily fixed and kept in this position so as to make the faradimeter portable which its comparatively small size renders easy. By means of two shunts the scale can be made to read up to 15 milliampères, the highest reading I find required for electro-therapeutic treatment by alternating currents; whilst as low an amount of current as one-fifth milliampère can be read off on the scale. By one milliampère faradic current I mean the electro-magnetic equivalent of an amount of sinusoidal alternating current, the galvanometric measurement of the sinusoidal galvanic equivalent of which is one milliampère During calibration the earth's magnetism is controlled by a permanent magnet placed at the necessary distance above the coils. Three-milliampères sinusoidal galvanic current causes, I find, the amount of deflection brought about by five milliampères from a battery. If a current of definite amount from a battery is passed through a galvanometer and then through the faradimeter and the deflection noted in each it will be found, if the current is changed into an alternating one before passing through the latter instrument, that the current in the galvanometer will fall to the medium amount, whilst the deflection in the faradimeter will remain as before, thus showing that it registers the maximum current, the galvanometer registering the medium current only.



Faradimeter, with cover removed (half natural size).

Parallax is avoided by means of two fine strips of metal rising vertically from the pointer and about one inch apart. The total resistance of the instrument is slightly over 800 ohms The fixed bobbins have each 250 turns of No. 36 S W G copper wire, whilst the moving coil has about 1000 turns of No 47 wire The wire for the shunts is wound inductively and horizontally immediately below the bronze spiral, so that the currents passing through them may not affect the magnetic field around the revolving coil; and, not only are the resistances proportional to the total resistance of the instrument, but the windings in the shunt coils are also proportionate in number to the total number of windings of the three coils I have found this faradimeter of immense service and deem such an instrument absolutely essential to the proper therapeutic use of the faradic and the alternate sinusoidal currents It has been made from my instructions by Messrs. Baird and Tatlock, Glasgow

THE LANCET.

LONDON SATURDAY, MARCH 22, 1902

## The Midwives Bill

We published in The Lancet last week a full account of the proceedings in reference to the Midwives Bill before the Grand Committee on Tuesday, March 11th which terminated with an adjournment of further discussion until Friday last March 14th On that day the Grand Committee met again and completed the consideration of the measure Accordingly the Bill will be reported to the House of Commons and will probably become law as amended without further delay Accidental circumstances have combined to insure the passage of the Bill through its various stages with great rapidity, while no organised opposition was ever offered to it as a whole or even to its manifestly objectionable clauses All the combined working and all the enthusiasm have been on the side of the promoters, they have won and with them remain the spoils For there is no mincing the matter, the Bill is a distinct blow to the position of medical men Their privileges under the Medical Acts such as they are have to an appreciable extent been secured for a body of semi educated women, who will be able to embark upon obstetric practice as far as we can see without restraint enjoying much of the position of qualified medical practitioners

The amendments made in the Bill during its consideration by the Grand Committee are unimportant and affect seriously none of the drawbacks to the projected legislation An amendment proposed by Mr Parker Smith which emphasised the protection of the Bill to "midwives" by preventing uncertified persons from designating themselves "obstetric nurses" or assuming any other name properly accruing to an expert in midwifery, proved successful The amendment received no serious opposition from the promoters of the Bill and went far to show that the real purpose of the Bill has been as much to protect the title of midwife as to protect the parturient woman Mr Griffith Boscawen, Sir Walter Foster, and Mr T P O Connor tried to obtain the insertion of a clause whereby the practice of midwifery by others than women certified under the Act as midwives should be made penal, but Mr Heywood Johnstone who has served his side in the matter of this Bill with great industry and astuteness proved too many for them He objected *in toto* to the amendment which was urged on the grounds recently set out in our columns and from his point of view he was wise in doing so for we understand that the Home Office had such an objection to the proposed addition that its introduction might have imperilled the Bill By way of compromise on the question of an annual issue of certificates the promoters of the Bill have agreed to the insertion of a provision under which every certified midwife must give notice annually to the local supervising authority of intention to continue in practice within the area of the authority This is an improvement as marking some little difference in position between the medical man and the certified midwife. Sir John Batty Tuke secured an alteration in the Bill that will be of some service to the public for owing to a successful amendment proposed by him it will be impossible after Jan 1st 1905 for any woman to recover fees as a midwife in a court of law unless she is certified under the Midwives Act, but a curious position obtains under this amendment for it practically leaves persons unable to obtain remuneration legally for work which, in the absence of a penal clause has been legally executed Mr Heywood Johnstone and Mr Schwann effectively resisted a proposal to omit the invidious references in the Bill to the Royal College of Physicians of Ireland and the Obstetrical Society of London, the latter gentleman pointing out that the Obstetrical Society of London deserved recognition for its work in the matter, as its tests of candidates in the art of midwifery were more stringent than were those applied by the qualifying medical bodies to medical students Mr Schwann here took one of the numerous opportunities offered by the measure for suggesting that the certified midwife with her few months of training will be the scientific equal possibly the scientific superior, of the medical man who is compelled by the Medical Acts to submit to a curriculum of five years' duration An attempt on the part of Sir Francis Powell to substitute the General Medical Council for the Privy Council as the body responsible for the formation of the Central Midwives Board failed, Mr Heywood Johnstone thinking that the Lord President of the Council would be able to discharge the duty put upon him which consisted only of having a few letters written We are not so confident Words have been inserted to secure that before the Privy Council approves of any rules framed by the Central Midwives Board the General Medical Council shall be consulted but precedent does not lead us to believe that much consideration will be extended to the medical view

Presumably the end of a long struggle has been reached, for we do not see now what remains to prevent the latest edition of the Midwives Bill from becoming law We do not think that the members of the medical profession as a whole can congratulate themselves much in the matter A large proportion of the profession were in ignorance of the pros and cons of the question until it became acute That many of them when they awoke to a sense of the importance of the issues of a Midwives Bill were opposed to the measure is true but opposition that would have been effective in the earlier stages proved abortive when offered in belated and fitful manner Again those members of the medical profession who were from the first interested in the certification or registration of midwives were sharply ranged into opposing camps One party saw in the legislation for the regulation of the practice of midwives the creation of an inferior body of general practitioners to the defiance of the Medical Acts and the obvious danger of the parturient poor, the other party saw in the same legislative proposals a guarantee that the parturient poor would in all circumstances be able to obtain trustworthy and cleanly ministrations Of course each side was somewhat wrong but neither would attempt to find a middle way. Neither would abate a jot from the position that it had taken up, with the result that the public and the Government have shown themselves unable to attach importance to medical opinion. The General Medical Council has suffered in prestige, for, although it was generally considered to be more or less of an undertaking that no Midwives Bill would receive the support of the Privy Council unless it was framed upon lines approved by the General Medical Council, the measure that now approaches the statute-book does not contain the desiderata of the General Medical Council, and, so far as we know, has the general approval of the Privy Council. The Direct Representatives of the profession on the General Medical Council will have to explain the position to their constituents as best they can. If they cannot redeem their election pledges it is unlikely that their disability will remain concealed.

# Our Medical Duty towards our Neighbour.

From time to time the immediate presence of epidemic disease arouses in the general public the fear of infection and to some extent teaches the desirability of sanitary precautions The same occasions of temporary alarm, however, reveal the apparently ineradicable recklessness of a large section of the public where others only are concerned and the inadequacy of any laws to safeguard the public health as long as men and women have no desire to do their duty towards their neighbours apart from legal compulsion. The difficulty of successfully isolating suspected cases of small-pox is no doubt in many instances due to the fact that the suspected person is a worker whose presence among his fellow workers is necessary if he is to earn his wage. In such circumstances it is not surprising that the maxim of "every man for himself" is often observed with disastrous consequences ; but the qualified kind of necessity that prevails in these cases is not to be found by any means in all the instances where persons have deliberately exposed others to the infection of small-pox during the present epidemic. We have narrated examples where criminal carelessness has led to the chances of spreading small-pox during the recent epidemic, and our readers know that small-pox is not the only or the most frequent pathological condition so disseminated. The publicity recently given to the result of scientific inquiry with regard to the spreading of the infection of tuberculous disease has called some attention to the filthy habit of expectorating in public conveyances, in the streets, and in other places of public resort Newspapers and other popular publications have devoted a good deal of space to discussing the matter, and every opportunity has been given, even to persons of the class that spits, of knowing that the sputa of tuberculous persons may become a source of infection to others, but we doubt if the dissemination of such information has to any substantial extent diminished what is a disgusting act and a public nuisance, quite apart from the risk of spreading disease The agitation may have produced notices requesting persons not to expectorate in places where such notices can to some extent be enforced, but the fact that such notices are needed at all shows how absolutely selfish certain members of the community are and how neglectful they are of the simple rule of doing as they would be done by. We will pay the persons who spit on the floors of omnibuses and other public vehicles the compliment of believing that they do not do so on the floors of their own homes, but we will ask them what their feelings would be if other persons came and squirted saliva over their boards or carpets as they do over the boards and carpets of the railway companies ; and here we may point out that the persons who spit in railway-carriages are not confined to the class whose homes are destitute of carpets.

In preventing the spread of infectious disease the community is to some extent aided by the law that compels the notification of certain disorders and imposes penalties upon persons suffering from them who expose others to the risk of infection in certain obvious ways. A large number of persons, however, regard the precautions imposed by law as embodying the maximum of care that they need show for others ; and the attitude of many parents in the humbler classes of society whose children have suffered from such diseases as scarlet fever and measles is one of indifference as to whether their neighbours suffer in a similar way or not. They reason that as they have had the trouble and inconvenience of having their own children laid up, it will only be an equal distribution of the ills of life if those around them undergo the same affliction. Any obligation on themselves to go out of their way to prevent, if possible, such a thing from happening, because it is their duty to think of, and to protect, others, they ignore or openly deny. The kind of duty of which we are speaking—which we may call our medical duty towards our neighbours—is still more often disregarded by members of all classes when there is no question of existing disease that may be disseminated. The persons who in the disposal of house refuse only consider how they may in the easiest way get rid of it without detection and interference on the part of some sanitary authority possibly regard the law, but they very often neglect their duty. Every piece of waste land in or near a town testifies to this neglect, just as every reach of the Thames above London bears similar evidence in spite of the vigilance of the river commissioners, and in spite of the obvious wickedness of fouling a noble river. In the preparation of food-stuffs a similar course of conduct shows itself and is from time to time demonstrated in our police-courts, whether the question is one of adulteration merely or of the sale of food positively dangerous to health. Very often it is shown that there has been no deliberate intention of making money out of a commodity known to be unfit for human food. The most frequent plea for a mitigated penalty is the one that rests *on the allegation that* the defendant *never saw the* stuff that he offered for sale and knew nothing about it Carelessness and selfishness lead to an obvious neglect of medical duty.

It would not be difficult to give many more examples al bearing upon the same point and showing how often men and women place others in danger without compunction, whereas they themselves, if they suffered from similar conduct, would be loud in their complaints of their neighbours So far as the law goes it protects us from our neighbours and its sphere of authority is constantly being extended ; but those whose duty it is to enforce the law cannot be present everywhere or omniscient These are days of extended and extensive education, and it is much to be wished that the teachers of the young should at all convenient seasons, whether in the course of religious or of lay instruction, instil into their minds the duty of protecting others even to their own inconvenience. With the inculcation of a sense of such duty increased knowledge of the sources of disease and the possibilities of sanitary science would be of more avail. At the present time, through the ignorance of some and the callousness of others, disease is spread in all populous centres in a terrible, because in an entirely unnecessary, manner. We cannot help thinking that the board schools might well come to the rescue of the community with a little plain talk to their charges.

◆

## Varicose Veins.

THE Lettsomian Lectures of the Medical Society of London were established in 1850 They are always intrusted to some distinguished Fellow, and this year the lecturer was Mr. A. PEARCE GOULD. It is generally understood that the subjects of these lectures are intended to be as practical as possible, and Mr. PEARCE GOULD'S choice of the subject of varicose veins for his first lecture (which was published in THE LANCET of March 1st, p. 576) was very happy. It is a disease which is exceedingly common, obscure in its origin, and but little amenable to the many methods of treatment adopted. Many who suffer from varix are in good, even in robust, health. This fact is against the condition being a degeneration Much importance in the production of varix is usually attributed to obstruction to the return of venous blood as by pressure on the larger veins. Mr. PEARCE GOULD does not assert that pressure has no effect, but he believes that it is unworthy of being considered in comparison with other factors. He showed that in the vast majority of cases varicose veins first appear before growth is complete; thus out of 50 consecutive cases of varicose veins coming under his observation the condition was manifest before the age of 25 years in 41, that is to say, in at least 80 per cent of cases the varix appeared before development was complete. Now, as it is certain that venous obstruction does not predominate during adolescence, hindrance to the venous circulation cannot, he argues, be an important factor in the production of varicose veins Another argument on which the lecturer rightly laid stress is the conspicuous absence in this disease of all the usual signs, symptoms, and consequences of venous obstruction Œdema, lividity, and impairment of function are rarely seen in varix, while in cases in which undoubted venous obstruction is present—as, for instance, when a bandage has been applied too tightly—discomfort immediately follows, the whole limb becomes obviously congested, and œdema rapidly supervenes. Further, the operative treatment that is usually adopted for varicose veins—namely, ligature or excision—is itself a potent argument against the obstruction theory, for, if obstruction is the cause, to excise the varix or to ligature the main cutaneous vein above must be an utterly irrational procedure, yet all surgeons will acknowledge the value of both of these measures.

Of all the suggested causes of venous obstruction leading to varix pregnancy holds the most conspicuous place, but Mr. PEARCE GOULD pointed out that in most cases careful inquiry will elicit the fact that the enlarged veins had been noticed in early life before marriage, but that the patients had never been troubled by them until pregnancy occurred. The important vaso-motor disturbances which are produced in some women by pregnancy show how greatly the vascular system can be affected by this condition. Therefore we need feel no surprise that the veins should suffer also, quite apart from any pressure on them. Large tumours of the ovary and uterus probably cause quite as much pressure on the iliac veins as does a pregnant uterus, yet they are much less frequently attended with troublesome varix of the lower limbs There is, however, a still more forcible argument against the pressure theory, and this is to be found in the relative proportions in which the sexes are affected with varicose veins We find that, according to Mr. PEARCE GOULD'S figures, of 245 cases, made up of cases seen in private and cases seen during the last six years in hospital practice (cases of varicocele being excluded), 153 were men and only 92 were women. Of course, if the cases of varicocele had been added the excess of male patients over female would have been greatly increased. The rôle, therefore, of pregnancy in the production of varix must be unimportant. If, however, we are compelled by facts to throw over the obstruction theory of the etiology of varix, what can be put in its place? Mr PEARCE GOULD answers that varicose veins are venous overgrowths—that is to say, venous angeiomata. He brings forward cases which demonstrate that even in the latter half of life veins may form, constituting what may be called a "venous angeioma," while in evidence that varix is really a variety of angeioma he quotes many proofs. In the first place we occasionally meet with combinations of undoubted venous nævus and varix; and there are other cases in which we might hesitate as to which term should be employed, or in which, indeed, either might be used with perfect propriety Secondly, the irregular distribution of varicose veins is much in favour of the view that we are dealing with an over-development of the venous tissue. A further proof is to be found in the distinctly hereditary character of varix, which may, indeed, in some cases be traced through three generations Moreover, in the majority of cases an extreme degree of varix persisting for many years is quite compatible with unimpaired function and structure of the parts from which the varicose veins receive their blood. Mr PEARCE GOULD considers that the minute structure of a varicose vein, containing as it does an increase of muscular tissue, is in favour of the developmental theory—the theory, that is, that varices are essentially the result of an over-development of venous tissue We must acknowledge that these arguments are of great weight and go far towards establishing the lecturer's contention.

The latter half of the lecture dealt with the question of treatment In 1891 TRENDELENBURG of Bonn introduced a novel method of treating varicose veins by ligature of the great saphena vein in the upper part of the thigh He showed that the enlarged veins filled from the proximate end and that pressure over the great saphena prevented the blood from entering them The operation has been widely practised, but opinions are divided as to its value. Mr. PEARCE GOULD published in 1899 the results of his first 50 cases after

**TRENDELENBURG'S** operation, and at the lecture he presented a table showing the present condition of the patients in all the cases operated on since, so far as they had been seen or reported on. These were 50 in number, and they showed clearly the beneficial effect of the operation in most cases. Except in two instances all the patients expressed themselves as being in less pain than before the operation; in no case had any increase of the varix occurred, and the tendency to thrombosis was greatly lessened. The lecturer summed up his remarks on treatment by saying that in **TRENDELENBURG'S** operation we have a simple and safe proceeding and one very useful in nearly all cases of varix. In conclusion we may add that the lecture was an excellent illustration of the light which may be thrown on a subject generally supposed to be fully understood by a careful consideration of facts and logical deductions from them.

# Annotations.

"Ne quid nimis."

## THE NATIONAL PHYSICAL LABORATORY.

RATHER more than 30 years ago the suggestion was made by Lord Kelvin that the nation should possess a physical laboratory in which standards could be preserved and the work of standardisation carried on. The opening of the National Physical Laboratory at Teddington by the Prince of Wales on Wednesday, March 19th, marks the consummation of this valuable suggestion, although the equipment of some departments is not yet complete for want of funds. The work which this institution will undertake is of the most important kind. It will relate chiefly to the standardisation and verification of instruments and the determination of physical constants. Ample scope for the investigation of certain industrial problems in which the application of scientific study and research is indicated will be afforded as the income of the institution will allow. The Government has granted £14,000 for fitting up Bushy House (an old Royal residence) for the purpose and a maintenance of £4000 a year. It is believed that the house is remote from external physical disturbances, special attention having been given to isolating the building for the purpose of conducting electrical and magnetic measurements. It is to be hoped that the lack of funds owing to which the equipments in some respects are deficient will soon be made up and that the nation will by its practical help realise the importance of such an institution being maintained in an efficient state

## THE METROPOLITAN WATER-SUPPLY.

THE report of the Water Examiner on the condition of the metropolitan water-supply during the month of January last has at length been published The Thames water at Hampton, Molesey, and Sunbury was "more or less coloured" from the first to the seventh day of the month and was described as of "indifferent" quality during that period by the engineer to the Chelsea Company. The height of the river varied between a point one foot above and one seven inches below the average summer level The daily average amount of water distributed by the eight companies was 198,233,165 gallons for a population estimated at 6,314,223, which represents a daily consumption per head of 31 39 gallons. The companies which deliver less than this amount daily per individual are the Kent, the New River, and the East London; the others deliver more. During the month of January, 1902, the New River and the Lambeth companies distributed a larger quantity of water per head to their customers than they did in the corresponding month of the year 1901; each of the other companies delivered less per head than during the earlier period. The Lambeth Company's water on Jan. 1st, 3rd, 6th, and 8th was slightly opalescent. The water of the Lambeth Company also exhibited "the deepest average tint of brown." Dr. T. E Thorpe, F.R S., the analyst to the Local Government Board, reports that he made a full analysis of one specimen each of water derived from the mains of each company. The samples were taken on Jan. 20th—a date on which the Thames water was not in a "bad" or "indifferent" condition. The proportional amount of organic impurity found in the samples examined is numerically represented as follows:—Kent Company 1·1, New River 1·4, Lambeth 3 4, Southwark 3 6, Grand Junction 4·3, West Middlesex 4·5, East London 5 0, and Chelsea 5·3. There is one paragraph of the Water Examiner's report which as it stands is incomprehensible or incomplete. It is as follows (p. 5): "The river intake of the filters of the Southwark and Vauxhall Company at Hampton was closed from the 1st to the 8th of the month inclusive"—that is readily understood: the engineer to the Southwark Company preferred not to introduce flood water directly to the filter-beds The paragraph continues, "And the intake of the Lambeth Company was also closed from the 6th to the 18th inclusive." If this be so the intake was closed for 13 days. The reservoir storage capacity possessed by the Lambeth Company is stated on the next page (p. 4) to be sufficient only to contain a supply for 4·6 days—indeed, not sufficient for that time, because (p. 4) "for several reasons the reservoirs cannot be drawn down to the limit of their capacity, and the available storage may be taken at about 15 per cent. less than that above stated." For over a year this little explanation has appeared monthly—perhaps it is not too much to hope that some day the Water Examiner may give as accurately as possible the available capacity of the reservoirs of each of the metropolitan water companies. The question which more immediately excites our curiosity is, Where and by what means did the Lambeth Company obtain water from the 6th to the 18th of January last (both days inclusive)?

## UNAVOIDABLE ERROR.

THE following story, which we quote from the *Times* of March 10th, was told at the Thames Police-court. It is quite probable that upon investigation it may have been found inaccurate in its details, but it suggests some of the hardships that arise almost unavoidably when dangerous infectious disorders break out among the poor. A man had been living at some model dwellings at Bow and some time ago was suffering from a cold, but by some means it got about that he was suffering from small-pox. By order of the local authorities he was removed to the small-pox hospital and after being detained there for some days he was allowed to go as there was nothing the matter with him. On returning to his rooms he found that all his things had been removed and destroyed and he now wanted to know who was responsible for the loss which he had sustained. The magistrate is reported as saying that he was unable to answer the question, but that he advised the applicant to see the local authorities. Probably Mr. Dickinson felt that, as we have suggested, the facts of the case were not fully before him. The Public Health and Infectious Diseases (Notification) Acts contain provisions designed with a view to protect the public at large when individuals are found to be suffering from dangerous infectious disorders, but certainly without any desire to inflict unnecessary hardship on the sick and extensive education, and it is much to be wished that the teachers of the young should at all convenient seasons, whether in the course of religious or of lay instruction, instil into their minds the duty of protecting others even to their own inconvenience. With the inculcation of a sense of such duty increased knowledge of the sources of disease and the possibilities of sanitary science would be of more avail. At the present time, through the ignorance of some and the callousness of others, disease is spread in all populous centres in a terrible, because in an entirely unnecessary, manner. We cannot help thinking that the board schools might well come to the rescue of the community with a little plain talk to their charges.

## Varicose Veins.

THE Lettsomian Lectures of the Medical Society of London were established in 1850. They are always intrusted to some distinguished Fellow, and this year the lecturer was Mr. A. PEARCE GOULD. It is generally understood that the subjects of these lectures are intended to be as practical as possible, and Mr. PEARCE GOULD'S choice of the subject of varicose veins for his first lecture (which was published in THE LANCET of March 1st, p. 576) was very happy. It is a disease which is exceedingly common, obscure in its origin, and but little amenable to the many methods of treatment adopted. Many who suffer from varix are in good, even in robust, health. This fact is against the condition being a degeneration. Much importance in the production of varix is usually attributed to obstruction to the return of venous blood as by pressure on the larger veins. Mr. PEARCE GOULD does not assert that pressure has no effect, but he believes that it is unworthy of being considered in comparison with other factors. He showed that in the vast majority of cases varicose veins first appear before growth is complete; thus out of 50 consecutive cases of varicose veins coming under his observation the condition was manifest before the age of 25 years in 41, that is to say, in at least 80 per cent. of cases the varix appeared before development was complete. Now, as it is certain that venous obstruction does not predominate during adolescence, hindrance to the venous circulation cannot, he argues, be an important factor in the production of varicose veins. Another argument on which the lecturer rightly laid stress is the conspicuous absence in this disease of all the usual signs, symptoms, and consequences of venous obstruction. Œdema, lividity, and impairment of function are rarely seen in varix, while in cases in which undoubted venous obstruction is present—as, for instance, when a bandage has been applied too tightly—discomfort immediately follows, the whole limb becomes obviously congested, and œdema rapidly supervenes. Further, the operative treatment that is usually adopted for varicose veins—namely, ligature or excision—is itself a potent argument against the obstruction theory, for, if obstruction is the cause, to excise the varix or to ligature the main cutaneous vein above must be an utterly irrational procedure, yet all surgeons will acknowledge the value of both of these measures.

Of all the suggested causes of venous obstruction leading to varix pregnancy holds the most conspicuous place, but Mr. PEARCE GOULD pointed out that in most cases careful inquiry will elicit the fact that the enlarged veins had been noticed in early life before marriage, but that the patients had never been troubled by them until pregnancy occurred. The important vaso motor disturbances which are produced in some women by pregnancy show how greatly the vascular system can be affected by this condition. Therefore we need feel no surprise that the veins should suffer also, quite apart from any pressure on them. Large tumours of the ovary and uterus probably cause quite as much pressure on the iliac veins as does a pregnant uterus, yet they are much less frequently attended with troublesome varix of the lower limbs. There is, however, a still more forcible argument against the pressure theory, and this is to be found in the relative proportions in which the sexes are affected with varicose veins. We find that, according to Mr. PEARCE GOULD'S figures, of 245 cases, made up of cases seen in private and cases seen during the last six years in hospital practice (cases of varicocele being excluded), 153 were men and only 92 were women. Of course, if the cases of varicocele had been added the excess of male patients over female would have been greatly increased. The rôle, therefore, of pregnancy in the production of varix must be unimportant. If, however, we are compelled by facts to throw over the obstruction theory of the etiology of varix, what can be put in its place? Mr PEARCE GOULD answers that varicose veins are venous overgrowths—that is to say, venous angeiomata. He brings forward cases which demonstrate that even in the latter half of life veins may form, constituting what may be called a "venous angeioma," while in evidence that varix is really a variety of angeioma he quotes many proofs. In the first place we occasionally meet with combinations of undoubted venous nævus and varix; and there are other cases in which we might hesitate as to which term should be employed, or in which, indeed, either might be used with perfect propriety. Secondly, the irregular distribution of varicose veins is much in favour of the view that we are dealing with an over-development of the venous tissue. A further proof is to be found in the distinctly hereditary character of varix, which may, indeed, in some cases be traced through three generations. Moreover, in the majority of cases an extreme degree of varix persisting for many years is quite compatible with unimpaired function and structure of the parts from which the varicose veins receive their blood. Mr PEARCE GOULD considers that the minute structure of a varicose vein, containing as it does an increase of muscular tissue, is in favour of the developmental theory—the theory, that is, that varices are essentially the result of an over-development of venous tissue. We must acknowledge that these arguments are of great weight and go far towards establishing the lecturer's contention.

The latter half of the lecture dealt with the question of treatment. In 1891 TRENDELENBURG of Bonn introduced a novel method of treating varicose veins by ligature of the great saphena vein in the upper part of the thigh. He showed that the enlarged veins filled from the proximate end and that pressure over the great saphena prevented the blood from entering them. The operation has been widely practised, but opinions are divided as to its value. Mr. PEARCE GOULD published in 1899 the results of his first 50 cases after of Physicians and a Doctor of Medicine of Cambridge University, that "no man brought more mind to his profession," and it is a question whether the man thus appraised really lost caste, as his biographers aver, by first patenting and then advertising a drug. Certain it is that he was struck off no books, and Dr. Johnson, that model of scrupulous honour, was his friend to the last. Was he even censured for making a false specification in his patent? And what was the state of professional feeling which permitted a Doctor of Medicine to publish a "Vindication" of his powders? In the seventeenth century advertisements setting forth the merits of medical graduates and other apparently reputable persons were common in the journals. In the *True Domestick Intelligence* for March, 1680, we find Thomas Kyrle issuing an extraordinary manifesto which begins, "The old and true way of practising Physick revived and published for the publick good." The puff, which is very long, describes his system of charging fees only in case of cure, his readiness to treat the poor for "thanks" only, and so on. The price of his doses is given and his address, "the first balcony" in a certain city lane. And this man, Thomas Kyrle, or Kirleus, was no quack, but Charles II.'s "sworn phisitian in ordinary," and he issued his statement, as he avers, under the seal of the College of Physicians and with their approval. In the "twenties" and "thirties" of the century just passed these medical declarations to the public seem to have been still quite in vogue. An old newspaper cutting now lying before us "respectfully informs the public" that a Member of the Royal College of Surgeons in London "has had more than 30 years' practice in midwifery, and has paid particular attention to the operative department of surgery," including the successful treatment of hare-lip and ulcers in the legs. On the other hand, it is noticeable that several satirists in the eighteenth century and earlier make no mention of printed advertisements. In his brilliant "Dose for the Doctors" (1789) "Gregory Glyster, an Old Practitioner," most maliciously and wittily suggests a dozen ways in which a medical man may puff himself without seeming to do so, but print is not one of them, though ornamental door-plates and exaggerated medical degrees are duly recommended. Again, writing in 1651, Robert Record reprints in a slightly modernised form "A Detection of Unskilfull Physitians," which is reported to be the work of a Salisbury doctor in Queen Elizabeth's reign. And here again printed puffery is not hinted at, although the country is said to be infested by a "sort of fellows, which nowadays almost in all places so rashly, so fondly, and so wickedly do abuse the noble Art and Science of Physick."

## WOOLWICH AND THE HOUSING OF THE WORKING-CLASSES.

DR. SIDNEY DAVIES, the medical officer of health of the borough of Woolwich, has issued a "Further Report to Housing of Working-Classes Committee on Overcrowding and the Population requiring Re-housing in the Borough of Woolwich." The facts disclosed by this report are by no means creditable to the civilisation of the twentieth century. Houses are difficult to obtain in the district under Dr. Davies's charge for two reasons. First, there is a definite lack of houses, and, secondly, people with large families are very often refused as tenants, even though they can pay the high rents demanded. This lack of houses reacts unfavourably on sanitation because, says Dr. Davies, "Landlords who only look to their rents are careless as to the complaints of tenants as to defects in a house, knowing that however bad its condition it is sure to be reoccupied as soon as it is empty. The health authority and its officers hesitate to take steps for closing a house which is sanitarily unfit for occupation, knowing that the displaced tenants may be unable to find adequate accommodation elsewhere. 'A bad house,' it is sometimes said, 'is better than no house at all.'" It may be said that there is a certain class of tenants who are most destructive and who think nothing of tearing down sanitary fittings for the purpose of selling them as old metal. The damage done by such is, however, in no way comparable to that done by the bad landlord. He it is to whom are due the horrible overcrowding, the one-roomed tenements and the immorality and vice which are the inevitable accompaniments of such overcrowding. For a four-roomed house he will draw over £30 per annum in rent and a court or street of such houses will be a veritable focus of disease affecting the neighbourhood far and wide. When matters get to such a pitch that after great difficulties his property is ordered to be destroyed he is bought out at a high rate and goes away to buy or to build further fever dens.

## VACCINATION DIFFICULTIES.

IN THE LANCET of March 15th, p. 761, we commented upon sundry matters concerning vaccination and public vaccinators at Helston. The town council had issued bills pointing out the advantages of vaccination and revaccination and intimating that anybody who wanted to be vaccinated could be vaccinated by the public vaccinator, whose name was given. It is obvious, as we noted, that in a case such as this every care would have to be taken that the public vaccinator did not attract other practitioner's patients. In this instance, however, the public vaccinator had nothing to do with the issue of the circular. A correspondent has forwarded for our inspection a circular signed by a practitioner who is medical officer of health of a certain urban district council. The circular points out the advantages of vaccination and revaccination. Our correspondent, though, writes to us that he considers the issue of the circular very unfair to himself and to other men in the district, for the medical officer of health in question is in private practice. We think it would have been better if it had been made plain that the circular in question had been issued by the urban district council, for though it apparently only emanates from the medical man, yet we can hardly suppose that he, not being a medical officer of health who is not allowed private practice, would send out such a circular on his own initiative. Possibly the difficulty might be got over by making every medical man a public vaccinator, and this course has been recently urged by the adoption of the following resolution by a meeting of the council of the Lancashire and Cheshire branch of the British Medical Association:—

> That in the opinion of this council, seeing that vaccination is made compulsory, in the interests of the public health, the parent or guardian of a child should have the right to select any registered medical practitioner, who is willing to do so, to perform the vaccination, and that the cost of the same should be defrayed by the State at a fixed rate, provided always that the work so done shall reach the standard aimed at by the Local Government Board in the case of public vaccinators, and that no work falling short of this standard should be accepted for the purpose of public remuneration.

The matter is one which presents many difficulties. Vaccination and revaccination should be indefatigably preached. It is the duty of all health authorities, of individual medical men, and of the clergy to impress people with the value of the practice; but individual medical men must be careful to avoid any appearance of wishing to draw away the patients of their brother practitioners. With regard to the position at Helston, at the meeting of the Helston Board of Guardians held on March 15th it was decided to ask all the public vaccinators to continue to act on their old contracts. The guardians at first wished the public vaccinators to provide all extra calf-lymph at their own expense, but these gentlemen declined to accept these terms and consequently the guardians decided to pay for all such extra lymph. The clerk was instructed to write to all the public vaccinators rescinding the notice to determine persons. The local authority may direct the destruction of bedding, clothing, or other articles which have been exposed to infection from any dangerous infectious disorder, but it is also empowered to give compensation for the destruction so wrought. We do not believe that such compensation would or could be refused because it was discovered that the destruction was not required owing to there having been in point of fact no exposure to infection. With regard to any distress or inconvenience entailed upon the individual wrongly suspected and removed, but not in fact suffering from a dangerous infectious disorder, some distress and inconvenience must necessarily, we fear, be borne at times by individuals if the public is to be protected. Those locally responsible for the public health have certain powers given to them which enable them to take charge of persons suffering from specified disorders who are without proper lodging and accommodation. In such cases action is only taken on the certificate of a legally qualified medical practitioner, and, apart from any negligence, it is not easy to see any legal grounds upon which compensation might be claimed from the sanitary authority as such. On the other hand, members and officials of local authorities and persons acting under the directions of local authorities are protected from personal liability for acts done by them *bonâ fide* for the purpose of executing their duties under the law, and, apart from negligence, we do not understand how the person in whose case a mistake has been made can have any claim against individuals. Still, such cases as that to which we have referred are hard cases when they occur, and it is dispensing cold comfort to hint to the man who has been taken from his home unnecessarily that he owes it to vaccination that he has been in a small-pox hospital without contracting small-pox. That mistakes in the diagnosis of small-pox must inevitably occur needs no demonstration, but we may call attention to an answer given by Mr. Long to a question in the House of Commons on March 10th. The right honourable gentleman stated that in Bethnal Green in January and February 136 cases were reported, which presumably means certified, as small-pox, and that in 13 *cases it was found that mistakes had been made.* This, however, does not imply that the cases so reported were dealt with as small-pox cases before the error was discovered, nor does it mean that there was any negligence or default of any kind on the part of those by whom, or through whom, the reports were made. Such mistakes, moreover, however much they are to be regretted, are, to use a popular expression, "mistakes on the right side," and are not so dangerous *to the community at large as* are *those* which leave persons who are suffering from small-pox to be sources of infection to all around them.

## LIGHT AND MALARIA.

THE demonstration of the plasmodium as the *vera causa* of malarial fevers and the successive sporulations of the parasite as the exciting causes of the paroxysms have exploded many popular and traditional beliefs and have explained those that experience has established as to the conditions under which these diseases prevail and the means by which they may be prevented, as being simply such as are most favourable to the multiplication of the anopheles and such as tend to its extermination. But there are still some facts hitherto unexplained pointing to conditions connected with solar phenomena, *and not unnaturally ascribed to the sun's* heat as the most obvious and palpable of these. But it is not easy to imagine how the parasite can be influenced by external temperatures, since it is itself in a medium, the blood, which is not affected thereby, the pyrexia of the paroxysm being the effect, not the cause, of its intermittent activity. In the *American Journal of the Medical Sciences* for February Dr. A. F. A. King of New York puts forward an ingenious suggestion that the actual factor in question is the light, not the heat, of the sun, and that the relative immunity of the very dark and black races of man is due to the lesser translucency of their skins. Celli and Tacchini had noticed that the years in which the fevers were most severe in Italy were by no means the hottest, though the number of cloudless days was above the *average. Jackson remarked* that in Jamaica a camp over which a fog hung all day suffered less than did those apparently better situated, and the beneficial effects of several days of heavy rain have often been noticed. Flint states that paroxysms very rarely occur at night and that, recurring some hours later each successive day, when they fall after dark they are usually deferred to the following morning, when they may sometimes be avoided by the patient lying in bed through the day. The experiments of Harrington and Leaming on the common amœba lend considerable support to this hypothesis, for they found that the amœbæ "streamed" under the influence of bright sunshine, but still more actively when exposed to red light, whereas the process was arrested in the darkness and was completely inhibited by the violet and ultra-violet rays. Since the skin of all but the blackest races, and especially that of white men, is more or less translucent, it is evident that blood parasites may be susceptible to the influence of the light of the sun, though protected by the constant heat of the body from that of external temperature, and that it is chiefly the red rays that can reach them through the medium of the blood. Until it shall have been proved that the blood of the negro is darker than is that of the white man, and that the colour of the latter can be perceptibly altered by practicable dosage with methyl blue or can be made fluorescent by the administration of quinine, we must forbear following Dr. King in his speculations on these points, but we think that he has made out a fair case for his light theory and for the trial of what may be called "scoto-therapy" in the treatment of malarial fevers—that is, of keeping the patient in a dark room and *in the intervals between the attacks* of clothing him in garments with linings impenetrable by *light*

## OLD MEDICAL PUFFS.

THE recent controversy on the impropriety of advertising the name of a medical man without his knowledge raises again the whole question of medical advertisements. In certain of its aspects, at least, medical etiquette is undoubtedly in process of growth even now, and in the absence of definite evidence wonder may be expressed whether, as a whole, it has arisen, like the Common Law, from humble Anglo-Saxon beginnings, or whether, like a creed, its essentials come to us stereotyped out of Latin and Hellenic antiquity. Supposing the medical code of honour to be, so to speak, progressive, then it follows that there was a time when medical ethics permitted puffery. Certain it is that old newspapers abound in medical puffs which in many cases emanate from seemingly respectable sources. The question is, How were these puffs viewed by the medical men of the day? *Were they considered venial or disgraceful?* Dr. James's "Fever Powders" were regularly vaunted in print, as poor Dr. Goldsmith found to his cost when he insisted on taking them contrary to his apothecary's advice. Oliver Goldsmith died from fever, and James's powders were especially recommended as "a most effectual Remedy for all internal Inflammations, Pleurisies, Quincies, acute Rheumatisms, and the *Lowness of Spirits, and Uneasinesses* proceeding from slow and latent Fevers, which are generally mistaken for Vapours and Hysterics." Thus ran Dr. James's advertisement as set forth by the firm of Newbery. Dr. Johnson said of James, who was a Fellow of the Royal College secured everywhere in the country. Dr. Reynolds urged the necessity of very close observation of cases of peripheral neuritis for the detection of two symptoms which may be considered specially to point to arsenic—pigmentation and keratosis. He also drew attention to the large quantity of arsenic sometimes present in reduced iron—B.P. ferrum redactum in some cases having been found to contain as much as 1 per cent. of arsenic. Many practitioners have found special advantage from administering iron in this form in cases of anæmia, and it is possible that this beneficial result arises from the fact that with every grain of reduced iron a dose equivalent to a minim of liquor arsenicalis is administered. The possibility, at any rate, deserves to be noted.

## THE INTERNATIONAL CONGRESS OF GYNÆCOLOGY AND OBSTETRICS.

The Fourth International Congress of Gynæcology and Obstetrics will be held in Rome under the patronage of the King of Italy from Sept. 15th to the 21st, 1902. The subjects on which papers are to be read are—(1) Medical Indications for Interrupting Pregnancy; (2) Hysterectomy for Puerperal Infection; (3) Genital Tuberculosis; and (4) Surgical Treatment of Cancer of the Uterus. The general president is Professor Ercole Pasquali of Rome; the presidents of the obstetrical and gynæcological sections are respectively Professor Morisani and Professor Mangiagalli; the general secretary is Professor Ernesto Pestalozza, 60 Via Alfani, Florence; the treasurer is Dr. C. Micheli, 127 Via Rasella, Rome; and the honorary secretary for Great Britain and Ireland is Dr. William J. Gow, 27, Weymouth-street, London, W. The membership subscription, including the right to receive the printed transactions of the congress, is 25 lire (£1). Relatives of members will be admitted to the official entertainments on the payment of 10 lire (8*s.*). These sums may be sent either to Dr. Micheli or to the secretaries for the countries to which members belong. The time assigned to each paper is not to exceed 15 minutes. Intending readers of papers are requested to send the titles, and if possible short summaries, to the general secretary before the end of May.

## THE COAL SMOKE ABATEMENT SOCIETY.

The third annual report of this excellent society shows an increase in good work of which the society may well be proud. We are pleased to see that the borough councils are more alive to the nuisance of foul, dirty smoke than were the old vestries. Still, they might accomplish even more than they do. For instance, 225 nuisances were reported to the Public Health Committee of Chiswick, but only eight summonses were issued. The Coal Smoke Abatement Society at present has two inspectors working under it and the council of the City of Westminster has appointed two of its own. We advise everyone to join this society and to read the report of Sir William Richmond's speech at the annual meeting of the society which was held on Nov. 20th, 1900, at Grosvenor House. There the reader will find facts and figures, some of which we have quoted above, which will make him grateful to the society and profoundly disgusted with magistrates and local authorities. The latter, though less apathetic than the vestries are still not as active as they might be and the former inflict most inadequate fines. As we have pointed out over and over again the excuse about not being able to get Welsh coal is nonsense. If manufacturers like they can easily make their furnaces smokeless. When they find that it is better for their pockets that the furnace should be so they take steps to make it smokeless, as in the case of the Nottingham lace makers. If, then, magistrates will only fine all offenders as heavily as possible the said offenders will manage to get smokeless furnaces, and we shall be spared such days as March 6th and 11th, when London resembled portions of the Underground Railway in its worst days.

## SMALL-POX IN LONDON.

The returns for the past week show the following figures: on Saturday, March 15th, there were 43 fresh cases notified and removed; on Sunday, the 16th, there were 45 fresh cases; on Monday, the 17th, there were 82 fresh cases; on Tuesday, the 18th, there were 52 fresh cases; and on Wednesday, the 19th, there were 71 fresh cases.

## POST-MORTEM EXAMINATIONS IN UNION HOSPITALS.

At the weekly meeting of the Lurgan Board of Guardians held on March 6th one of the members of the board complained that the medical officers of the workhouse had been in the habit of making post-mortem examinations. The medical officer of the workhouse hospital, Dr. J S. Darling, having been sent for, said that post-mortem examinations were occasionally held on patients who had died there. He had no explanation to offer; if the cause of death was a doubtful one and where the patient had no friends he made a post-mortem examination. He had made six during the past six months and three during the past month. There might be months without such an examination being made, but it was never done with annoyance to any friends On being asked if he would refrain from making necropsies, Dr. Darling said that he would if the guardians made an order and the Local Government Board sanctioned it. If the board of guardians left the matter in his hands it would only be in exceptional cases where there was a genuine need that he would make a post-mortem examination. Notwithstanding this extremely fair promise the guardians decided by a large majority that no more post-mortem examinations should be held unless with the consent of the board. It is a great pity that the medical officer of the Lurgan workhouse hospital should be hampered in his efforts (in which, we are informed, he has always considered the feelings of the friends of patients) to verify the diagnosis of disease by post-mortem examination. Without such a method the science of medicine would soon come to a complete standstill.

## ACHONDROPLASIA.

In the March number of the *Polyclinic* an interesting account of a case of achondroplasia is contributed by Mr. James Cantlie. The patient, a girl, aged 13 years, presented the usual symptoms of conspicuously short upper and lower limbs. When she sat by the side of a healthy well-grown girl of normal development the two girls appeared to be of about the same height, but when they assumed the erect posture there was a great disparity on account of the shortness of the patient's lower limbs. Similarly her upper limbs were greatly wanting in length, the tips of the fingers, as the arms hung by the sides, hardly reaching below the iliac crests. Her head appeared to be relatively large, but it was to the defective elongation of the limbs associated with a trunk of approximately normal size that she owed her peculiar aspect. Mr. Cantlie points out that achondroplasia, though sometimes described as fœtal rickets or fœtal cretinism, is essentially distinct from either of these conditions. His patient, though helpless in many particulars because of the maldevelopment of her limbs, was a very intelligent girl whose facial aspect and general bearing were far removed from the mental dulness of cretinism. Achondroplasia is an arrested development in certain portions of the bony skeleton, the parts affected being those which are normally ossified in cartilage during the earlier months of fœtal life. Bones their existing contracts A letter was received, signed by all the public vaccinators, drawing attention to some remarks which the chairman was stated to have made at the last meeting and requesting an apology The chairman stated he had no intention of hurting the feelings of these gentlemen and he was very sorry if he had done so

## THE CHELTENHAM EAR, EYE, AND THROAT HOSPITAL

AT the annual general meeting of subscribers to the above institution held on March 5th two very important motions were carried The first was as follows "That the hospital in future shall be a free hospital" The motion for this purpose was introduced by Mr G A Cardew in an admirable speech "*If,' he said, "subscribers asked*, 'What shall we get for our subscriptions?' we can reply, 'Exactly the same as before, except that you will be able to send in patients regardless of time and not have to tell them to wait until your next stock of tickets arrives'" We like Mr Cardew's cheery optimism, for there is a class of subscriber who will think "What good do I get by subscribing when anyone else who does not subscribe can recommend patients as well as myself?' However, this class of subscriber is rare We congratulate the authorities of the hospital on their decision The other important resolution at which the meeting arrived was to appoint a resident medical officer The brunt of the work, exclusive of dental matters, has hitherto been borne by Dr J A Bower, the honorary surgeon, although he has had the assistance of Mr C E Abbott as anæsthetist and in a measure as assistant surgeon Every hospital should, however, in our opinion, possess a resident medical officer, and we earnestly hope that the additional £200 per annum, which the appointment of such an officer will involve, will not be sought for in vain

## THE HEREDITARY SEQUELÆ OF ALCOHOLISM

DR. T D CROTHERS of Connecticut contributes to the January number of the *Quarterly Journal of Inebriety* a valuable preliminary report on Heredity and Alcoholism, containing some of the main conclusions reached by a committee of physicians which was appointed at a Medical Temperance Congress held in the United States in 1888 and of which he was chairman The collection of material for the report, says Dr Crothers, has gone on during 13 years and up to the date of publication of the article fairly accurate histories had been collected of 1744 cases of inebriety The majority of these cases (about 1300) had come under Dr Crother's personal care and observation The facts were carefully ascertained and collected, and the inquiry was not limited to heredity alone but included "every condition and circumstance which could have an etiological bearing in the development of inebriety In a few cases the existence of inebriety or of mental disorder in the parents was carefully concealed *and had to be ascertained indirectly*, or was at first denied and subsequently disclosed "The central conclusion which cannot be stated too strongly,' says Dr Crothers "is that the injury from alcohol to the cells and nerve tissues is transmitted to the next generation with absolute certainty in some form or other'—i e as a drink craving a neurosis or a mental defect. Of the 1744 inebriates with trustworthy histories 1080 had a direct history of alcoholic heredity, 390 cases were traceable to bodily diseases injuries or shocks, 180 were attributable to starvation and poisoning, while 85 cases were due to ignorance, bad surroundings and imitation (mental contagion) In only the remaining nine cases were the causes so complex or so obscure that no classification could be made of them Regarding the 1080 patients with a direct alcoholic heredity Dr Crothers writes "In most [of these] there seemed to be largely transmitted a special predisposition to find relief in spirits, or a mental diathesis (instability) with want of self control, and often a species of psychical pain and unrest which found greatest relief from the use of spirits" In 430 of these patients there was hereditary transmission of the drink craving from the parents and in 224 from the grandparents (atavic heredity), while in 290 cases some degree of psychopathic heredity or mental abnormality could also be traced in the parentage While a study of the family records of these cases show that some members of these families were endowed with ability and even brilliancy in the fields of theology, politics, music, law, and art, many others showed criminal or vagrant tendencies or were otherwise mentally and morally defective and sank rapidly into the lower strata of social life In 49 instances the inebriates belonged to the "epileptoid' class both as regards personal symptoms and hereditary antecedents Such persons were characterised by "alcoholic outbreaks of stormy or cyclonic development," not necessarily or strictly periodic, developing suddenly and disappearing with little or no trace behind The ancestors of these persons were always noted for their sudden explosive nerve energy persons whose whole conduct throughout life was an alternation of wild extremes continually changing in politics in religion, and in business, always leading forlorn hopes and always defeated, physically suffering from disease and making remarkable recoveries, at one time using spirit then changing to other remedies and always under an obsession' Among the female members of these families were many neurotic individuals addicted to drugs, Christian scientists and faith curers, and mental or moral invalids given to secret drinking Finally, various groups of inebriates were met with who either took to drinking as though driven by fate, at the same ages when their parents took to drink, or who manifested precocious sexual instincts or an abnormal craze for food as well as drink, or who readily became addicted to the morphia habit. The far reaching morbid effects of alcoholism were thus clearly proved

## ARSENIC IN BEER AND IN REDUCED IRON.

ON March 10th Dr E S Reynolds of Manchester gave some interesting evidence, which we reported last week (p 786) before the Royal Commission on Arsenical Poisoning Manchester and its neighbourhood contain large numbers of important breweries which used arsenical glucose and invert sugar supplied during 1900 by Messrs Bostock and Co, and as is well known Manchester suffered most severely during the epidemic of arsenical beer poisoning which then occurred It was to be expected that during the interval which has since elapsed no precaution would be omitted which Manchester brewers could take to eliminate arsenic not merely from brewing sugars but from malt which in certain neighbourhoods owing to the fuel used appears to be capable of taking up arsenic This seems to have *been the case and Dr Reynolds testified that in some Man*chester beers no arsenic can now be found by the most delicate test, while the highest quantity has been under $\frac{1}{100}$th of a grain per gallon Dr Reynolds to whom belongs the credit of first discovering the cause of the Manchester outbreak in 1900 informed the Commission that alcoholic neuritis as understood for years in Manchester, has almost disappeared and that skin pigmentation and herpes formerly common in cases where neither arsenic nor alcohol was suspected as a cause have largely diminished, and he added the interesting observation that cases of "alcoholic heart to which a great deal of attention has been paid in Manchester and which has formed the subject of several monographs can now no longer be found at all It is evident however, from the facts reported by Dr J F Hodgson regarding cases at Halifax that similar freedom of beer from arsenic has not been contemporary described as "a fraud on the poor as it leads them to believe from its description that the addition of milk enriches it [butter], instead of impoverishing it." And where is this sort of thing, this mixing, to be stopped? For as matters stand at present disclosure would permit the addition of 40 or even more per cent. of water if it could be successfully incorporated. Mr. Justice Wills has given his opinion that this incorporation of milk with butter is done with the object of making "a spurious profit." If that is so, surely the law needs to be amended in order to stop this practice Average milk contains 88 per cent. of water, so that adding milk to butter is tantamount to adding water to it. The unjust difference is that the man who adds water to his butter cannot get off by declaring that such is the case, while the man who adds milk can, although by so doing he may raise the water to nearly 30 per cent. Anything more anomalous than that we cannot imagine. If something is not done soon the butter trade will be completely demoralised by this regrettable concession.

## SMALL-POX AT CHARTERHOUSE SCHOOL.

THE alarming rumours of small-pox at Charterhouse chool, Godalming, and the startling statements that have ppeared in the press do not appear to have been fully justified by the facts. Upon inquiry into the circumstances we find the following to be the true history of the case. On Dec. 24th one of the boys while at home developed spots which had all the characteristics of variola. An experienced physician pronounced the case to be one of small-pox and it was so treated and registered as such by the medical officer of health. The boy had been vaccinated some three weeks before the appearance of the rash. On Feb. 22nd the boy returned to Godalming and on March 5th on account of some inflammation of the eye he was sent into the school sanatorium, where on March 7th a rash was observed of exactly the same character as that seen in December. In the opinion of three skilled medical men these spots were due to small-pox and, though the case was anomalous, there was nothing else to do but to treat the boy as a patient suffering from variola. As a matter of course the most rigorous precautions have been taken and in all cases revaccination, where required, has been enforced The occurrence has, naturally enough, excited some criticisms on the medical and nursing conditions at Charterhouse School that may be more or less disregarded, but we think that it would be advisable for the authorities carefully to consider whether the matrons of the different houses are afforded sufficient skilled help in nursing boys under their care

## THE PSYCHOLOGY OF ANARCHISM.

IN the *Scottish Medical and Surgical Journal* for March Dr. George R. Wilson of Perth Asylum has published a brief and interesting paper on "Anarchism, the Insanity of Delusive Expedient," in which, after referring to the medico-psychological aspects of the case of Czolgosz (the assassin of the late President McKinley), the question is raised as to the "psychological significance of this social disease, anarchy, and whether we are quite justified in regarding it as consistent with sanity" The intelligence of the anarchist was, it is argued, probably above the average of those of his class in society, but such intelligence was marred by characteristic defects Of these, the fundamental defect was a morbid sense of injustice and oppression, a tendency to regard civilised institutions as wrong, unjust, and tyrannical. It was the creed of the weakling mind which found the conditions of life too hard and which lacked courage and perseverance to face the situation and to redeem itself from it. The anarchist regardec
institutions and the accepted opinion and customs
as "systematised engines of partiality and cruelty,"
tude of mind which closely bordered on that of the
and which readily developed delusions of
Another "stigma" was characteristic of the
mind—viz., an excessive tenacity of belief which w
unto an insane delusion in that the mind was
seeing and examining the grounds for its creed or l
it found the doctrines of anarchy satisfactory to its
inclinations and accepted them without thinking
anarchist was a reformer whose ideas ran counter to
tendencies of social evolution and who, finding his
ings and expedients futile to gain converts, did
hesitate to kill His criminality was found in his
instincts and his insanity was obvious in its
"the ineptitude of the act in relation to the end
Moreover, the mind of the anarchist was unduly
"suggestion" and depended for its existence upon inte
course with like minds. When social inequality was
the ruling powers were corrupt and despotic anarchy might
tend to flourish as a social disease; but with the progress
social evolution, which, while it rendered the struggle for
life keener, tended also to make it more fair and just to the
competitors and helped to shelter and to guard the we
minded from the special vices and dangers to which they
might otherwise succumb, anarchy might be
expected to diminish.

THE debate on the Nature and Origin of Cancer
was inaugurated by the Chelsea Clinical Society with
success on March 11th is continued in our column
week, the debate having been resumed on Tuesday
March 18th Owing to the amount of material at
society's disposal it has now been decided to hold a t
meeting on Tuesday next, March 25th, at which comm
cations will be received from Professor Adami of Mo
University, Montreal, and Mr. W. R. Gaylord of New Yo
while Professor R. T. Hewlett and Mr. D'Arcy Power
speak. The debate will then be closed by Dr. J. F. Payı
All members of the medical profession will be welcomed
the third meeting as at the others.

MR HENRY N. CUSTANCE, who has been secretary to the Metropolitan Hospital Sunday Fund since 1873, has resigned that post owing to ill-health. Sir Edmund Hay Currie, who was an originator of the fund and who has been one of its honorary secretaries since its formation, has consented to act as secretary, and Mr. R. A. Owthwaite, who has been associated with Mr. Custance throughout his period of service, will continue his connexion with the fund under Sir Edmund Hay Currie.

THE Second International Congress for Electricity
Medicine and Radiography will be held at Berne
Sept. 1st to the 6th, 1902, and the Second
Congress for the Prophylaxis of Syphilis and of V
Diseases will be held at Brussels between the same
We shall give further details of both meetings in a
issue.

HIS MAJESTY THE KING has announced that
Coronation he will entertain at dinner 500,000 of his
subjects at an expense of £30,000 from his privy purse.

HIS MAJESTY THE KING has appointed Dr. James
to be an Esquire of the Order of the Hospital of St. John
Jerusalem in England.

resulting from ossification in membrane are formed as usual, and the same is true of those which, formed in cartilage, remain mainly or entirely cartilaginous until after the sixth month or so of fœtal life But the parts which are ossified in cartilage in early fœtal life are stunted in their development, as if from premature arrest of the ossifying process This defect applies to the long bones of the limbs, the ribs, the pelvis, and the greater part of the base of the skull.

## THE DISTRIBUTION OF PLAGUE.

DURING the week ending March 2nd 15 cases and 8 deaths from plague have been reported throughout all Egypt. 7 cases and 3 deaths occurred at Tantah, 1 case was admitted to hospital at Abusir, 1 at Kom-el-Nur, and one at Mit-Ghamr. 4 cases and 4 deaths occurred in villages near Zifteh and 1 death out of hospital at Mehallet Abu Aly near Mehalla Kebir in the Gharbieh province. The disease shows a tendency to spread in some of the outlying villages of the province of Garbieh, but has assumed no serious proportions. Great difficulty is experienced, however, in obtaining early and trustworthy information about suspicious cases of illness in the villages in which the sanitary authorities are obliged to rely on the information afforded by the sanitary barbers These are recognised Government officials, but are unpaid, and it is to their interest to be on good terms with the omdehs, scheiks, and inhabitants of their villages. As they depend for their livelihood on the latter, who are generally more inclined to conceal any cases of infectious disease than to announce them, the barbers' information, as may be imagined, is not of a very trustworthy nature During the week ending March 9th 12 cases of plague and 4 deaths from the disease have occurred throughout all Egypt. 1 case and 1 death occurred at Tantah, 1 case at Abusir, 2 cases and 1 death at Nahtai, and 8 cases and 2 deaths at Kom-el-Nur. As regards The Mauritius telegrams from the Governor received at the Colonial Office on March 7th and 14th state that for the week ending March 6th there were 19 cases of plague, of which five proved fatal, and for the week ending March 13th there were 10 cases of plague, of which seven were fatal.

## ACETYLENE AS AN ILLUMINANT IN WARFARE.

A GOOD and easily managed illuminant, portable and yet capable of maintaining a clear and steady light for lengthened periods in spite of wind and rain, is a desideratum which medical officers have long sought for, though so far without any very conspicuous success On active service the surgeon's duties are often heaviest during the hours of darkness, and it would indeed be a priceless boon if a lamp could be devised which would in the first place enable him to search rapidly and effectually for the wounded after an engagement, and next would afford the indispensable light without which it is utterly impossible for him to do justice ither to his patients or to modern science. The subject of acetylene as an active service illuminator was taken up a year or two since by Dr Nikolaï who extolled an apparatus consisting of a generator of the size of a haversack which was connected with a burner and reflector by means of a long rubber tube This apparatus was described at length in the *Deutsche Militärarztliche Zeitschrift* for October, 1899, but in the number of that journal for January last there is an article by Dr. Reh pointing out what he regards as fundamental defects in the highly-praised invention. To begin with it is far too large and too heavy, requiring the exclusive services of a bearer, and next, besides being very fragile it is awkward to manipulate and by no means unlikely to explode. According to Dr. Reh an acetylene campaign lamp ought to be very light and yet strong and be capable of being carried either in the hand or attached to the waist-belt so that the bearer can at the same time fulfil his normal duty. After experimenting for over two years Dr. Reh has succeeded in constructing an acetylene lantern which, in his opinion, has answered all requirements under the most severe tests with regard to rain, wind, storm, and intense cold. Every stretcher-bearer, he considers, should be provided with one of these lamps, which are constructed so simply that any person of average intelligence can learn the management in a few minutes When extra light is needed for an operation or any other cause three or five of the lamps can be attached to portable stanchions, or if desired, larger lamps can be provided on the same principle, though Dr. Reh does not think that this is necessary.

## WHAT IS WATERED BUTTER?

IT seems to us that further legislation in regard to the control of the sale of butter is being attempted upon most unsatisfactory lines It has been recommended by a Departmental Committee of the Board of Trade that 16 per cent. of water shall be the limit of genuine butter. To this recommendation the obviously weak-kneed rider is added that in the event of a disclosure being clearly made to the purchaser that the butter contains more water than this no offence shall be deemed to have been committed. In that case obviously there would practically be no limit to the extent to which butter may be watered. We do not believe in this principle of "disclosure" at all. At any rate the principle is not calculated to save the pocket of the purchaser. Take the case of the so-called milk-blended butter which contains at least 25 per cent of water derived, it is said, from the milk worked into it. At first this was sold simply as "butter," but the High Court of Justice decided that it could no longer be sold as "butter" and thereupon the term "milk-blended butter" was ingeniously introduced. The fact, however, that it contains 25 per cent. of water is disclosed on the wrapper and the price is 1*s.* per pound, and the average purchaser thinks that he is getting genuine butter so much cheaper than before As a matter of fact he is the loser, for out of 16 ounces of the milk blend at least four ounces are water, and he who pays 1*s.* a pound for water is hardly wise in his generation. Of course, the "disclosure" does not help him out of the delusion; the average member of the public is not educated sufficiently to understand it The Food and Drugs Act was intended to protect the consumer not only against injurious elements in his food but against fraud also, a fact which even the Lord Chief Justice of England seems to have lost sight of, for he ruled on one occasion that glucose might be permitted in marmalade as it was quite a harmless addition So is water to milk. The only chance of affording the consumer effectual protection seems to us to be by the adoption of standards by the legislature Genuine butter must be defined in the same way as genuine milk has been defined, but we think that a mistake is made in the case of the former by placing the limit upon the amount of water. Why not, instead, demand a standard amount of butter-fat in genuine butter? In other words, butter containing less than a prescribed amount of butter-fat should be deemed not to be genuine In the case of milk the standard is not based upon the amount of water permissible in it, but upon the amount of fat and the solids not fat respectively, and in the same way the proportion of fat should determine the genuineness or not of butter. Provided that this standard was reasonably high "milk-blended butter" would obviously come outside the definition of genuine butter As it is our authorities seem chary to initiate any definite action which shall put a stop to what Sir Edward Strachey has in a vigorous and timely letter to a

# THE METROPOLITAN WATER-SUPPLY.

## IV.[1]

### THE SOUTHWARK AND VAUXHALL WATERWORKS COMPANY: SOME QUESTIONS FOR THE PRESIDENT OF THE LOCAL GOVERNMENT BOARD.

EPIDEMIOLOGISTS ought possibly to be grateful to the former directors of the Southwark and Vauxhall Waterworks Company, for it was in consequence of the arrangements which they made that Dr. J. Snow was able to prove beyond the possibility of doubt that cholera was spread by means of water. The customers through whose sufferings this fact was established had no reason to be satisfied with the company, which "was purveying perhaps the filthiest stuff ever drunk by a civilised community." So the water was described by Mr. John Simon (now Sir John Simon, K.C.B.) in his report to the Right Hon. William Cowper, President of the Board of Health.[2] At that time the directors of the company declared the water to be "unexceptionably good" and the chairman contended that the works were capable of distributing from the Thames at Battersea a supply "inferior in no appreciable degree to the stream in any part of its course," and he protested against a change in the intake as "a wholly uncalled-for expenditure of capital." The Battersea station of the company still exists, but the intake has (in consequence of the powers of control exercised under the provisions of the Act of 1852) been long removed (to Hampton) and it was expected that before this time the old station would have been abandoned. It may be fair to state here that the directors of the Southwark and Vauxhall Waterworks Company, who said that the water which they supplied was of "unexceptionably good" quality, found support for their contention that they were not purveying the filthiest stuff possible, or at any rate that it was not unwholesome. "Gentlemen of deserved eminence as chemists (though, perhaps, not entitled to speak with equal authority on the causation of disease) were found willing to express opinions both that this water, nourishing a population of animalcules, would 'not be noxious' to health, and that we cannot in any part of the world connect the ravages of cholera 'with the quality of the water' consumed."[3] The water companies employed experts in those days. A description of the Battersea station of the Southwark and Vauxhall Company has been given in THE LANCET, of March 27th, 1897, p. 901, and it was then stated that the place would not be used after the completion of the alterations which were at the time in progress at Hampton. In these circumstances it was not deemed necessary to enter so fully into a description of all the details, as it might otherwise have been. "The sanitary arrangements," it was said, "are not strictly in accord with modern ideas." At that time a jakes or privy of the kind preferred by the late Colonel Sibthorpe was situated in the grounds.[4] The outlet of the other sanitary appliances discharged into the river Thames.

It happened that the new Hampton works were completed at the time at which repeated water famines in the East End of London had for a moment awakened the inhabitants from the state of good-tempered apathy in which they usually live, and even the President of the Local Government Board was moved to think that something ought to be done. He therefore requested Lord Llandaff's Commission which happened to be sitting at the time to consider a scheme of intercommunication between the companies mains—a scheme which had then recently been propounded by the representatives of the metropolitan water companies. The general principle of the scheme was recommended in Lord Llandaff's First Report, and an Act was passed to enable the work to be carried out under the supervision of the Local Government Board. The nature of the original scheme was explained in THE LANCET of Nov. 12th, 1898, p. 1287, when it was initiated, and a modification of it was afterwards recommended with the distinct proviso that the use of the Battersea station was to be a temporary measure, and it was clearly pointed out that this undesirable course was advocated as the lesser of two evils—the greater evil being the certainty that if it were not adopted the unfortunate customers of the East London Company would again suffer from the discomforts and the dangers of another water famine. The premises of the Southwark and Vauxhall Company ought never to have been allowed to fall so far short of modern requirements, but for years the directorate of the company carried on its business with the least possible outlay. The managers of the company of whom Sir John Simon wrote years ago have had their modern counterparts. A good specimen of the type appeared before the Llandaff Commission in the person of Sir Henry Knight, chairman of the company.[5] The ideas of this gentleman in regard to the necessity for large storage reservoirs were not in accord with the teaching of modern sanitarians. Mr. J. Parry, the engineer to the city of Liverpool, recently insisted on the fact that "there are some years in which the consumption [of water] becomes abnormally high through the influence of severe frosts in the winter and long droughts in the summer. I need scarcely point out," he adds, "that in any comparison between the quantity per day to be provided and the resources available to meet those demands these abnormal rates of consumption must not be overlooked." Sir Henry Knight said in the evidence which he gave before the Landaff Commission that such provision against abnormal demands was inadvisable. We do not profess to attach any value to the scientific opinion of Sir Henry Knight, but as unfortunately the London water companies have in too many cases been managed by men holding his views it may be worth while once for all to show how the matter of water-supply has been looked upon by such people. The following report from the shorthand notes will make this clear.

The CHAIRMAN (Lord Llandaff): I should like to hear from you what is within the control of the company. Supposing the company has been wanting in forethought, has not provided reservoirs enough, has not provided pumping power enough, has not provided duplicate mains and pumps when they ought prudently to be provided, is it to go on getting its water-rate although it supplies no water?

Sir HENRY KNIGHT: That would all depend as to whether the deficiency in any one of the circumstances which your lordship has mentioned is caused by any ordinary natural causes or came about from extraordinary natural causes. ...... I maintain that it is not in the interests of anybody that it [a company] should put itself in a position to meet causes which *may never arise at* all; that it would be a useless expenditure of capital and a waste of money.

The CHAIRMAN: Then you would have said that any company was acting foolishly which in 1897 provided itself with storage for such a year as 1898?—The WITNESS 1898 was an exceptional year.

The CHAIRMAN; Exactly; do not repeat it all over again, Is what I have just put to you a fair inference from what you have just said—1898 was an exceptional and extraordinary year not to be foreseen, therefore it would be absurd to require a company to provide itself for such a year as that?—The WITNESS · I do not say it would be absurd. I think it would be inadvisable.

The CHAIRMAN: Very well I will take the milder word inadvisable if you like.—The WITNESS · Because it would be a great expenditure of capital.

If the interests of the people of London had been as keenly looked after by the Local Government Board as the financial interests of the shareholders of the water companies have been studied by the directors of those undertakings the present state of the water-supply would have been vastly different from that which exists to-day. For many years the Southwark and Vauxhall Company did as little as possible in regard to improvements, but at last a time arrived at which circumstances forced them to give up their state of masterful inactivity. The following tabular statement shows the nature and amount of the chief changes which have taken place between December, 1896, and December, 1901 (Table I.).

From this table it is seen that during the last few years the storage capacity and the filtration area of the Southwark and Vauxhall Company have both been materially increased. A casual glance at the table, however, might probably cause a reader to come to a very erroneous conclusion as to the amount of the improvements which have taken place. The

### CHEMISTRY

There is not a more important or valuable branch of Medical education than Chemistry, and the rapid advancement this science has recently made, renders it equally interesting to men of general research Among the ancient physicians, this science, or rather art, as it then existed was held in high estimation, because they found considerable benefit to result from an application of its principles in their profession, notwithstanding the imperfect knowledge they possessed respecting its action, and the consequent disadvantages they must have experienced in its employment In our times, the great value of chemistry to medical practice is every day proved by the success which attends a just application of its principles, whether adopted for the purpose of discovering the cause of disease or of prescribing remedies for its cure It is, therefore now justly regarded as the ground work of all medical knowledge and it is also indispensably a most important part of surgical education, for chemistry alone is the only key to physiological investigation, and when the medical philosopher whether surgeon or physician, enters this wide field of inquiry, he must rely on chemistry as his guide and interpreter, provided he wishes to examine with success the sublime laws of Nature as displayed in organic life, or extort from her a confession of those general regulations by which her empire is governed The real importance of this science, as it now exists, is not only felt in every branch of the medical profession, but is observed to extend its influence to every class of society, hoisting its banners in every country, and rapidly enlisting active supporters in the common cause of useful knowledge

Sensibly feeling the importance of chemistry ourselves and the probable advantage of communicating on this subject with our professional readers, we shall devote a part of our pages every week expressly to the purpose, and in order to make our papers as beneficial as possible, we shall give them as a regular series on the elements of the science, detail simple and inexpensive methods of performing the necessary experiments connected with the subject, at the same time, introducing new and original matter as we proceed either in the way of theory or practice, as it becomes known in this country or any other —We have stated that we shall give our papers as a series, on the elements of chemistry, and detail simple methods of performing those experiments which are connected with our immediate subject, our reason for adopting this plan, is because we have observed many intelligent persons who have attentively studied the best chemical works and diligently attended chemical lectures ignorant of some of the first and most simple principles of the science—possessing only a knowledge of terms and phrases which they do not understand, or have not experience to apply, and this we can fairly attribute to the want of that personal experiment which is necessary to fix the subject permanently and usefully on the mind

We may here remark, that practical operation is as necessary to the study of chemistry, as dissection and personal observation are to the study of Anatomy for in either case no useful or permanent knowledge can be obtained without actual operation, and as the experiments in chemistry, as generally laid down in chemical works or shown in public lectures, cannot be made by inexperienced individuals we shall endeavour to give such as may easily be performed by every reader of our journal however ignorant he may be of practical chemistry, we thus hope to give to those who wish to study the science with success, an opportunity of doing it in the only way that can lead to advantage, namely, by personal experiment

In our next number we shall commence an inquiry into the nature and effects of *heat*

### *Danger of Smoked Provisions* ¹

M G KERNER, a physician at Stutgard has just discovered a new species of poison proceeding from smoked provisions It appears from experiments which he has made that such provisions become subject to a species of decomposition which renders them poisonous Sausages made with liver are most liable to it and the decomposition generally takes place towards the middle of April Doctor KERNER has ascertained that of 72 persons in a district of Wurtemburg who partook of smoked sausages 37 died in a short time, and the others continued ill for a longer or shorter period —*Ibid* ¹

## NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION

ON March 18th Lord Derby presided over the third general meeting of the members of the National Association for the Prevention of Consumption and other Forms of Tuberculosis at 20 Hanover square, London

Lord DERBY in moving the adoption of the report of the council of the association, said that they had now reached that stage when they must be contented with progressing quietly on the path of progress They had reason to congratulate themselves on the success of the British Congress on Tuberculosis held last year and special thanks were due to Mr Malcolm Morris who had worked so hard in the cause The records of that congress would mark a very distinct epoch in their knowledge of the science for which that association was formed In regard to the suppression of the habit of expectoration in streets and in public places he was bound to say from personal observation that those against whom their warnings were directed were making the most of their time while it lasted, and it was not possible to say that there was any diminution in the filthy and disgusting habit. It might be suppressed in time, but at present they could only caution the public He pointed out that a great deal had been done for the proper ventilation of work rooms, and he urged upon all interested to make the best use of the means within their reach to advance the objects of the association

SIR WILLIAM CHURCH seconded the motion and said that notification of tuberculous disease was an important point He did not mean that it would aid much in the interests of the individual but it would enable them to make out where tuberculous disease was especially prevalent. Whatever the differences amongst medical men might be they were all united in the opinion that it was the environment of people which was of such special importance in regard to the prevention of tuberculosis The work of the association fell into two classes—prevention and treatment Treatment appealed more strongly to the public than prevention but prevention was far the more important That point should not be lost sight of and the public should be instructed in the prevention of the disease

Dr ELDON PRATT having addressed the meeting Colonel the Hon W Le Poer Trench made a personal explanation in regard to his retirement from the council in the course of which he remarked that Mr Alabone had been removed from the Medical Register in consequence of the Profession considering him to be a visionary in regard to his cure for consumption

The motion was then put to the meeting and was declared to be carried

The following were elected members of the council —Dr Theodore Dyke Acland and Dr L A Weatherly Sir Alexander Kinloch Mr Edgar Sever Dr G Vivian Poore, Dr W H Corfield Dr Isambard Owen, Dr F W Burton Fanning Sir George Brown and Professor McFadyean

SIR WILLIAM BROADBENT in moving the vote of thanks to the chairman said that Mr Alabone was removed from the Register for advertising and not because of any opinion he held in regard to the treatment of tuberculosis

Mr MALCOLM MORRIS seconded the vote of thanks which was suitably acknowledged by the Chairman

The proceedings then terminated

BEQUESTS AND DONATIONS —Mr T Heap of Blackpool who recently gave £100 to the Victoria Hospital has just forwarded another £50 to the secretary of the hospital —The treasurers of the Middlesex Hospital have received from Miss Fen an £50 to help to defray the expenses of the cancer ward the analyst to the Local Government Board is not responsible for the statement on whose evidence is it made?

## ASYLUM REPORTS.

*London County Asylum, Claybury (Report for the year ending March 31st, 1901).*—The average number of patients resident during the year was 2496, comprising 1048 males and 1448 females. The admissions during the year amounted to 591—viz., 247 males and 344 females. Of these, 499 were first admissions. Dr. Robert Jones, the medical superintendent, states in his report that "a considerable rise has taken place in the reception of senile cases. Of all the admissions 18 per cent. were over 60 years of age," whereas in the previous year they were 10 per cent. "Many of these patients," adds Dr. Jones, "die from pure senile decay." There are many conditions, argues Dr. Jones, against the sending of such patients to the asylum; and yet they are difficult to treat at home or in an infirmary owing to habits of restlessness and wandering, especially at night, when supervision is not easy. "Their habits are defective and they are neither amenable to persuasion nor argument." Alcohol was determined to be the causal factor in 15 per cent. of the male and 11 per cent. of the female admissions, but the true proportion is regarded as higher. About one-third of the cases were attributed to heredity and previous attacks, and 10 per cent. to worry, anxiety, or adversity. "It is a grave feature that the insanity of nearly 10 per cent. of all the females who were admitted up to the age of 45 years was referable either to pregnancy, delivery, or lactation. This proportion gives 7 per cent. of all females admitted at all ages, and corresponds closely with that of the Lunacy Commissioners' Report of 1900." The number of patients discharged as recovered during the year amounted to 213—viz., 92 males and 121 females, or 8·5 per cent. of the average number resident. The deaths during the year amounted to 233—viz., 100 males and 133 females, or 9·3 per cent. as calculated on the same basis. Of the deaths five each were due to cancer and epilepsy, six to senile decay, 11 to influenza, 12 to bronchitis, 18 to cardiac disease, 22 to phthisis, 34 to pneumonia, 34 to colitis, 58 to general paralysis of the insane, and the rest to other causes. An outbreak of colitis during the year attacked 194 patients—viz., 69 males and 125 females—and resulted in 34 deaths, as above mentioned. "Special written instructions have been issued to all the attendants and nurses" having care of these cases of colitis. Suicide occurred in the case of one patient who was out with friends on trial, and this was the only instance among a considerable number of patients (nearly 30 per cent. of the admissions) with marked suicidal tendencies. The sub-committee of the asylum states in its report that the sewer drains of the whole asylum are being inlaid in concrete. The sum of £6980 has been expended during the year on repairs, and a further sum of £361 on additions and improvements. The Commissioners in Lunacy state in their report that the wards were in excellent order during their visit, the rooms bright and comfortable, the beds and dormitories clean and neat, and the personal appearance of the patients quite satisfactory. Regarding a special therapeutic measure—viz., the electric bath—Dr. Jones writes: "I have used the electric bath at Claybury for the past seven years and consider it a valuable remedy for adolescent melancholia and certain cases of stupor, alcoholic neuritis and lead neuritis."

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8615 births and 5573 deaths were registered during the week ending March 15th. The annual rate of mortality in these towns, which had been 24·4, 23·3, and 20·5 per 1000 in the three preceding weeks, further declined last week to 19·6 per 1000. In London the death-rate was 22·0 per 1000, while it averaged 18·4 in the 75 other large towns. The lowest death-rates in these towns were 6·6 in Handsworth, 9·7 in Hornsey, 10·2 in Wigan, 11·5 in Ipswich, 11·8 in Walthamstow, and 12·0 in King's Norton; the highest rates were 23·7 in Hastings, 23·9 in Burnley, 25·0 in Hanley, 25·2 in Huddersfield, 28·4 in Plymouth, and 29·6 in Merthyr Tydfil. The 5573 deaths in these towns last week included 617 which were referred to the principal zymotic diseases, against 582, 570, and 600 in the three preceding weeks; of these 617 deaths 187 were referred to measles 136 to whooping-cough, 100 to small-pox, 71 to diphtheria 50 to scarlet fever, 46 to diarrhœa, and 27 to "fever" (principally enteric). No death from any of these diseases was registered last week in Ipswich, Devonport, Burton upon-Trent, Handsworth, West Bromwich, or Stockton-on Tees; while they caused the highest death-rates in Willesden, Northampton, Hanley, Coventry, Leicester, Grimsby Burnley, and Huddersfield. The greatest mortality from measles occurred in Reading, Northampton, Grimsby Warrington, Burnley, Barrow-in-Furness, and Huddersfield from scarlet fever in South Shields; from diphtheria in Great Yarmouth, Hanley, Coventry, and Middlesbrough from whooping-cough in East Ham, Northampton, Aston Manor, Leicester, and Birkenhead; and from diarrhœa in Merthyr Tydfil. The mortality from "fever" showed n marked excess in any of the large towns. Of the 100 fata cases of small-pox registered last week, 81 belonged to London four to West Ham, three to East Ham, two to Croydon two to Willesden, two to Tottenham, and one each t Hornsey, Leyton, Hastings, Leicester, Liverpool, and Tynemouth. The number of small-pox patients under treatmen in the Metropolitan Asylums hospitals, which had been 1321 1309, and 1512 at the end of the three preceding weeks, had further risen to 1542 on Saturday, March 15th; 450 new cases were admitted during the week, against 502, 369, and 555 in the three preceding weeks. The number of scarle fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2206, against number decreasing from 3137 to 2283 on the 11 preceding Saturdays; 266 new cases were admitted during the week, against 219, 215, and 277 in the three preceding weeks. Th deaths referred to diseases of the respiratory organ in London, which had been 885, 733, and 589 in th three preceding weeks, further declined last week to 498 but were slightly above the corrected average number Influenza was stated to be the primary cause of 67 deaths in London last week, against 107, 103, and 89 in the thre preceding weeks. The causes of 57, or 1·2 per cent., o the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. Al the causes of death were duly certified in West Ham, Bristol Leicester, Nottingham, Salford, Leeds, Newcastle, and in 4 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn Bradford, Sheffield, and South Shields.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principa Scotch towns, which had been 22·6 and 25·4 per 1000 in th two preceding weeks, declined again to 23·6 during th week ending March 15th, but exceeded by 4·0 per 1000 th mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17·3 in Paisley and 19·8 in Leith to 30·2 in Dundee and 34·0 in Greenock. The 763 deaths in these towns included 23 which were referred to whooping-cough 23 to diarrhœa, 14 to measles, eight to scarlet fever seven to small-pox, six to diphtheria, and four to "fever." In all 85 deaths resulted from these principal zymotic diseases last week, against 75 and 69 in the two preceding weeks. These 85 deaths were equal to an annual rate of 2·6 per 1000, which was 0·4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping cough, which had been 23 and 20 in the two preceding weeks, rose again last week to 23, of which 12 occurred in Glasgow, seven in Aberdeen, and two in Leith. The deaths from diarrhœa, which had been 13 and 17 in the two preceding weeks, further rose to 23 last week, and included 11 in Glasgow, four in Dundee, three in Edinburgh, and three in Leith. The fatal cases of measles, which had been 19 and 14 in the two preceding weeks, were again 14 last week, five being registered in Dundee, four in Glasgow, and four in Greenock. The deaths from scarlet fever, which had been three, four, and seven in the three preceding weeks, further increased to eight last week, and included four in Glasgow, two in Edinburgh, and two in Greenock. The fatal cases of small-pox, which had been seven, 10, and two in the three preceding weeks, rose again last week to seven, and were all

first part of the present article has indicated wherein the fallacy may lie.

The East London Waterworks Company has by an arrangement made for that purpose with the Southwark and Vauxhall ompany of late derived water from the Battersea station of he latter company. It does not appear that the water so pplied is accounted for as distributed by the Southwark ompany. If water filtered at the Battersea station is used in the East London district and not for the supply of the Southwark Company's customers, and if still the Southwark Company is credited with the use of the Battersea filter-beds, it is evident that statistics founded on erroneous data are worse than valueless—they are misleading. This point should be made quite clear. Under the column giving the figures representing details of supply, reservoir capacity, and filtration area for the month of December, 1901, it is seen that the daily average supply in gallons was 28 819 380, the storage reservoir capacity is given as 436,000,000 gallons and the acreage of filter-beds as 31¾. Was the whole of that storage reservoir capacity used for the customers of, the Southwark Company, and were all the filter-beds used for the purification of the water supplied to them? Or were some of the filter beds used for the purification of water distributed by the East London Company? The monthly report of the Water Examiner does not give the information necessary to solve these problems. We must therefore leave these questions unanswered for the time and pass on to note the quality of the water supplied during the year 1901 by the Southwark Company. In order to present this information in the most convenient way a table has been drawn up (Table II.) which makes it easy to compare the amount of organic carbon and the amount of organic nitrogen found by Dr T. E Thorpe to be present in water supplied by the Southwark, the New River, and the Kent companies respectively. During the whole of the year it appears that only 12 complete analyses were made of the water supplied by the two last-named companies and 13 of the water supplied by the Southwark Company.

The table shows clearly enough that throughout the whole of the year the water supplied by the Southwark and Vauxhall Company whenever it was examined contained more organic carbon and more organic nitrogen than the specimens of water taken from the mains of the New River Company and of the Kent Company. It shows also that the water supplied by the Southwark Company contained more organic carbon and more organic nitrogen on Dec. 30th than on Dec 9th. The water was worse at the later date as a result of the increased impurity of the Thames during a time at which the river was in flood. The marked superiority of the Kent deep well water is apparent. It may seem curious that at the Llandaff Commission one of the experts employed by the water companies gave evidence to the effect that well water was dangerous, but on being pressed on the matter by the Chairman he referred to the case of the Caterham well which a workman, who was suffering from typhoid fever, had defiled by his alvine evacuations—a case which apparently did not convince Lord Llandaff that well water was necessarily dangerous.

TABLE II.—*Showing the Results of Analysis Expressed in Parts per 100,000 of Organic Carbon and of Organic Nitrogen in the Water supplied by the Southwark and Vauxhall Waterworks Company, the New River Company, and the Kent Company in each Month of the Year 1901 (Compiled from the Reports of the Results of Analysis made by Dr. T. E. Thorpe, F.R.S., on behalf of the Local Government Board.)*

* The increase in the organic matter is said to have been due to the admixture of the water of another company.

The Report of the Water Examiner contains month after month a general statement to the effect that the Southwark and Vauxhall Company has the means during floods of pumping from the gravel beds adjoining the Thames, "and this is practically equivalent to an addition to their storage resources" More complete information on this subject would be of interest

Is the President of the Local Government Board acquainted with the present sanitary condition of the Battersea station of the Southwark and Vauxhall Waterworks Company?

Does the President of the Local Government Board consider that the Battersea station of the Southwark and Vauxhall Company is suitable for the purpose for which it is used? If not, has any representation to that effect been made to the Southwark and Vauxhall Company or to the East London Waterworks Company?

Does the President of the Local Government Board know if any, and if so how much, water from Battersea was distributed by the East London Company during each month of the year 1901 and during the months of January and February of the present year? In the case of water distributed by any company is that company responsible for the quality of the water distributed?

Has the attention of the President of the Local Government Board been called to a statement which is frequently made in the reports of the Water Examiner that "all the samples of water collected at the works of the companies were efficiently filtered"? Does the analyst appointed by the Local Government Board examine samples of water taken at the works of the companies? Has he ever examined one specimen taken at the works of any company? If so, when did he do so? And were the results of the analysis published in the report of the Water Examiner? If the analyst appointed by the Local Government Board does not take samples of water at the works of the companies is he responsible for the statement that "all the samples collected at the works of the companies were efficiently filtered"? If the analyst to the Local Government Board is not responsible for the statement on whose evidence is it made?

## ASYLUM REPORTS.

*London County Asylum, Claybury* (*Report for the year ending March 31st, 1901*).—The average number of patients resident during the year was 2496, comprising 1048 males and 1448 females. The admissions during the year amounted to 591—viz., 247 males and 344 females. Of these, 499 were first admissions. Dr. Robert Jones, the medical superintendent, states in his report that "a considerable rise has taken place in the reception of senile cases. Of all the admissions 18 per cent. were over 60 years of age," whereas in the previous year they were 10 per cent "Many of these patients," adds Dr. Jones, "die from pure senile decay." There are many conditions, argues Dr. Jones, against the sending of such patients to the asylum; and yet they are difficult to treat at home or in an infirmary owing to habits of restlessness and wandering, especially at night, when supervision is not easy "Their habits are defective and they are neither amenable to persuasion nor argument." Alcohol was determined to be the causal factor in 15 per cent. of the male and 11 per cent of the female admissions, but the true proportion is regarded as higher. About one-third of the cases were attributed to heredity and previous attacks, and 10 per cent. to worry, anxiety, or adversity. "It is a grave feature that the insanity of nearly 10 per cent. of all the females who were admitted up to the age of 45 years was referable either to pregnancy, delivery, or lactation. This proportion gives 7 per cent. of all females admitted at all ages, and corresponds closely with that of the Lunacy Commissioners' Report of 1900." The number of patients discharged as recovered during the year amounted to 213—viz., 92 males and 121 females, or 8·5 per cent. of the average number resident. The deaths during the year amounted to 233—viz., 100 males and 133 females, or 9·3 per cent as calculated on the same basis. Of the deaths five each were due to cancer and epilepsy, six to senile decay, 11 to influenza, 12 to bronchitis, 18 to cardiac disease, 22 to phthisis, 34 to pneumonia, 34 to colitis, 58 to general paralysis of the insane, and the rest to other causes. An outbreak of colitis during the year attacked 194 patients—viz., 69 males and 125 females—and resulted in 34 deaths, as above mentioned. "Special written instructions have been issued to all the attendants and nurses" having care of these cases of colitis. Suicide occurred in the case of one patient who was out with friends on trial, and this was the only instance among a considerable number of patients (nearly 30 per cent. of the admissions) with marked suicidal tendencies The sub-committee of the asylum states in its report that the sewer drains of the whole asylum are being inlaid in concrete The sum of £6980 has been expended during the year on repairs, and a further sum of £361 on additions and improvements. The Commissioners in Lunacy state in their report that the wards were in excellent order during their visit, the rooms bright and comfortable, the beds and dormitories clean and neat, and the personal appearance of the patients quite satisfactory. Regarding a special therapeutic measure—viz, the electric bath—Dr. Jones writes: "I have used the electric bath at Claybury for the past seven years and consider it a valuable remedy for adolescent melancholia and certain cases of stupor, alcoholic neuritis and lead neuritis."

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8615 births and 5573 deaths were registered during the week ending March 15th The annual rate of mortality in these towns, which had been 24 4, 23·3, and 20·5 per 1000 in the three preceding weeks, further declined last week to 19 6 per 1000. In London the death-rate was 22·0 per 1000, while it averaged 18·4 in the 75 other large towns. The lowest death-rates in these towns were 6·6 in Handsworth, 9 7 in Hornsey, 10 2 in Wigan, 11·5 in Ipswich, 11·8 in Walthamstow, and 12 0 in King's Norton; the highest rates were 23 7 in Hastings, 23·9 in Burnley, 25 0 in Hanley, 25·2 in Huddersfield, 28 4 in Plymouth, and 29 6 in Merthyr Tydfil. The 5573 deaths in these towns last week included 617 which were referred to the principal zymotic diseases, against 582, 570, and 600 in the three preceding weeks; of these 617 deaths 187 were referred to measles, 136 to whooping-cough, 100 to small-pox, 71 to diphtheria, 50 to scarlet fever, 46 to diarrhœa, and 27 to "fever" (principally enteric). No death from any of these diseases was registered last week in Ipswich, Devonport, Burton-upon-Trent, Handsworth, West Bromwich, or Stockton-on-Tees; while they caused the highest death-rates in Willesden, Northampton, Hanley, Coventry, Leicester, Grimsby, Burnley, and Huddersfield. The greatest mortality from measles occurred in Reading, Northampton, Grimsby, Warrington, Burnley, Barrow-in-Furness, and Huddersfield; from scarlet fever in South Shields; from diphtheria in Great Yarmouth, Hanley, Coventry, and Middlesbrough; from whooping-cough in East Ham, Northampton, Aston Manor, Leicester, and Birkenhead; and from diarrhœa in Merthyr Tydfil. The mortality from "fever" showed no marked excess in any of the large towns Of the 100 fatal cases of small-pox registered last week, 81 belonged to London, four to West Ham, three to East Ham, two to Croydon, two to Willesden, two to Tottenham, and one each to Hornsey, Leyton, Hastings, Leicester, Liverpool, and Tynemouth. The number of small-pox patients under treatment in the Metropolitan Asylums hospitals, which had been 1321, 1309, and 1512 at the end of the three preceding weeks, had further risen to 1542 on Saturday, March 15th; 450 new cases were admitted during the week, against 502, 369, and 555 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital at the end of the week was 2206, against numbers decreasing from 3137 to 2283 on the 11 preceding Saturdays; 266 new cases were admitted during the week, against 219, 215, and 277 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 885, 733, and 589 in the three preceding weeks, further declined last week to 498, but were slightly above the corrected average number. Influenza was stated to be the primary cause of 67 deaths in London last week, against 107, 103, and 89 in the three preceding weeks. The causes of 57, or 1 2 per cent., of the deaths in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, Salford, Leeds, Newcastle, and in 46 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Blackburn, Bradford, Sheffield, and South Shields.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 22·6 and 25 4 per 1000 in the two preceding weeks, declined again to 23·6 during the week ending March 15th, but exceeded by 4·0 per 1000 the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 17·3 in Paisley and 19·8 in Leith to 30·2 in Dundee and 34·0 in Greenock. The 763 deaths in these towns included 23 which were referred to whooping-cough, 23 to diarrhœa, 14 to measles, eight to scarlet fever, seven to small-pox, six to diphtheria, and four to "fever." In all 85 deaths resulted from these principal zymotic diseases last week, against 75 and 69 in the two preceding weeks. These 85 deaths were equal to an annual rate of 2 6 per 1000, which was 0 4 per 1000 above the mean rate last week from the same diseases in the 76 large English towns. The fatal cases of whooping-cough, which had been 23 and 20 in the two preceding weeks, rose again last week to 23, of which 12 occurred in Glasgow, seven in Aberdeen, and two in Leith. The deaths from diarrhœa, which had been 13 and 17 in the two preceding weeks, further rose to 23 last week, and included 11 in Glasgow, four in Dundee, three in Edinburgh, and three in Leith. The fatal cases of measles, which had been 19 and 14 in the two preceding weeks, were again 14 last week, five being registered in Dundee, four in Glasgow, and four in Greenock The deaths from scarlet fever, which had been three, four, and seven in the three preceding weeks, further increased to eight last week, and included four in Glasgow, two in Edinburgh, and two in Greenock. The fatal cases of small-pox, which had been seven, 10, and two in the three preceding weeks, rose again last week to seven, and were all recorded in Glasgow The deaths from diphtheria, which had been six, one, and seven in the three preceding weeks, declined again last week to six, and included three in Glasgow, where two of the four fatal cases of "fever" were also registered The deaths referred to diseases of the respiratory organs in these towns, which had been 214 and 230 in the two preceding weeks, declined again last week to 189, but were 16 above the number in the corresponding period of last year The causes of 13 or nearly 2 per cent, of the deaths in these eight towns last week were not certified

### HEALTH OF DUBLIN

The death rate in Dublin, which had been 28 6 and 29 7 per 1000 in the two preceding weeks, declined again to 20 6 per 1000 during the week ending March 15th During the past four weeks the death rate has averaged 28 1 per 1000 the rates during the same period being 26 0 in London and 22 3 in Edinburgh The 150 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 66 from the number in the preceding week, and included eight which were referred to the principal zymotic diseases, against 13 in each of the two preceding weeks, of these, four resulted from measles, two from scarlet fever, one from "fever," and one from diarrhœa These eight deaths were equal to an annual rate of 1 1 per 1000, the zymotic death rates during the same period being 3 1 in London and 1 3 in Edinburgh The fatal cases of measles, which had been three, one, and six in the three preceding weeks, declined again last week to four The 150 deaths in Dublin last week included 21 of children under one year of age and 37 of persons aged upwards of 60 years, the deaths of infants and of elderly persons were respectively 11 and 38 less than the numbers in the preceding week No death from violence was registered during the week, two inquests were recorded, and 54, or more than one third, of the deaths occurred in public institutions The causes of eight, or more than 5 per cent, of the deaths in Dublin last week were not certified

## THE SERVICES

### ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified —Staff Surgeons G T Collingwood to the *President*, additional for service at Deptford Victualling yard, Charles Strickland to the *Aboukir*, and Hamilton Meikle to the *Vengeance* Surgeons Walter P Dyer to the *Aboukir*, George Gibson to the *Nile*, Harold E Fryer, Algernon C Bean, and Warren G Westcott to the *Hawke*, for duty on the voyage home, and A. J Wernet to the *Pembroke*, additional, to be lent for service at Deptford Victualling yard

### ROYAL ARMY MEDICAL CORPS

Major T McCulloch has been appointed Deputy Assistant Director, Army Medical Department, at Headquarters, vice Major W G Macpherson

Colonel J F Supple C B, has been appointed Principal Medical Officer, Meerut District

Major D R. Hamilton has arrived at Colchester Captain R. S H Luhr is appointed for duty in the Home District. Captain A R. O Flaherty is appointed for duty with the 4th Battalion the East Surrey Regiment, ordered to South Africa. Lieutenant H E M Douglas, V C, D S O, is appointed for duty in the Home District

### INDIA AND THE INDIAN MEDICAL SERVICES

Colonel A Scott Reid has been appointed to succeed Surgeon General Franklin as Inspector General of Civil Hospitals in the Punjab Colonel Joubert succeeds Colonel Hutcheson in a similar capacity in the North West Provinces and Oudh Colonel Geoffrey Hall succeeds Colonel Scott Reid as Administrative Medical Officer and Sanitary Commissioner in the Central Provinces

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon Lieutenant Colonel E Shedd having resigned his Volunteer appointment ceases to belong to the Army Medical Reserve of Officers

### IMPERIAL YEOMANRY

Surgeon Captain G H S Daniell of the Dorset (Queen's Own), and Surgeon Captain P B Mackay, of the Yorkshire Dragoons (Queen's Own), *resign their commissions and* receive new commissions subject to the provisions of the Militia and Yeomanry Act, 1901, each retaining his present rank and seniority

### VOLUNTEER CORPS

*Royal Engineers* 1st London Edward Coldridge Roberts to be Surgeon Lieutenant *Rifle* 5th Volunteer Battalion the Royal Scots (Lothian Regiment) Surgeon-Captain J Mill to be Surgeon Major 1st Volunteer Battalion the Norfolk Regiment James Morrison Gardiner Bremner to be Surgeon Lieutenant. 2nd Volunteer Battalion the Durham Light Infantry Surgeon Lieutenant R E Brown resigns his commission 5th Volunteer Battalion the Durham Light Infantry Surgeon Captain A. A Abraham to be Surgeon Major

### SOUTH AFRICAN WAR NOTES.

Civil Surgeon Newton is reported to be improving

The following officers have been discharged from hospital to duty —Captain J D Alexander, R A.M C, Lieutenant P S O Reilly R.A M C, Lieutenant R H Lloyd, R A M C Lieutenant J W West, R A M C, and Lieutenant C D Myles Civil Surgeons Williams, Dee, Vaux, Jordan, Scott, and Lynch

### SOUTH AFRICAN AFFAIRS AND THE WAR

A great deal has taken place, although but little of it has much medical interest or significance, during the brief interval that has elapsed since we last referred to the events of the war We may shortly enumerate what has occurred The defeat of the force under General Lord Methuen at Tweebosch with the capture and subsequent release of his lordship who was seriously wounded, the grave and critical condition of Mr Cecil Rhodes, the increased, if fitful, activity of the Boer forces in the field, the widespread prevalence of enteric fever in South Africa, the improved sanitary state of the refugee camps, the arrival *in this country of large batches of* sick and wounded officers and men from South Africa, and the embarkation of reinforcements for the seat of war In addition to the foregoing there has been a debate in Parliament on war contracts involving what would have been a vote of censure on the Government on its conduct of the war had the Opposition succeeded in carrying its resolution This succinctly summarises the history of recent events which, *taken as a whole, have made up a somewhat* exciting time In the course of the late debate in the House of Commons it may be remarked that allusions were occasionally made to the army hospital question in South Africa But to refer to matters of more or less medical interest we have with regret to record that in the reverse at Tweebosch not only did *Lord Methuen* sustain a gunshot wound of the right thigh attended with compound fracture of the femur, but that Colonel Townsend, R A.M C, who was *principal* medical officer of the force, was wounded in three places after having, it is stated, greatly distinguished himself As it proved he was able to render some effective aid to Lord Methuen subsequently to their capture Both are reported as doing well In the affair at Tweebosch the Boers attacked the British troops with remarkable gallantry and courage *Delarey's subsequent* conduct to his captives seems to have been most humane and *considerate—indeed*, it may be characterised as magnanimous under the circumstances The account of the engagement furnished by the special correspondent of the *Standard*, and published in that journal of March 18th and 19th, is a very clear and graphic description, and it shows that the affair was one of the severest struggles of the war, in which the efforts of the regular *troops might possibly have saved the* situation but for the defection and stampeding of the auxiliaries Be this as it may, we have only to remark that regrettable as such a reverse undoubtedly is at this stage of the war, the force engaged was in reality too small to have any material or lasting effect. It is because it may tend in some degree to protract the operations in the field and consequently to lead to further and needless loss of life on both sides that it is mainly to be *lamented* As regards the prevalence of enteric fever in armies on field service we have so repeatedly called attention to the subject that little or nothing remains to be said A weak part in Mr Brodrick's scheme of army medical reform and reorganisation is in regard to army sanitation It is a matter which requires to be thoroughly gone into from a practical point of view, in order to see if anything can be done to prevent the occurrence of diseases of this class.

### DEATHS IN THE SERVICES.

Surgeon-General Sir William Guyer Hunter, M.D., K.C.M.G., late I.M.S., suddenly on March 15th at his residence at Norwood in his seventy-fourth year. He was educated at King's College, London, and Aberdeen University, and entered the Indian Medical Service in 1850. He served in the second Burmese war and the Indian Mutiny. Among the various offices which he held in India were those of Professor of Medicine in the Grant Medical College, Bombay, and Vice Chancellor of Bombay University. Sir W. Guyer Hunter represented for seven years the borough of Central Hackney in the House of Commons.

Colonel Robert Coleman Eaton, R.A.M.C., at St. Bartholomew's, Spezia, Italy, in his sixty-first year. He entered the service in 1866, and attained the rank of Colonel in 1896. He served in the Afghan war of 1878 and 1880 (medal).

Surgeon General John Robert Theobalds, I.M.S., Madras, aged 79 years. He retired from the service in 1880.

### PROPOSED FRENCH AMBULANCE.

The Paris correspondent of the *Times* states that Vicomte Christian de Villebois-Mareuil has just despatched an official request to the British War Office for authorisation to organise a French ambulance for the Boers and to be allowed to take charge of the ambulance himself.

## Correspondence.

"Audi alteram partem."

## THE MIDWIVES BILL.

*To the Editors of* THE LANCET.

SIRS,—Whatever our views on the subject of legislation to regulate the practice of midwives it is of prime importance that we do not misrepresent the action and the motives of those who differ from us. As one concerned in this controversy and anxious for the real—not spurious—protection of poor lying-in women I shall thank you to insert in THE LANCET the inclosed correspondence which deals with a grave error in Mr. Johnstone's presentation of the subject to Parliament. The responsibility of ignoring conditions insisted on by the General Medical Council is great and not to be minimised by positively erroneous statements. If the tragedies connected with the practice of midwifery by untrained women continue it will not be the General Medical Council that will be to blame.

I am, Sirs, yours faithfully,
Highbury-place, N., March 17th, 1902. JAMES GREY GLOVER.

[INCLOSURE.]

25, Highbury-place, N., March 10th, 1902.

DEAR MR. JOHNSTONE.—In your speech on the Midwives Bill you say that in asking for a penal clause against uncertified women practising for gain the Medical Council was contending for a stepping-stone towards rendering the practice of unqualified medical men absolutely penal (THE LANCET report). Will you allow me with much earnestness and all respect to protest against this statement. I am in a position, though not now in the Council, to say that this statement is absolutely incorrect, and that the clause asking for the penalising of practice by uncertified midwives was urged solely in the interest of lying-in women whose lives are endangered in quite a special way by the practice which it is the object of this legislation to stop.

Of course, all medical men disapprove of irregular and unqualified medical practice, but I think I may challenge you to find in all the records of the General Medical Council a resolution carried by—or even proposed in—that body, asking Parliament to stop unqualified medical practice by penalising it. I need not say that I am no enemy to proper legislation on the subject of midwives. But a measure which omits the principal protection of the poor lying-in women is not legislation but the evasion of it, and is without excuse. At any rate this is the view of the Medical Council in insisting on the clause penalising practice for gain of uncertified midwives, and nothing I am sure is further from your intention than to misrepresent the motives and views of the Medical Council. Poor women do not look at registers and are not guided by titles. So that they will not be protected by merely penalising the use of titles.

Believe me, dear Mr. Johnstone,
Yours very truly,
J. H. Johnstone, Esq., M.P. J. G. GLOVER.

House of Commons, March 12th, 1902.

DEAR DR. GLOVER,—I am very glad to hear from you, on authority, that the General Medical Council do *not* seek to penalise the unqualified practice of medicine, and I hope that by the publication of this correspondence their attitude in this matter may be made clear to the public and to the profession for all time. I owe them an apology if I have, in good faith, misrepresented their aims, but in explanation I may call your attention to the *British Medical Journal* of Feb. 22nd, which in an article dealing with the present Bill states: "It has long been admitted that this omission" (a penal clause) "is a great defect in the Medical Acts, and *to obtain their amendment in this direction every effort should be made.*" However, your letter now makes it clear that the General Medical Council do not wish to penalise the practice of unqualified medical men, while they do wish to penalise the practice of women, of which Sir William Priestley said, and said truly, "it is quite certain that the House of Commons would listen to no such proposal." We have advisedly based our Bill on the principles embodied in the Medical Acts concerning medical practitioners, and beyond that we cannot hope to go at the present time.

Believe me, very truly yours,
J. G. Glover, Esq., M.D. J. H. JOHNSTONE.

*To the Editors of* THE LANCET.

SIRS,—As one of the candidates referred to by Dr. A. McCook Weir in THE LANCET of March 8th, p. 697, as having failed to see that a Nursing Bill was introduced into Parliament at the commencement of the present session I can only plead with regret that during December and January last my state of health was such that I was quite unable to undertake the task of preparing a Bill and getting it introduced into Parliament; indeed, it was only with great difficulty that I could attend to the more pressing of my professional engagements. At my suggestion the council of the Incorporated Medical Practitioners' Association appointed a committee in December to consider the Nursing Bill drafted by Dr. McCook Weir, the suggestions of the Manchester Medical Guild, and the Bill drafted by the Parliamentary Bills Committee of the British Medical Association, but that committee failed to report in time for any action to be taken before Parliament met.

I am, Sirs, yours faithfully,
Gibson-square, N., March 12th, 1902. GEORGE BROWN.

## HIGH FREQUENCY CURRENTS IN THE TREATMENT OF CANCER.

*To the Editors of* THE LANCET.

SIRS,—As an announcement has been recently made that currents of high frequency were about to be tried in the treatment of cancer at one of our London hospitals it is exceedingly probable that medical men who are now in possession of the apparatus necessary to their production will be inclined to do likewise, either in their hospital or private practice. Since I first pointed out this "prospect of cure"[1] at least one other has adopted this treatment, and I am glad to have had a favourable report from him upon its effects in malignant disease. Hence the following remarks, the outcome of six months' experience in this method, may not be amiss. Amongst other preliminary measures the estimation of the percentage of urea should never be neglected. This in cases of cancer is always extraordinarily low (in the last case that has come under my care only 0·46 per cent.), but this improves as treatment continues and gives us useful guidance in the progress of the case.

The treatment is both general and local, and it will be found advantageous to commence with the former by placing the patient within the large solenoid for half an hour daily for the first three days. This is generally called "auto-conduction," but as the currents thus set up within the body are entirely induced, it seems to me that "auto-induction" is the better term. Recourse to this will be had from time to time whenever it is necessary to suspend the local treatment. General treatment can also be applied by auto-condensation, but this method is best used in conjunction with local treatment, which may be either uni-polar or bi-polar. It will be convenient to call that electrode which is on the end of the solenoid which is connected to earth "the kathode," and that which is fixed to the distal end of the solenoid, or resonator (if that is used), "the anode." For auto-condensation the kathode may be a sheet of metal beneath the mattress on the couch; for bi-polar treatment it may be of nickel of a convenient shape for the hand or ending in a plaque either of metal or wet clay when applied to the abdomen at such times as the anode is inserted into the vagina or rectum. The best and most manageable plaque can be improvised from thick lead foil. A similar plaque is a very useful means of applying the anode over any considerable surface; the great point recorded in Glasgow. The deaths from diphtheria, which had been six, one, and seven in the three preceding weeks, declined again last week to six, and included three in Glasgow, where two of the four fatal cases of "fever" were also registered. The deaths referred to diseases of the respiratory organs in these towns, which had been 214 and 230 in the two preceding weeks, declined again last week to 189, but were 18 above the number in the corresponding period of last year. The causes of 13, or nearly 2 per cent., of the deaths in these eight towns last week were not certified.

---

[1] THE LANCET, Sept. 28th, 1901, p. 845.

### *HEALTH OF DUBLIN.*

The death-rate in Dublin, which had been 28·6 and 29·7 per 1000 in the two preceding weeks, declined again to 20·6 per 1000 during the week ending March 15th. During the past four weeks the death-rate has averaged 28·1 per 1000, the rates during the same period being 26·0 in London and 22·3 in Edinburgh. The 150 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 66 from the number in the preceding week, and included eight which were referred to the principal zymotic diseases, against 13 in each of the two preceding weeks; of these, four resulted from measles, two from scarlet fever, one from "fever," and one from diarrhœa. These eight deaths were equal to an annual rate of 1·1 per 1000, the zymotic death-rates during the same period being 3·1 in London and 1·3 in Edinburgh. The fatal cases of measles, which had been three, one, and six in the three preceding weeks, declined again last week to four. The 150 deaths in Dublin last week included 21 of children under one year of age and 37 of persons aged upwards of 60 years, the deaths of infants and of elderly persons were respectively 11 and 38 less than the numbers in the preceding week. No death from violence was registered during the week, two inquests were recorded, and 54, or more than one third, of the deaths occurred in public institutions. The causes of eight, or more than 5 per cent., of the deaths in Dublin last week were not certified.

## THE SERVICES.

### ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Staff Surgeons: G. T. Collingwood to the *President*, additional for service at Deptford Victualling-yard; Charles Strickland to the *Aboukir*, and Hamilton Meikle to the *Vengeance*. Surgeons: Walter P. Dyer to the *Aboukir;* George Gibson to the *Nile;* Harold E. Fryer, Algernon O. Bean, and Warren G. Westcott to the *Hawke*, for duty on the voyage home, and A. J. Wernet to the *Pembroke*, additional, to be lent for service at Deptford Victualling-yard.

### ROYAL ARMY MEDICAL CORPS.

Major T. McCulloch has been appointed Deputy Assistant Director, Army Medical Department, at Headquarters, vice Major W. G. Macpherson.

Colonel J. F. Supple, C.B., has been appointed Principal Medical Officer, Meerut District.

Major D. R. Hamilton has arrived at Colchester. Captain R. S. H. Fuhr is appointed for duty in the Home District. Captain A. R. O'Flaherty is appointed for duty with the 4th Battalion the East Surrey Regiment, ordered to South Africa. Lieutenant H. E. M. Douglas, V.C., D.S.O., is appointed for duty in the Home District.

### INDIA AND THE INDIAN MEDICAL SERVICES.

Colonel A. Scott Reid has been appointed to succeed Surgeon-General Franklin as Inspector-General of Civil Hospitals in the Punjab. Colonel Joubert succeeds Colonel Hutcheson in a similar capacity in the North-West Provinces and Oudh. Colonel Geoffrey Hall succeeds Colonel Scott Reid as Administrative Medical Officer and Sanitary Commissioner in the Central Provinces.

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon Lieutenant-Colonel E. Shedd having resigned his Volunteer appointment, ceases to belong to the Army Medical Reserve of Officers.

### IMPERIAL YEOMANRY.

Surgeon Captain G. H. S. Daniell, of the Dorset (Queen's Own), and Surgeon Captain P. B. Mackay, of the Yorkshire Dragoons (Queen's Own), resign their commissions and receive new commissions subject to the provisions of the Militia and Yeomanry Act, 1901, each retaining his present rank and seniority.

### VOLUNTEER CORPS.

*Royal Engineers*: 1st London: Edward Coldridge Roberts to be Surgeon Lieutenant. *Rifle*: 5th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Captain J. Mill to be Surgeon Major. 1st Volunteer Battalion the Norfolk Regiment: James Morison Gardiner Bremner to be Surgeon Lieutenant. 2nd Volunteer Battalion the Durham Light Infantry: Surgeon Lieutenant R. E. Brown resigns his commission. 5th Volunteer Battalion the Durham Light Infantry: Surgeon Captain A. A. Abraham to be Surgeon-Major.

### SOUTH AFRICAN WAR NOTES.

Civil Surgeon Newton is reported to be improving.

The following officers have been discharged from hospital to duty:—Captain J. D. Alexander, R.A.M.C.; Lieutenant P. S. O'Reilly, R.A.M.C.; Lieutenant R. H. Lloyd, R.A.M.C., Lieutenant J. W. West, R.A.M.C., and Lieutenant C. D. Myles. Civil Surgeons Williams, Dee, Vaux, Jordan, Scott, and Lynch.

### SOUTH AFRICAN AFFAIRS AND THE WAR.

A great deal has taken place, although but little of it has much medical interest or significance, during the brief interval that has elapsed since we last referred to the events of the war. We may shortly enumerate what has occurred. The defeat of the force under General Lord Methuen at Tweebosch with the capture and subsequent release of his lordship who was seriously wounded; the grave and critical condition of Mr. Cecil Rhodes; the increased, if fitful, activity of the Boer forces in the field, the widespread prevalence of enteric fever in South Africa, the improved sanitary state of the refugee camps, the arrival in this country of large batches of sick and wounded officers and men from South Africa; and the embarkation of reinforcements for the seat of war. In addition to the foregoing there has been a debate in Parliament on war contracts involving what would have been a vote of censure on the Government on its conduct of the war had the Opposition succeeded in carrying its resolution. This succinctly summarises the history of recent events which, taken as a whole, have made up a somewhat exciting time. In the course of the late debate in the House of Commons it may be remarked that allusions were occasionally made to the army hospital question in South Africa. But to refer to matters of more or less medical interest we have with regret to record that in the reverse at Tweebosch not only did Lord Methuen sustain a gunshot wound of the right thigh attended with compound fracture of the femur but that Colonel Townsend, R.A.M.C., who was principal medical officer of the force, was wounded in three places after having, it is stated, greatly distinguished himself. As it proved he was able to render some effective aid to Lord Methuen subsequently to their capture. Both are reported as doing well. In the affair at Tweebosch the Boers attacked the British troops with remarkable gallantry and courage. Delarey's subsequent conduct to his captives seems to have been most humane and considerate—indeed, it may be characterised as magnanimous under the circumstances. The account of the engagement furnished by the special correspondent of the *Standard*, and published in that journal of March 18th and 19th, is a very clear and graphic description, and it shows that the affair was one of the severest struggles of the war, in which the efforts of the regular troops might possibly have saved the situation but for the defection and stampeding of the auxiliaries. Be this as it may, we have only to remark that regrettable as such a reverse undoubtedly is at this stage of the war, the force engaged was in reality too small to have any material or lasting effect. It is because it may tend in some degree to protract the operations in the field, and consequently to lead to further and needless loss of life on both sides, that it is mainly to be lamented. As regards the prevalence of enteric fever in armies on field service we have so repeatedly called attention to the subject that little or nothing remains to be said. A weak part in Mr. Brodrick's scheme of army medical reform and reorganisation is in regard to army sanitation. It is a matter which requires to be thoroughly gone into from a and Vice-Presidents was read to the Council at their meeting held this day, and that the Council having heard the same expressed their concurrence in the conclusion arrived at by the Nomination Committee.

I am, dear Sir, yours faithfully,

Jan. 16th, 1902. S. FORREST COWELL, Secretary R.C.S.

Having received this official decision I called upon the author of the letter to withdraw his statement, and under the pressure of an action at law he has now done so and given me an ample apology in writing. I should not trouble you, but that the slander having been widely spread I shall be obliged by your assistance in spreading equally widely the refutation of it. I have placed the apology in the hands of the President of the Royal College of Surgeons of England. I am, Sirs, yours faithfully,

W. D. HALLIBURTON.

King's College, London, March 15th, 1902.

## GREY HAIR AND EMOTIONAL STATES.

*To the Editors of* THE LANCET.

SIRS,—I trust that you will allow me to add a supplementary note to my letter on the above subject (published in THE LANCET of March 8th, p. 696) for the purpose of drawing attention to a remarkable case of hair-blanching which is in danger of being overlooked. The case is one incidentally referred to by Sir W. R. Gowers in his lecture on Metallic Poisoning (published in THE LANCET of Nov. 2nd, 1901, p. 1173). A man received a blow on the head which resulted in an effusion of blood over the left hemisphere, death occurring after three days. This injury so disturbed the innervation of the hair follicles of the right side of the moustache and beard that the hair in this region, which was brown, gradually became blanched and at the time of death was almost white. This was sufficiently remarkable, but what made the case more remarkable still was the fact that the blanched hair of the right side was separated from the normal brown hair on the left side by a narrow median zone of almost black hair, as though the pigment abstracted from the blanched area had become deposited in this darkened zone. Sir W. R. Gowers would, I presume, infer from this case that the nutrition of the hair follicles on one side of the body is under the control of the opposite cerebral cortex.

I am, Sirs, yours faithfully,

Wimpole-street, W., March 16th, 1902. HARRY CAMPBELL.

## THE SUBJUGATION OF SMALL-POX.

*To the Editors of* THE LANCET.

SIRS,—I have been looking over your article in THE LANCET of the 8th inst., headed "The Subjugation of Small-pox," and I find that some of the passages therein relating to vaccination are utterly ridiculous and I cannot understand how it is that they have made their appearance in the columns of such a journal as THE LANCET. The only conclusion that I can arrive at is that they have been made by a party who probably knows nothing of the history of vaccination. The statistics and experiences with vaccination, which have been recorded since the practice became general, go to show that vaccination has not only been useless but it has proved harmful, even to the extent of causing several deaths. I see in your issue it is stated: "Every individual human being carries within himself the soil in which the germs of disease may be implanted. The soil must be made unfit for such noxious growth, and this, in essence, is what vaccination does." This statement is really very absurd, as I can myself quote cases where parties have been vaccinated and caught small-pox and *died* with it, from any time directly after the vaccination. Also, cases where parties have been vaccinated as many as six or seven times and eventually died of small-pox. Also, cases where persons have been vaccinated several times and had small-pox more than once or twice and eventually died of it.

If, as THE LANCET states, vaccination makes the human system unfit for the development of small-pox, how is it that it is possible to have cow-pox first, and catch small-pox and have them at one and the same time hand in hand with the result that the attack of small-pox proves the victor by a fatal termination? It is also stated that "every person has it in his power to render himself *safe* from an attack of small-pox." If this is so, I would be greatly obliged if you would let me know how it can be done, as I for one must confess that beyond the fact of studying the laws of health and living cleanly I am ignorant of any preventive measures having ever been introduced whereby a person may render himself immune from this filthy disease, or even modify it. You conclude: "The epidemic wave will pass in time, but very much can be done to check its career and to diminish its intensity by the general adoption of a practice of which the efficacy has been proved by the experience of all civilised nations during the century that has elapsed since its introduction."

I am not aware that anything has been *proved* as yet with regard to the benefit that vaccination has been, and I feel sure nobody else is. The practice is based upon a superstition put forward by an ignorant set of milkmaids and is not based upon any scientific foundation, and was boomed by an unscrupulous person—i.e., Edward Jenner—who purchased his M.D. for £15, and, as history informs us, he knew all the time that his "discovery" (which, by the way, was not his at all) was a complete fraud. There is a great mass of information on this subject which, if people would only give to it their unanimous attention, I feel sure that vaccination and all its evil effects would be a thing of the past.

I trust you will not find I am writing too lengthily, but I feel, after what I have learned, that I could not resist the temptation of writing you on the matter appearing in your journal.

I beg to remain, yours respectfully,

Tottenham, March 13th, 1902. A. J. WHITEHEAD.

⁂ We think it well to publish this effusion, for our readers seldom have the opportunity of reading such statements.—ED. L.

## THE NAVAL ESTIMATES.

*To the Editors of* THE LANCET.

SIRS,—At page 760 of your issue of March 15th you rightly ask why deputy inspectors-general of the Royal Navy receive no increase of pay while every other class of medical officer has been so dealt with. The explanation is that the naval authorities have followed in the main the recommendations of the Army Advisory Board on the pay of the Royal Army Medical Corps. This latter board, in a stupid way, excluded the colonel's rank in the Royal Army Medical Corps from any increase of pay, although it was as urgently needed for them—indeed, more so than in the case of most medical officers. These officers are principal medical officers of districts and have much responsibility, yet in a few weeks when the warrant is issued they will receive *less annual pay* than senior lieutenant-colonels in charge of hospitals serving under their command. Further, with reference to the pay of R.A.M.C. colonels, by comparison with other colonels on the staff of the army please note the absurd position which now exists. Colonels on the staff for infantry and Royal Artillery, annual pay, £980 18*s.* 5½*d.*; colonels on the staff for Royal Engineers, £1163 8*s.* 5½*d.*; colonels on the staff, R.A.M.C., £947 9*s.* 3*d.* Could anything be more absurd? What is needed is an increase of 10*s* per diem both to colonels R.A.M.C. and deputy inspectors-general of hospitals. This is absolutely needed for those important classes of officers.

I am, Sirs, yours faithfully,

March 17th, 1902. I.V.R.O

## SOCIETY OF LICENTIATES AND MEMBERS OF THE LONDON ROYAL COLLEGES.

*To the Editors of* THE LANCET.

SIRS,—Why on earth the holders of the Conjoint M.R.C.S., L.R.C.P., should petition for the right to a gratuitous degree any more than any other qualified practitioners puzzles me greatly. A person holding the L.S.A. Lond., L.A.H. Dub., L.R.C.P., L.R.C.S., L.F.P.S., or M.R.C.S. has surely an equal right to an honorary M.D. I certainly think that every qualified man should be allowed this privilege. But if there is to be a gift of this sort all qualified practitioners must share alike. I am, Sirs, yours faithfully,

March 17th, 1902. JUSTITIA.

is to make it fit so closely that no sparking takes place on to the patient. In other cases the anode may be of the ordinary cylindrical shape. For cavities—vagina, rectum, &c.—the most efficacious form of anode is that of a highly-exhausted glass cylinder, of a size suited to the locality, provided with a single pole; this gives good efflorescence and is quite harmless when used with d'Arsonval's apparatus or Oudin's resonator. It is of importance that the skin around the orifices should be well dried and even powdered with starch before inserting the electrode, as a precaution against the spark jumping from the electrode on to the moist skin; also, the electrode should be in position before the current is turned on. The local application will be needed for from 10 to 20 minutes. For broken surfaces the best results are first obtained by the anodic spray.

Any improvement must necessarily be slow and too much must not be expected at first. The earliest signs will be shown in the general condition, in the cessation of pain, the lessening of the cachectic appearance, the increase of urea, the renewed vigour, and interest in life. How far these results will be permanent is as yet too early to decide, and I think that it would be wise not to estimate a case as cured until some considerable time has elapsed. We must not be disappointed if very little change is found in the size of the cancerous masses. They appear to shrink somewhat and this I take to be due to the cessation of action in the growing edge. Apostoli has remarked that in the electric treatment of uterine fibroids, devised by him, the tumours do not disappear although they cease to grow and give no further trouble to the patient. Quite recently it has been shown that several tumours which have been treated in this manner have become polypoid and have come within the reach of easy removal. The treatment by high frequency currents has the advantage of being painless and easy of application.

I am, Sirs, yours faithfully,
HORACE MANDERS.
Bentinck street, March 15th, 1902.

## THE DISSEMINATION OF KNOWLEDGE CONCERNING VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—I was unaware that the Jenner Society is taking steps for giving popular lectures on vaccination. I feel sure that they will be useful. It is possible that anti-vaccinationists will attend to challenge the facts, and for such contingencies the lecturer ought to be prepared. Lectures, illustrated by lantern slides, on "The Germs of Disease" would probably be well received. The bacillus tuberculosis, bacillus diphtheriæ, and bacillus typhosus could be shown, and interesting facts mentioned as to their mode of growth, manner of infection, and the proper steps to be taken for their destruction. Small-pox and vaccinia can be illustrated by slides exhibiting the germs identified by Klein and other observers as peculiar to these affections, and, as already suggested by me, coloured slides could also be used to prove what a case of genuine small-pox really is.

I hope that by such methods those that "came to scoff" might be induced to be vaccinated; and the society of which Dr. F. T. Bond is the honorary secretary will no doubt do most valuable work in furthering this good cause.

I am, Sirs, yours faithfully,
HERBERT W. G. MACLEOD, M.D. Edin., D.P.H. Cantab.
Streatham, S.W., March 11th, 1902.

## CANCER IN INDIA AND IN CHINA.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of Jan. 18th, p. 192, Mr. C. B. Keetley inquires in the course of his letter on the subject of cancer whether Mahomedans practise circumcision or not. Possibly long before this letter can reach you some one else will have given Mr. Keetley the information which he seeks, but in case no other person has supplied the want I beg to bring forward the following note on the subject. The subject is an interesting one, and the facts regarding it cannot very well be condensed without obscurity, so that I must apologise if my communication is rather lengthy.

All Mahomedans practise circumcision, though there is absolutely no reference to the rite in the Koran. There is also no authentic account of the circumcision of the Prophet Mahomed himself, but certain authors assert that he was born circumcised. This allegation is, however, denied by the most eminent scholars. The rite is held to be *Sunnah*—that is to say, founded upon the practice of the Prophet. It is directed to be performed between the ages of seven and 14 years, though it is stated in the Sahih ul Bukhāri that Abraham was circumcised at the age of 80 years with an axe. He is further said to have been the first to have received the injunction to submit himself to the rite, which is there stated to be one of the five duties appertaining to *Fitrah* or observance of the acts of the Prophet, the others being shaving of the pubes, plucking the hair from the armpits, clipping the beard and whiskers, and paring the nails. It is clear from this association that circumcision (*Khitān*) was regarded as purificatory rather than ceremonial. An account of the ceremonies attending the rite of circumcision among Moslems will be found at page 30 of Herklots, "On the Manners and Customs of Muhammadans of India." Consult also Hughes, "Dictionary of Islām," article "Circumcision." I hope that this note may be of some service to Mr. Keetley.

I am, Sirs, yours faithfully,
GEORGE S. A. RANKING, M.D. Cantab.,
Lieutenant-Colonel, I.M.S.
Calcutta, Feb. 26th, 1902.

*To the Editors of* THE LANCET.

SIRS,—I regret to see from Mr. C. B. Keetley's letter in THE LANCET of Jan. 18th, p. 192, that he has taken umbrage at my attempt to assist him in his inquiries regarding cancer. My desire was to point out what I believe to be a misapprehension regarding the comparative immunity of Hindoos to cancer. To say, as Mr. Keetley does, that I alone am responsible for all the medical and surgical wants of 30,000,000 Hindoos in Southern India is as absurd as it would be to say that Mr. Keetley was responsible for the whole population of London. I have only 90 beds under my charge, the average daily sick occupying those beds being something under that number. These are all males and all surgical cases. Amongst this small number of cases I almost always have one or two Hindoos suffering from cancer, and this fact is, as I stated in my former letter, strong evidence to the effect that cancer is common amongst these people. My belief is shared by every medical man, both native and European, with whom I have conversed upon the subject. I regret for Mr. Keetley's sake that I am unable to give any statistics regarding the question, but my colleague, Captain W. J. Niblock, is at present engaged in collecting information of this nature and no doubt will publish the results of his investigation. The answer to Mr. Keetley's query regarding circumcision is that all Mahomedans undergo this rite. It is as obligatory upon the Mahomedan as baptism is upon the orthodox Christian.

I am, Sirs, yours faithfully,
J. MAITLAND, M.D. Edin.,
Lieutenant-Colonel, I.M.S.
General Hospital, Madras, Feb. 2[illegible]th, 1902.

## THE NOVEMBER PRIMARY F.R.C.S. ENG. EXAMINATION.

*To the Editors of* THE LANCET.

SIRS,—Shortly after the primary Fellowship examination last November I was informed that a slanderous rumour was being actively propagated to the effect that I had prematurely divulged to the members of my class the nature of the questions which had been set for the written part of that examination. This slander was set in motion by a letter written by a medical practitioner to a demonstrator of physiology in one of the London medical schools. The writer was an entire stranger to me. The letter was, without my knowledge, passed on to the President of the Royal College of Surgeons of England who summoned a meeting to consider the matter. I was invited to be present at this meeting. The result of the inquiry will be gathered from the following letter which I subsequently received from the Secretary of the College:—

DEAR SIR,—I am directed to inform you that at a meeting of the Nomination Committee on Dec. [illegible] the following resolution was adopted—viz.: That the evidence taken by the President and Vice-President [illegible] submitted to the Council [illegible] that the Council be informed that after careful consideration of [illegible] Committee conclude that there is no evidence that Dr. Hal[illegible] either intentionally or unintentionally supplied information on the subject of the questions at the last Primary Fellowship examination."

I am to add that a report of the evidence given before the President workhouse hospitals have had such happy results, died at his residence at Greenbank on March 6th at the ripe age of 83 years. The late Mr. Rathbone was also instrumental in the establishment of the training home in Ashton-street in 1860, which was to provide professional nurses for the Royal Infirmary in the first instance; secondly, district nurses for the poor; and thirdly, sick nurses for private families. Within four years from the date of this new and interesting departure Liverpool was divided into 18 districts, each under the management of a lady superintendent with a nursing staff. At first the nurses lived in lodgings, but it was one of Mr. Rathbone's aims that there should be permanent district nurses' homes. Another object of his desire was to render the movement not merely local but national. In both these respects his efforts were crowned with success. The example set by Liverpool was first profited by in London, where, in 1868, Mrs. Stuart Wortley founded the East London Nursing Society. The Metropolitan and National Nursing Association was shortly afterwards established. The initiative was taken by the Council of the Order of St. John of Jerusalem, the chief promoters being Lady Strangford, Mr. William Rathbone, Sir H. W. Acland, Sir Edmond Lechmere, and Sir Robert Wigram. The object of the association was to train a body of skilled nurses to nurse the sick poor in their own homes and to establish associations for that purpose in London and throughout the country. The training home was established in connexion with St. Katherine's Hospital. In 1890 the Queen Victoria Jubilee Institute, as it was then named, was incorporated by Royal Charter. Mr. Rathbone was appointed one of the vice-presidents. District associations were established in many of the chief towns of the kingdom, the Liverpool association being affiliated with the Jubilee Institute. Through Mr. Rathbone's advocacy the fund raised in Liverpool in celebration of the late Queen's Diamond Jubilee was devoted to this charity and was applied to the provision of district homes. Mr. Rathbone, in the face of great difficulties and opposition on the part of the Select Vestry of the Parish of Liverpool, of which he was a member for 40 years, succeeded in reforming the manner in which the sick poor were nursed at the Liverpool Workhouse in the year 1868. The nursing which was carried out by paupers was a mere farce. In his enthusiasm to reform the lamentable treatment of the sick there he undertook to bear the whole of the additional expense of the new system for a term of three years. He brought down a staff of nurses trained at the Florence Nightingale School at St. Thomas's Hospital. The late Miss Agnes Jones, an experienced lady, also from St. Thomas's Hospital, was intrusted with the superintendence of this staff After two years' trial of the reformed system, which worked out admirably, the Select Vestry had no alternative but to adopt it. To revert to the old system was out of the question. Birmingham and Manchester soon followed in the wake of Liverpool in reforming the nursing arrangements of their workhouses. The following resolution was unanimously carried at the recent meeting of the committee of the Royal Infirmary :—

> The committee desire to place on record their deep sense of the loss they and the Royal Infirmary have suffered by the death of Mr. William Rathbone. Mr. Rathbone was the senior member of the committee, having been elected in 1860, and had always taken the warmest interest in the welfare of the institution, more especially in that part of the work connected with nursing. To Mr. Rathbone the committee are indebted for the nurses' home which he built entirely at his own expense and presented in 1862 and which has proved itself of inestimable value In the building of the new infirmary Mr. Rathbone took a most active part and by his death the institution has lost a friend it can ill afford to lose and the committee a colleague for whom they had the highest regard and esteem.

### *West Derby Guardians: a Costly Lunatic.*

At the last meeting of the West Derby Board of Guardians it was reported that an inmate of the Rainhill Lunatic Asylum whose maintenance was chargeable to the West Derby Union had died on March 6th. The patient had cost the union close upon £900, having been an inmate of Rainhill Asylum since 1862.

### *Ladies' Charity and Lying-in Hospital: the School of Midwifery.*

The report of the board of management of this institution states that the out-door patients during 1901 numbered 1554, as against 1523 in the previous year. By the removal of pupils to the "home" the number of beds for patients had been increased to 20, and 218 patients had been admitted (against 204 in 1900), of whom 18 were unmarried girls. There were three deaths in the hospital and three in the out-door department. A ward had been specially fitted up for the treatment of difficult cases. In the school of midwifery 39 pupils were trained, of whom 29 received certificates; 22 monthly nurses were trained by the matron; and 18 medical students took out their course of practical midwifery in the out-door department. Mr. Walter Clark had given £400 for investment, being impressed with the serious condition of the finances. The debit balance now amounts to £430.

### *The Medical Officer of Health on the Value of Revaccination: Interesting Facts.*

At the recent meeting of the Health Committee, Dr. E. W. Hope (the medical officer of health) related to the committee an interesting incident in connexion with vaccination. A certain lodging-house had been temporarily closed and all the inmates who would submit to it were revaccinated. 71 lodgers and 14 of the servants were revaccinated. 13 lodgers, however, refused absolutely to be revaccinated. It was a remarkable and significant fact that none of the 71 lodgers or the 14 servants who were revaccinated took small-pox; but out of the 13 lodgers who refused the operation nine had already developed the disease. But the serious point in the matter was that nine people who were ultimately removed to hospital with small-pox had been roaming about here, there, and everywhere before they could be got hold of and in that way a considerable amount of mischief might have been done.

### *The New Parish Infirmary.*

The erection of the new infirmary for the parish of Liverpool, which the Select Vestry has had in contemplation for some time past, will shortly take place. A tender of £74,650 for the purpose has been accepted.

March 18th.

## WALES AND WESTERN COUNTIES.

(From our own Correspondents.)

### *Rhondda Isolation Hospital.*

A well-equipped isolation hospital was formally opened in the Rhondda Valley on March 13th. There is accommodation in two ward pavilions and an observation block for 36 patients and the population served is about 120,000. The entire cost of the land, buildings, and furnishing was nearly £15,000, and this sum has been paid out of the current rate of the district, so that the institution has been completed without any interference from the Local Government Board, though the recommendations of the Board have in all essential particulars been adopted. The general arrangement of the buildings follows the lines usually adopted in the erection of a fever hospital but differs in some important points of detail. For example, in every bedroom, whether occupied by nurse or servant, there is a fixed lavatory basin with hot and cold water laid on—a luxury which is not so extravagant as at first sight it would appear to be, for not only is there saved the first cost of washhandstands, &c., but there is no current charge for broken jugs and basins. In the pavilions the single bed wards, although overlooked by observation windows from the nurse's duty room, can be completely cut off from the large wards and can be entered by a separate lobby from the outside. The entire flooring in one pavilion is of terrazzo. The type of slop-closet is an excellent one, and is so contrived that a bed-pan is placed in a rounded cupboard closed in with a tightly-fitting glass door, and the contents of the pan can be kept in contact with a disinfectant for any length of time and finally discharged into the soil-pipe. The pan is completely cleaned out without any risk of contaminating surrounding surfaces or of splashing the ward-maid. The inlet ventilators at the floor level are adapted for cleaning from the inside and the cavity in the walls is lined with glazed tiles to facilitate the wiping of the interior, thus preventing that accumulation of dirt which always takes place when the gratings both on the outside and inside are made immoveable.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*Great Increase of the Plague Epidemic.—The Continued Famine.—Density of Population and One-roomed Tenements —Medical Appointments.*

THE outbreak of plague shows an increase in nearly every province of India. For the week ending Feb. 8th there were 15,165 deaths from plague, as against 12,192 for the previous seven days and 4377 in the corresponding week of 1901. The Bombay Presidency returns 4676 deaths; Bombay city, 549; Karachi, 44; the Madras Presidency, 562; Mysore State, 576; the Bengal Presidency, 953; Calcutta, 124; the North-West Provinces, 1526; the Punjab, 5529; Kashmir, 479; and the Hyderabad State, 146. As I forecasted, there are a great increase in Bombay city and the Punjab and a marked development in Calcutta and the North-West Provinces.

It is not generally noticed that the famine increases rather than diminishes. There are now 280,000 people under relief and there was an increase of 50,000 during the past week In consequence of the failure of the winter rains in the Punjab the Bombay Government estimated its famine expenditure during the coming financial year at 45 lakhs of rupees.

The percentage of the population occupying one-roomed tenements in Indian cities is enormous and it indicates the widespread poverty of the people. For comparison I will take London with 18 per cent. of tenements as one-roomed; Stockholm, 49 5; Berlin, 44, and Christiania, 37. Bombay has no less than 87 25 per cent. of the total tenements one-roomed, and it is estimated that about 80 per cent. of the population reside in tenements of one room, the average number of occupants to each tenement being between four and five. Compare, again, Leeds with 1·3 per cent. of tenements one-roomed; Gateshead, 10 2; Stockport, 1, and Southampton, 6 2. It was stated by the Registrar-General of England that overcrowding may be said to exist where the average number of persons per room is more than two. In Bombay city it is between four and five. To complete the percentage there are only 6 54 per cent of two-roomed tenements and 2 36 per cent. of three roomed tenements in Bombay, the remainder being a little more than 1 per cent. Take, again, the respective populations living under these conditions. In London 9 4 per cent. occupy one-room tenements, whereas in Bombay city it is about 80 per cent. In certain districts of the city the overcrowding and poverty are extreme. In the district of Dongri 95 per cent. of the population are in single rooms and seven other districts have over 90 per cent. living under similar conditions. The district of Kumbharwada has 598 persons to the acre, that of 2nd Nagpada 546, and that of Khara Talao 556. It is difficult to realise what these figures actually mean without a visit to these places.

Mr. J Nield Cook has been reappointed for a term of three years as health officer of Calcutta.—Colonel A. Scott Reid, I.M.S, has been appointed to succeed Surgeon-General Franklin as Inspector General of Civil Hospitals, Punjab, and Colonel Jubert succeeds Colonel Hutcheson similarly in the North-West Provinces.

14th.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *The Birmingham General Hospital.*

THE 122nd annual report of the hospital just presented at a meeting of governors gives some interesting details. It states that the final reports and accounts of the building committee have been adopted, and that the old building, which was sold to the corporation, has been pulled down after an existence of some 130 years. A portrait of Sir John Holder, presented by 208 governors, has been added to the valuable portraits already adorning the walls as a memento of one of the greatest benefactors of the hospital. A sum of £5131 odd was received from the Hospital Sunday Fund Committee, and the amount of £3100 from the Hospital Saturday collections Under a recent new law six lady governors were appointed as lady visitors; two of these visit together in rotation, arrangements being made for special attention being given to the female wards and the nurses' and the servants' quarters. The board of management expresses great satisfaction at the receipt of four sums of £1250 each for the dedication of four more beds in the hospital. It is contemplated to appoint an honorary officer to take charge of the ear and throat department alone, and some further modification in the rearrangement and payment of the resident medical officers is proposed. The number of in-patients during the year was 5170 and of out-patients 62,643 or 1778 more than in the previous year. The ordinary expenditure was £24,411, an adverse balance of over £5000 remaining at the end of the year. The report of the Jaffray Branch was also submitted at the same meeting when it was shown that the income for the year was £2471 and the expenditure £2522. During the year 233 patients have been treated, the average length of stay being 14 weeks In this branch there are 10 beds, each of which has been endowed at a cost of £1250, and the committee wisely draws attention to them as a suitable means of perpetuating the memory of relatives or friends.

### *Queen's Hospital, Birmingham.*

The committee, in the sixty-first annual report, calls attention to certain figures which state the income to have been during the year £9606 and the expenditure £11,258; the number of in-patients has been 2189 and that of out-patients 28,895. The amount of £2000 was received from the Hospital Saturday collection during the year. Various other handsome amounts have also been received. A system of internal telephonic communication has been installed and a register of nurses for private cases has been established. Nurses who have completed four years' training and have obtained their certificates are eligible to have their names placed on the register. New residences for nurses and servants are about to be erected and in various directions improvements are to be carried out which will greatly facilitate the working details of the administration.

### *Birmingham Medical Institute.*

The annual report, to be presented on March 25th, states that there are 202 members; during the past year 13 have resigned and 15 have joined. The committee speaks regretfully of the heavy loss sustained annually by arrears of subscriptions and recommend more decisive steps to be taken to secure a prompter payment of these. The revenue account for the year shows the expenditure as £472 15*s*., the balance of excess of income over expenditure being £13 18*s*. 10*d* The committee recommends that all dentists on the Dentists Register shall be eligible for admission. It also recommends that such persons (other than those on the Medical, Dental, and Veterinary Registers) whom the committee may consider entitled by virtue of their office or profession to such privileges may be admitted as subscribers.

March 18th.

## LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

### *Formal Opening of the David Lewis Northern Hospital by the Princess Louise (Duchess of Argyll).*

THE Princess Louise, who was accompanied by her husband, the Duke of Argyll, formally opened the David Lewis Northern Hospital on March 13th. The ceremony was performed in a specially erected pavilion in the grounds of the hospital which accommodated 1400 people. Her Royal Highness was presented with a handsome gold key as a memento of the occasion. The new hospital contains 220 beds and has cost £120,000 This large sum, as stated in a former issue of THE LANCET, has been provided by the David Lewis trustees (Mr Benn Wolfe Levy and Mr. George J. Cohen). Purses were presented to the Princess, containing £1605, in response to the appeal of the committee on behalf of the Sustentation Fund. The whole cost of the opening ceremony was generously defrayed by Mr. Benn Levy, which is only one of the many generous gifts bestowed by him upon the hospital

### *Death of a Liverpool Philanthropist: Tribute by the Committee of the Royal Infirmary.*

Mr. William Rathbone, formerly M.P. for Liverpool, whose efforts to reform the system of nursing formerly in vogue in seem to the court to be inadequate they propose that the salaries should all be raised to £350, the fees to be paid into the fee fund. The sum required for this would be an annual grant of between £2500 and £2800. The scheme of university extension lectures could be reorganised provided the University had sufficient funds for the purpose. This scheme was at one time in existence, but failed solely on account of want of funds. Post-graduate lectureships and scholarships are much needed and would be of the greatest value to the university. It would also be desirable to increase the annual class grants which are made to the scientific and medical classes and which are spent by the professors on apparatus and on perishable materials used in the classes. The University has at present no means at its disposal to increase those grants. Additional assistance is also required by some of the professors. The need of additional accommodation for the library is urgent, and the grant for books has long been felt to be insufficient.

### *Dundee College.*

In the case of the Dundee College the necessity for medical buildings is very urgent. Five new chairs and one permanent lectureship in the Faculty of Medicine of the University of St. Andrews were founded in 1898 with the condition that the work should be carried on in University College, Dundee, and in addition several lecturers were appointed by the University Court. For those new departments temporary accommodation had to be made, as there was no adequate accommodation in the existing buildings. Plans and specifications for a new building have been drawn out and tenders for the work have been received. For the whole work involved in building and equipping the School of Medicine the cost may be summarised as follows: for buildings and fittings, a sum of £6000; for equipment, a sum of £5000. Reconstruction of the existing buildings is also much needed, and it is hoped that this may be shortly carried out at a cost of from £30,000 to £40,000. A scheme spreading the expenditure over seven years is suggested, the items of capital expenditure being as follows: medical buildings, fittings, and equipment, £11,000; chemistry extension, building, and equipment, £3000; engineering extension and equipment, electrical engineering, &c., £42,800; botany, £500; zoology, £500; geology, £500; library, £1000; total, £66,100. In addition to this annual grants are desired for the maintenance of laboratories and museums, as well as for books and periodicals. The most urgent needs of the University of St. Andrews may therefore be summarised as follows—viz.: 1. (*a*) St. Andrews.—The alteration of the present buildings and the erection of additional new buildings, including laboratories of research for chemistry and physics. (*b*) Dundee.—The erection and completion of the medical buildings. 2. The provision of additional accommodation for the University library in St. Andrews and a larger annual sum for expenditure on books and scientific journals. 3. A lectureship in German. 4. A lectureship in geology.

March 19th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The National Hospital for Consumption.*

THE annual meeting of the supporters of the National Hospital for Consumption, Newcastle, co. Wicklow, was held on March 14th in the hall of the Royal College of Physicians of Ireland. His Excellency the Lord Lieutenant of Ireland honoured the meeting by his presence, and in proposing the adoption of the report he delivered a most interesting speech in which he alluded to a former meeting in that hall over which he had presided and at which the question of tuberculosis was discussed in reference to the congress which had since taken place in London and which had been initiated by His Majesty the King. The President of the Royal College of Physicians of Ireland, Sir Christopher Nixon, seconded the motion and stated that he looked upon it as a matter of regret that His Most Gracious Majesty had seen fit to abandon his visit to Ireland, as he would have got not only a warm but an enthusiastic reception in that country. Referring to the very favourable statistics contained in the hospital report, he said that he took a deep interest in the proposed sanatorium for the consumptive poor of the north side of Dublin, in connexion with which a special inducement would soon be offered to which the general public and the corporation itself would find it very hard to refuse support. In reply to a vote of thanks to His Excellency, proposed by Dr. J. Magee Finny, the Lord Lieutenant said, in allusion to the remarks of the President of the Royal College of Physicians of Ireland, that nobody regretted the abandonment of the King's visit more than he did, and he added that he would go further and say that nobody would share that regret more than His Majesty himself, with whom the idea of the visit had originated.

### *Notification of Infectious Disease in Dublin.*

After a very long delay the Urban District Council of Blackrock has decided to adopt the Notification of Diseases Act, 1889, and the Prevention of Diseases Act, 1900, in the township. On March 11th Mr. D. E. Flinn, the Local Government Board medical inspector, addressed the councillors of Kingstown and endeavoured to induce them to adopt the same measure. In that case the matter was referred to a committee for further consideration and it will therefore be probably delayed much longer. It seems a misfortune that these Acts, which are compulsory in England, should still continue to be only voluntary here.

### *Small-pox in Belfast.*

On March 13th a man who had been arrested in Govan (Glasgow) on a charge of bigamy and had been brought over to the county gaol in Belfast developed signs of small-pox, which he had contracted in Glasgow, and was immediately removed from the prison to the Belfast Union Infirmary. The attack is, so far, a mild one.

### *Death of Mr. James Tomb, M.D., M.Ch.R.U.I.*

I regret to announce the death of Dr. James Tomb which occurred on March 13th at his residence in Crumlin-road, Belfast, after an illness of a few days, from pneumonia secondary to influenza. After studying at Belfast Dr Tomb graduated M.D. of the Royal University in 1887. For a time he acted as assistant to Dr. Stewart of Portadown (one of whose daughters he married). Subsequently he settled in the north end of Belfast, where, by the utmost attention to, and care of, his patients, he developed a large working-class practice. He leaves a widow and two children. Dr. Tomb was only 41 years of age. He was buried in Belfast on the afternoon of March 15th, an immense number of friends attending the funeral.

### *The Lisburn Workhouse.*

The inspector of the Local Government Board reports in reference to his official visit to the workhouse at Lisburn on Feb. 5th and 6th that while that institution affords sufficient accommodation as to size, it does not do so in regard to internal arrangement. Separate wards for consumption and for specific disease have not yet been provided in the infirmary, and there are neither day-rooms for convalescent patients nor an operating table. The infirmary in respect of size is not adequate to the wants of the union. The inspector suggests that the vacant auxiliary hospital at the front of the workhouse should be used for the accommodation of consumptive and convalescent patients. He recommends that the guardians should send samples of milk and butter for analysis and that modern grates (to prevent waste of coal) should be provided. He hopes that the drainage of the workhouse will receive attention and that a vehicle will be provided to bring patients to the fever hospital. The inspector considers the windows to be totally unfit for a hospital and he recommends the gradual introduction of a new type of beds. He points out that the infirmary floors are in bad order. Altogether the Lisburn guardians have a good deal of work before them if they make the necessary reforms suggested in this report.

March 18th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

### *An Election Circular.*

WITHIN a few weeks a general election will be held throughout France. Preparations for the struggle have already begun and committees are being formed to support

### *The Prevention of Spitting.*

The Public Health Acts do not appear to give any power to sanitary authorities to frame by-laws for the prevention of spitting in public places, and an attempt has been made by at least one corporation—that of Liverpool—to obtain the power by means of a private Bill. Under the Local Government Act, 1888, however, a county council may make by-laws for "the good rule and government of their county" and such by-laws are not subject to the approval of any higher authority, but merely come into force 40 days after they have been sent to a Secretary of State. The Glamorganshire County Council in the exercise of this power has passed a by-law which reads thus: "A person shall not spit on the floor of any public carriage, or of any church, chapel, public hall, waiting-room, schoolroom, theatre, or shop, whether admission thereto be obtained upon payment or not." There is a maximum penalty of £5 for offending against the by-law. The Sanitary Committee of the Monmouthshire County Council will suggest at the next meeting of the council a similar by-law for Monmouthshire. If these by-laws are not held by the courts to be *ultra vires* it will be found that the powers of county councils are not so restricted as was at one time supposed.

### *A Coroner and the Home Office.*

On Saturday, March 1st, a girl employed at the Aberdare Tinplate Works lost her life by falling into a tank of vitriol. Such an accident is one more than any other which ought to be inquired into by one of His Majesty's inspectors of factories. It is to be deplored, therefore, that at the inquest which was held on the following Monday the coroner should have refused to adjourn the inquiry in order to enable the factory inspector to visit the scene of the accident. Section 21 of the Factory and Workshop Act, 1901, provides that the coroner need not adjourn an inquest held in connexion with the death of a person caused by an accident in a factory or workshop if he has sent to the factory inspector a notice of the inquest to reach him not less than 24 hours before the holding of the inquest and if the majority of the jury think it unnecessary to adjourn. The coroner in this instance does not appear to have been familiar with this section of the Act and the Home Secretary, upon being questioned in the House of Commons on March 13th, gave it as his opinion that a notice received at an inspector's office on Sunday of an inquest to be held on Monday is not a proper notice as required by the Factory and Workshop Act, and he added that the coroner's refusal to adjourn the inquest appears to have prevented the jury from having all the facts of the case brought before them.

### *Risca Health Report.*

The annual report of the medical officer of health (Dr N. Cullinan) upon the sanitary condition of Risca, a mining district of Monmouthshire, is not very satisfactory reading. The death-rate in 1901 was 20 per 1000, and for the previous 10 years it was 17·7 per 1000. Polluted water-supplies, insufficient means of sewage disposal, lack of isolation accommodation, and overcrowding of houses all appear to contribute to the high death-rate.

### *Bristol Medical Mission.*

The annual meeting of the friends of this mission was held on March 13th, under the presidency of the Lord Mayor of Bristol. The medical report stated that 7895 patients had been treated during 1901, including 1994 who were attended at their homes, 25,936 visits being paid. The financial statement was satisfactory, and it showed that the unfavourable balance of £372 with which the year commenced had been reduced to £30.

### *Sanatoriums for Phthisical Patients.*

A county meeting was held at Dorchester on March 11th, under the presidency of Lord Ilchester, for the purpose of considering whether Dorsetshire should establish a separate sanatorium for phthisical patients or should combine with Devonshire and Cornwall in the erection and maintenance of such a sanatorium. On the proposition of Lord Portman, seconded by Lord Stalbridge, a committee was appointed to consider the question. The general feeling of the meeting was apparently in favour of a joint sanatorium for the three counties.

March 17th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The Examination of Pathological Products in Edinburgh.*

IN THE LANCET of March 1st, p. 622, reference was made to this matter. At that time the Public Health Committee of the Edinburgh Town Council had decided that no arrangement for the performance of this kind of work could be regarded as final and satisfactory which did not provide for its being done by the public health authorities, and that in view of this the present arrangement with the Royal College of Physicians should be continued. When this recommendation of the Public Health Committee came up before the town council it was debated and rejected, the council deciding that the work should be transferred to the Usher Institute of Public Health attached to the University. Following upon this a meeting of the members of the medical profession in Edinburgh was called for Tuesday, March 18th. Some 60 members put in an appearance, and the chair was occupied by Dr. G. A Gibson The speaking was all against the action of the town council and a deputation was appointed to wait upon the council and to represent the views of the meeting.

### *Close of the Winter Session.*

The winter session of the classes in the Faculty of Medicine, Edinburgh, close on Friday, March 21st.

### *Death of Mr. Stanley Donald.*

Quite a gloom has been cast over the medical students on the University of Aberdeen by the untimely death on March 17th of one of their number, Mr. Stanley Donald, son of Dr. Donald of Banff. The news of Mr. Donald's death has been received with feelings of deepest regret and genuine sympathy is being extended by all classes of the community to his bereaved relatives.

### *The Strachan Bursary.*

The Strachan bursary for Clinical Medicine and Therapeutics has been won by Mr. Hugh S. Brander, M.A., of Aberdeen.

### *Presentation to Dr. T. W. Ogilvie.*

A large number of the people of Torry met in the Old Free Church, Torry, on March 15th, when Dr. T. W. Ogilvie was made the recipient of a dressing-case and a sporting rifle on the occasion of his leaving for Kimberley. Baillie Meff presided and ex-Lord Provost Mearns made the presentation. Dr. Ogilvie replied suitably.

### *St. Andrews University and the Carnegie Trust.*

The report of the University Court of St. Andrews to the Executive Committee of the Carnegie Trust has now been published. In the prefatory statement an account is given of the improvements which have already been made. The urgent needs of the University arise from the efforts which have thus been made. The average number of students at the University from 1880-81 to 1889-90 was 206. This number has gradually risen to 415 this year, through the admission of women, the addition of Dundee students, and other causes. The most urgent need of the University is the alteration and extension of the buildings of the United College. The present buildings were erected at two periods—the east wing in 1827-29 and the north wing in 1846-49 They were built to accommodate only the classes then in existence, and the class-rooms were laid out in a manner which has now become antiquated, this being especially seen in the case of the class-rooms of chemistry and physics, which are unsuitable in every way. No provision has been made for expansion. There are no separate class-rooms for the chair of education or for the lectureships which have been instituted since 1891 For necessary additions to the present buildings about £10,000 might be sufficient. For separate research laboratories in chemistry and physics £10,000 would be required. In the lectureship department the most urgent need is the establishment of a permanent lectureship in German. Lectureships in geology and applied mathematics might also with great advantage be established. The court are also of opinion that the lectureships in botany, French, history, ancient history, and political philosophy, political economy, German, geology, and applied mathematics should be permanently established in the University. As the salaries of the lecturers on those subjects the charge of an attendant. In the reading-room all the important medical journals are kept on file and the rooms are open to members from 2 to 6 P.M. and from 8 to 11 P.M. The society recently discussed the proposition to have medical inspection of schools for the city of Montreal. No definite arrangement was recommended as the whole matter is to come up again at another meeting shortly. The stated meetings of the society are held on the first and third Fridays of the month from October to June inclusive. The officers for the present year are as follows: President, Dr. George E. Armstrong; Vice-President, Dr. H. S. Birkett; treasurer, Dr. J. M. Jack; secretary, Dr. Alfred T. Bazin; trustees, Dr. G. A. Brown, Dr. F. J. Shepherd, and Dr. James Perrige.

### *The Undergraduates' Medical Society of McGill.*

This society was organised in 1879 through the influence of Dr. William Osler and Dr. Frank Buller, and shortly afterwards it undertook to support a reading-room. That it commenced on a very small scale is apparent seeing that all the literature provided at that time was one daily newspaper and the *Illustrated London News*. In 1886 the faculty took the reading-room under its wing and since that time each medical student is charged $1 for its maintenance along with his other dues In the new medical buildings recently constructed the society is provided with a very handsome reading-room where all the leading daily and weekly papers of the Dominion of Canada and a few of the United States are on file. In addition there are supplied all the leading medical and scientific journals. Very recently a beautiful tablet has been erected in this reading-room to the memories of Harold L. Borden, B.A., of Canning, Nova Scotia, and A. Patrick O'Reilly of Hamilton, Ontario, both of whom lost their lives in active service in South Africa in 1900. Both were medical students. sons of two prominent medical men of the Dominion.

### *A New Hospital in New Brunswick.*

The Chipman Memorial Hospital was opened on the afternoon of Feb. 4th at St. Stephen's, N.B , by the Hon. L. J. Tweedie, Premier of the Province. This hospital, which is situated on the banks of the St. Croix River, a short distance below the town, comprising building, grounds, and modern equipment, has been presented to the town by Lady Tilley, wife of the late Sir Leonard Tilley, formerly Lieutenant-Governor of the Province, and other heirs of the Chipman Estate. It has accommodation for 20 patients, and on the day of its dedication the men of St. Stephen's presented to it $1000.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

### *A Bill to Establish a National Board of Public Health in the United States.*

A BILL has been introduced into the House of Representatives of the United States to establish a National Board of Public Health. It is proposed that such board shall consist of a commissioner and of a representative from each State and territorial board of health, the surgeons-general of the army and navy, the supervising surgeon-general of the Marine Hospital Service, or such other medical officer from either service as may be designated by the chief thereof. The duties of the commission will be to supervise all matters affecting public health and especially the laws relative to quarantine. Much of the work which the proposed board would undertake is now efficiently performed by the United States Marine Hospital Service, and for this reason it is thought by many that the creation of a national commission is unnecessary.

### *Registration of Deaths and Mortality Statistics of the United States.*

The lack of uniformity in the several States of the Union in the methods employed in registering deaths and collecting vital statistics has long been an obstacle in the way of gathering accurate statistics of mortality in the United States. In this country registration heretofore has been done better or worse, or has been wholly neglected, according to the will of separate and independent States, and always without regard to the practice of neighbouring States or to the broader utility of registration for certain purposes of the Federal Government. The United States Census Office, together with a committee of the American Public Health Association, has concluded to take up the matter and to endeavour to introduce the needful changes into the system. The committee of the American Public Health Association has published a circular in which it is stated that it is very desirable that Congress, the United States Census Office, the medical departments of the Government, the legislatures of all the States, their boards of health and registration bureaus, municipal boards of health, and all sanitary, medical, statistical and economic associations should unite in efforts to extend in this country the practice of accurate registration of deaths and the publication and utilisation of the valuable data resulting therefrom. The committee has drawn up what it deems to be the essential requirements of a law for the registration of deaths and the collection of mortality statistics.

### *Amended Vaccination Act for New York State.*

The existing regulations in regard to vaccination in force in New York State will be rendered far more stringent if the Vaccination Bill in its amended form now before the State Legislature becomes law. The Bill in question provides for the compulsory vaccination of school-children, making it incumbent upon superintendents and principals of schools to refuse permission to enter schools to any children who have not been vaccinated or revaccinated within a certain period. Another clause of the Bill provides that every person in a house in which small-pox has broken out shall be vaccinated, and in case of refusal it allows a local board of health to quarantine for 14 days the recalcitrant individuals. The heads of colleges, hospitals, public institutions, fire and police departments, factories, business-houses, &c., are made responsible for the vaccination and revaccination within a certain period of those under them, neglect to comply with these regulations being visited with heavy penalties. The people of New York State, and, indeed, of the United States generally, are in the main conscious of the great benefits conferred by vaccination and seem determined to insist upon the operation being performed efficiently and often enough to check the spread and to modify the virulence of small-pox.

### *The New York State Charities Bill.*

Much dissatisfaction has been aroused throughout New York State by the action of the governor in introducing a Bill whereby the patronage and control of the 14 State charitable and correctional institutions will be taken from the State Board of Charities and lodged with the Executive at Albany. The State Board of Charities has managed these institutions for many years and with satisfactory results, and the resolve of the governor to dispense with its services has given rise to protests not only from the medical journals, but from the lay journals also. The press has condemned the governor's action with remarkable unanimity and on March 3rd the State Board of Charities gave the governor to understand that the members of the board could not conscientiously accept the essential provisions of his Bill; they pointed out that they were opposed to stripping the local boards of managers of their present powers, but would favour any Bill aimed to extend and to safeguard the present system. As a result of the ground taken by the State board, the governor and the special committee of legislators which drafted the proposed Charities Bill could not agree with the members of the State board on a measure which the board would stand for. The chief objection brought against the Bill is that it will place the charitable and correctional institutions of the State, including lunatic asylums, directly in the hands of politicians who it is feared may use the patronage attached to them for political purposes and not for the good of the inmates.

### *Crusade against Vice in Buffalo.*

The ministers of religion and the police authorities of Buffalo have come to an agreement whereby disorderly houses are to be restricted within certain limits, and all thoroughfares are to be kept free from the vicious element. This departure on the part of Buffalo, however, is not a new or untried one in the United States. For nearly 20 years in Minneapolis, Minn., there has been in force a like arrangement. All the saloons have been, and they are now, in an area confined to six blocks in width from the Mississippi River on each side, and houses of prostitution in a narrower limit. This district is regularly patrolled by the police; keepers of houses the candidates of the different parties. Various leagues are organised and electoral circulars are being sent out. One of these which I have seen is an astounding document such as it is hardly possible to believe could have been sent out at the beginning of this century, one, moreover, which is not the work of a practical joker but which is issued by a genuine committee. The committee is composed of provision merchants whom the laws destined to check adulteration, although such laws are very mild and are not applied with any rigour in France, annoy in their nefarious work. These provision dealers propose to take vengeance for the discredit thrown upon articles supplied by them by systematically voting against all Parliamentary candidates who happen to be medical men. Many deputies are medical men, but most of them do not practise and their indifference to all matters which are of interest to the medical profession and even to the question of public health is notorious. All the same the circular in point is worthy of reproduction. It runs thus: "Electors and business men! On the eve of the elections the friend of the small dealers calls your attention to the present very grave danger—namely, the invasion of the Chamber of Deputies by medical men. Oppose medical candidates, replace them by commercial men. And why! Because the trend of hygienists is to exercise an insupportable dictation concerning the supplying of food. To increase their authority these hygienists do not hesitate to exaggerate in an absurd manner the importance of food frauds, and then they pose as saviours of human life. Thus sometimes these hygienists, who are nothing but quacks, accuse purveyors of milk, sometimes wholesale provision dealers or rather grocers. No branch of food-supplying is free from their accusation of fraud and falsification. Defend yourselves, then, against the calumny. The business of food-supplying is already too much discredited, has been for some years too persecuted by the mountebanks of hygiene. They must be given a lesson. Food purveyors of Paris and the provinces! Vote against medical men. Let all parties choose other men to uphold their flag. Let them, for instance, choose food purveyors."

### *Sudden Death.*

At the meeting of the Academy of Medicine held on March 11th M. Lancereaux read a very interesting and surprising paper. He had made 50 post-mortem examinations on the bodies of individuals who had died suddenly and whose death had been attributed, wrongly as it turned out, to embolism or to the rupture of an aneurysm. M. Lancereaux was surprised to find that all the organs were perfectly healthy, particularly the heart, which was empty, as is observed in physiological experiments in the production of death by bulbar anæmia. M. Lancereaux, therefore, had to seek elsewhere for the cause of death occurring while the patient was apparently perfectly well and he attributed it to a gastric reflex which had been observed chiefly in gouty dyspeptics. This form of dyspepsia brought about great irritability of the heart even when it was otherwise normal but especially when the heart was at all dilated or was much overlaid with fat; it was well known that indigestion might easily produce cardiac palpitation, weakness, or even syncope. A sharp blow on the pit of the stomach or the ingestion of ice-water was able to bring about sudden death by arrest of the heart owing to a reflex shock originating in the stomach M. Lancereaux, starting from this point of view, made the remark that most sudden deaths occurred at very significant times of the day, that is to say, from four to five hours after midday or between two and three o'clock in the morning. They, however, rarely occurred in the morning between 10 and 11 o'clock—that is to say, they occurred at such a distance after a meal that digestive troubles were beginning to be felt in dyspeptics who suffered from dilated stomach. The way to ward off this catastrophe was to order dyspeptics an appropriate diet, such as grilled meat, eggs, and green vegetables; they should drink nothing but water or should live entirely on milk and they should have their meals at regular intervals. All acid substances should be forbidden and a little bicarbonate of soda should be taken. The excitability of the nervous system could be modified by bromides and opium. If there was much cardiac palpitation a little digitalis might be given, and life must be taken quietly. If syncope came on rhythmical traction of the tongue, slapping on the face, and injections of ether, caffeine, and above all of morphia might be given.

March 18th.

# CANADA.

(FROM OUR OWN CORRESPONDENT.)

### *Attendance at McGill University.*

THE total number of students attending classes at McGill University during the present session is put down at 1114, divided amongst the different faculties as follows: law, 60; medicine, 490; arts, 294; applied science, 254; and veterinary science, 16. In 1901 the total number of degrees conferred was distributed as follows: law, 17; medicine, 93; arts, 42; applied science, 51; and veterinary science, three.

### *Death of a Prominent Alienist.*

Dr. Richard Maurice Bucke, superintendent of the Asylum for the Insane at London, Ontario, died on Feb. 19th. About 11 o'clock on that evening before retiring for the night he took a stroll on the verandah of his residence, when he slipped accidentally upon some ice, the fall resulting in immediate death. Dr. Bucke was born in 1837 at Methwold, Norfolk, England, at which place his father was curate. Coming to Canada at an early age, he graduated in medicine at McGill University in 1862 as gold medalist of his class. He entered the Ontario asylum service in 1876 as superintendent of the Hamilton Asylum, being transferred to the superintendency of the London Asylum in the following year, a position which he held up to the time of his unfortunate death. He was a life-long friend of the poet Walt Whitman and his literary executor, and he had the largest and best Whitman collection in the world. Dr. T. A. McOollum of Dunnville, Ontario, a prominent surgeon of the Niagara Peninsula, has been appointed as his successor.

### *An Association of the Hospitals of Ontario.*

Representatives from the leading hospitals of the province of Ontario recently met in Toronto for the purpose of forming the Ontario Hospital Association, the object being to insure united action in guarding the interests of the hospitals in the province. The movement was instituted by Ottawa hospital authorities, and has been brought about owing to the falling-off in hospital funds. The cause of this is laid at the door of the Ontario Government which lately cut down the grant to 30 cents per day, and further to the fact that the Succession Duties Act bore so heavily upon the estates of wealthy citizens that nowadays these dying left nothing to the hospitals as formerly, believing that a portion, say 10 per cent., of the duties were handed over to the hospitals by the Government. The new association will meet every year in Toronto at the time of the meeting of the provincial legislature. The officers will consist of a president, five vice-presidents, a secretary-treasurer, and a committee of seven. Dr. John Ferguson of the Western Hospital, Toronto, was elected the first secretary-treasurer.

### *A New Medical Building for Toronto University.*

The medical department of Toronto University will erect a fine new building in the Queen's Park, adjoining the other university buildings, at a cost of $125,000. It will be constructed on the same plan as the new medical building of Harvard University. The laboratories will be on the "unit system," each one being 23 by 30 feet and capable of being enlarged or decreased in size to suit large or small classes. The faculty will probably lease a portion of the building when completed to the arts department of the University.

### *The Efficacy of Vaccination Proven at Montreal.*

Since May last, according to Dr. J. E. Laberge of the Montreal Contagious Diseases Hospital, there have been in that institution 240 cases of small-pox, and in no instance had any of the patients been vaccinated before contracting the disease Besides, a staff of 18 persons, medical men and nurses, have been in daily and hourly contact with these small-pox patients, and not one of them has contracted the disease. The special order of the Provincial Board of Health of Quebec with regard to compulsory vaccination has been pretty generally obeyed throughout the province, as over 347 municipalities have notified the board that they have adopted this by-law.

### *Montreal Medico-Chirurgical Society.*

During the past year this society has secured fine new commodious quarters, which comprise a large meeting-hall capable of seating 125 persons, a cloak-room, a library-room, a reading-room, and a committee-room. All are in

British Medical Association the question of meeting in consultation the medical officers of the Associated Friendly Societies' Institute at Brisbane was discussed. It was stated that the establishment of the institute had enabled the friendly societies to dictate terms to the medical profession, and the objections to it were (1) that the sum paid per member to its medical officers was less than that paid to medical officers of friendly societies not connected with the institute; and (2) that no one was excluded from membership of the institute, whatever his income or position might be. It was finally resolved unanimously:—

1. That members of the branch shall not meet in consultation the medical officers of the Brisbane Associated Friendly Societies' Medical Institute.

2. That members of the branch shall not meet in consultation medical men who meet in consultation the medical officers of the Brisbane Associated Friendly Societies' Medical Institute.

3. That, except by a special resolution of the branch at a meeting called for the purpose, the members of the branch shall not meet in consultation medical men who now hold, or shall have held, the position of medical officer to the Brisbane Associated Friendly Societies' Medical Institute.

4. That Resolution 3 shall also apply to medical men referred to in Resolution 2.

5. That the foregoing resolutions be not put into effect until they have been ratified at the next general meeting (Friday, Feb. 7th, 1902) and until each member of the branch in Brisbane has been made acquainted with them.

6. That a printed copy of the foregoing resolutions be sent to every medical practitioner in Brisbane.

Feb. 11th.

# Obituary.

## SIR WILLIAM GUYER HUNTER, K.C.M.G., M.D. ABERD., F.R.C.P. LOND., F.R.C.S. EDIN.

WE much regret to announce the death of Sir William Guyer Hunter, which occurred on Friday, March 14th, at his residence, Anerley-hill, Upper Norwood.

Sir William Guyer Hunter was the eldest son of the late Mr. Thomas Hunter, of Catterick, Yorkshire, and was born in 1829, being in his seventy-third year at the time of his death. He received his education at King's College School and King's College Hospital, and in 1849, at the earliest possible opportunity, he became a Member of the Royal College of Surgeons of England, graduating later in Medicine at Aberdeen University and taking, also, the Fellowship of the Royal College of Surgeons of Edinburgh. In the following year he entered the medical service of the Bombay Presidency, where he was destined to take part in stirring events. He served through the second Burmese war of 1852–53 which led to the annexation of Pegu, and during the campaign nearly fell a victim to a severe attack of cholera. For his services in this war he received a medal with clasp. Five years later came the Indian Mutiny, through which he served as a surgeon, obtaining brevet rank. At the time of the mutiny he was civil surgeon in Upper Sind, and the strain upon him compelled him, when the sepoys had been suppressed, to return home on furlough. He was recalled to take up a vacant professorship in the Grant Medical College, Bombay, when he was also elected physician to the Jamsetjee Hospital. In 1876 he was appointed principal of the Grant Medical College and in 1877 was specially promoted to the rank of surgeon-general. In 1878 he made a valuable report to the Government of Bombay upon the famine fever of the previous year, for which he was specially thanked by the Indian Government. It is a melancholy coincidence that the brilliant Anglo-Indian, Sir Richard Temple, whose death took place on the day following the death of Sir William Guyer Hunter, received the report in question, for he had just been made Governor of Bombay, in recognition of his excellent work in connexion with the famine troubles. In 1879 Sir William Guyer Hunter was appointed by Sir Richard Temple Vice-Chancellor of the University of Bombay—a distinction, at any rate at that time, usually reserved for members of the Legislative Council and judges of the High Court in India. In 1880, on a new organisation of the Indian Medical Service being promulgated, Sir William Guyer Hunter retired from the service, leaving behind him an admirable record of arduous and enlightened labour. A highly complimentary order referring to him was issued by the Government, a public address was presented to him by the inhabitants of Bombay, and a subscription was raised to found a scholarship and to present him with his portrait to be placed in the Grant Medical College.

In 1883, very soon after his retirement from the service, he was sent to Egypt by the British Government to inquire into the cause of epidemic cholera in Egypt. His great experience of cholera during his service in India made him well qualified to discharge the mission. Cholera, it may be remembered, had broken out with suddenness and severity at Damietta, and at Mansourah, some 30 miles up the Nile, and the position of Damietta on the Mediterranean coast made it of the utmost importance to ascertain the origin and nature of the outbreak. Surgeon-General Hunter was prompt to speak. Within a few weeks of his arrival in Egypt he submitted a brief report, stating that cholera of the ordinary Indian type had to be dealt with immediately by the formation of an adequate sanitary service; that "quarantines" and "cordons" had never more completely failed to arrest the disease than they had done in Egypt; and that to talk of sanitation in connexion with Cairo and other Egyptian centres of population was an abuse of words. His subsequent full reports to Lord Granville and certain papers read before the Medical Society of London and the Epidemiological Society came in for a great deal of criticism. He repudiated entirely the contagiousness of cholera, and regarded the epidemic in Egypt as an exacerbation of an endemic form of cholera which had been existent in the country for at least 30 years. His views were obviously based upon insufficient and untrustworthy evidence, while, curiously enough, the cases that he recorded went to prove exactly the influence of contagion and the spread along lines of human intercourse which he denied to exist. But the good done by his vigorous indictment of the unhealthy conditions prevailing in Cairo remained, and the question as to whether he had misinterpreted the meaning of facts which he had laboured to collate did not detract from that good. Surgeon-General Hunter was made a K.C.M.G. for his services on this occasion.

In 1885 Sir William Guyer Hunter entered Parliament as Conservative member for Central Hackney and was returned again in the following year for the same constituency, for which he sat until 1892. He was a sound but infrequent speaker, contributing to debate only when his special experience made his views of value.

He was twice married—firstly to a daughter of the Reverend C. Packe, vicar of Ruislip, and, secondly, to a daughter of Mr. J. Stainburn.

Sir William Guyer Hunter was honorary surgeon to His Majesty the King and consulting physician to Charing Cross Hospital. All medical men will feel that in him they have lost a colleague who did their profession great credit. A shrewd and laborious man, he made a great reputation for himself in India while still a young man, and until the close of his life he worked hard in responsible positions for the good of his generation.

## SURGEON-GENERAL JOHN ROBERT THEOBALDS,

LATE INDIAN MEDICAL STAFF, MADRAS PRESIDENCY.

SURGEON-GENERAL J. R. THEOBALDS died at his residence at Weston-super-Mare on March 7th in his eightieth year. The deceased was born in India, and in 1848 he entered the Indian Medical Staff, and retired in 1880, after 32 years' service, with the rank of Surgeon-General. Surgeon-General Theobalds whilst in the service was engaged in the pursuit of the notorious Tantia Topee during the Indian Mutiny. His skill as a surgeon and his management of the various hospitals over which he had the control are spoken of in the highest terms in the Government reports. On his retirement he settled in Weston-super-Mare where he took the greatest interest in municipal matters and gave his personal and financial support to a large number of the local benevolent institutions. Surgeon-General Theobalds was of a genial and kindly disposition and will be much missed in Weston-super-Mare. He died after a short illness from cardiac failure following an attack of pneumonia. The funeral, which took place on March 13th, was largely attended.

---

THE *Star* points out that the pages of "Burke" contain the names of two persons, both medical men, who are in their ninety-fourth year—Sir Charles Nicholson, M.D., who held for a considerable time a distinguished position in the Legislature of New South Wales, and received a baronetcy in 1859; and Sir Henry Pitman, M D. Cantab., who was for many years registrar of the Royal College of Physicians of London, and who was knighted in 1883.

of ill-fame are regularly fined, and it is asserted by inhabitants of the far western city that the adoption of the system has been attended with complete success and that no city of the Union can show a cleaner street record than can Minneapolis. The proper government of American cities is a most serious question and one that is arousing the attention of philanthropists and sanitarians from a moral and physical standpoint. The control of prostitution is an especially difficult feature with which to deal successfully, and in no city are the obstacles in the way of solving the problem more obvious than in New York. A committee of 15 was appointed to investigate the matter and to suggest remedies and it has lately published a volume dealing exhaustively with the subject. The working of the arrangement come to at Buffalo will therefore be watched with interest throughout the United States, and if successful there other large cities may be induced to enter into a like arrangement.

### *Report on Mosquitoes in Baltimore.*

In the February-March number of the *Bulletin of the Johns Hopkins Hospital* is a report by Mr. Leonard K. Hirshberg and Mr. Gustavus C. Dohme on the result of their investigations of the distribution of the anopheles claviger in the vicinity of Baltimore. They place no faith in the use of oil as an exterminator of the larvæ of the mosquitoes and declare that it is hopeless to expect to eradicate malaria by such means. In concluding their observations these investigators say: "Of special importance is the careful screening of doors by wire gauze or mosquito netting as suggested by Celli. Where this cannot be done fitting the beds with netting will offer security, inasmuch as most anopheles bite at night." They recommend that cases of malarial infection shall be reported to the City Board of Health just as are the contagious diseases, thus enabling precautions against the spread of malaria to be carried out under the proper supervision.

### *Mosquitoes and Dengue.*

Dr. Harris Graham, professor of pathology at the American College, Beyrouth, Syria, contributed to the *Medical Record* of Feb. 8th an article on the Mode of Propagation and Pathology of Dengue. Dr. Graham points out that since the epidemic of 1889 a strong opinion has prevailed among those who have given the matter careful study that dengue is a purely contagious disease, but that up to the present no logical explanation has been offered of the soundness of this theory. He therefore at the beginning of the epidemic which has prevailed in and around Beyrouth since July, 1901, commenced a series of experiments in order to determine, if possible, whether the culex which exists in perfect swarms in the city could carry the dengue from person to person. The careful experiments carried out by Dr. Graham convinced him that the mosquito was the means of carrying the disease and he was therefore forced to the conclusion that the cause must be sought in the blood. The blood of patients whose constitutional symptoms were marked and in whom the course was typical were systematically examined and the parasite was, in Dr. Graham's opinion, definitely isolated. It is described as resembling in many ways the plasmodium malariæ, but its cycle of production or formation in the human blood is so much longer than that of the malarial parasite that the changes in its life-phase come more slowly and are more difficult to follow. Dr. Graham concludes his paper by saying: "It may not be absolutely proved that this hæmatozoon is the cause of the dengue, but its constant presence in the red blood corpuscle during the fever, its resemblance to the parasite of the Texas cattle fever, its likeness in manner of growth and mode of propagation (by the mosquito) to the malarial parasite, all point in the same direction and lead us to believe by analogy, if by no other way, that in this parasite we have the cause of dengue."

March 10th.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

### *Australasian Science Association.*

THE meeting of the Australasian Association for the Advancement of Science was held at Hobart in the first week in January. The President, Professor F. W. Hutton, F.R.S., Director of the Christchurch (N.Z.) Museum, chose as the subject of his address "Evolution and its Teaching." He explained the theory of the evolution of the constellations from the cosmic dust and said it was possible that the creation of the cosmic dust itself occurred less than 200,000,000 years ago. He then traced the evolution of life on the earth from protoplasm. The first germ of ethical evolution was in parental affection, and morality appeared to have arisen from sympathy; and the long and constant use of formal morality made it instinctive and gave rise to conscience. It could not be thought that this process was confined to the earth and long after the sun was cold and dark other stellar systems would probably continue the development of life and mind. The conclusions of science showed that mind pervaded all matter, and in the composition, size, and position of the earth there was overwhelming evidence of design. Physical evolution, biological evolution, and psychological evolution were still going on. So far as the earth was concerned physical evolution had reached its optimum, so had biological evolution in man. Psychological evolution was still going on and the development of human mind was still in its infancy. This psychological evolution was not making for happiness, and ethical evolution seemed leading up to something not displayed on earth and which they could only conceive as a further development when mind was freed from matter.—The President of the Hygiene Section was Sir T. N. Fitz-Gerald, C.B., F.R.C.S. Irel., whose address was entitled "The Nature of Disease." Of the extensive causes of disease heredity, he said, stood foremost but did not occupy the important position now that it did formerly. Nervous affections, from insanity to migraine, were transmissible. Deformities and disfigurements due to defective development were handed on, though uncertainly. Deformities were rather the result of what horse-breeders called a "nick." Two perfectly healthy people free from any deformity married and their entire family might display evidences of imperfect development, as cleft palate, auricular appendages, &c. Their offspring in turn might beget healthy, normal children. It was doubtful if intermarriage had much to do with the appearance of deformities. Heredity formed a small factor in the causation of tuberculosis and assurance companies loaded lives on this account in a most reckless and senseless manner. As to cancer, also, the tendency is to doubt its hereditary character and to assign apparent inheritance to coincidence or to infection. It had yet to be brought home to the public that lunatic asylums, hospitals, and benevolent asylums were charged with the consequences of syphilis, which still stalked rampant through the land, while if controlled by the regulation of the class by which it was spread tabes and general paralysis might be almost wiped out. Another scourge of society and cause of disease was alcoholism. Habitual drunkards should be regarded as pests, liable to be removed and to be confined in the same manner as fever patients. Among the poorer classes the habit of drinking was largely acquired from the monotony of their lives, and more good would be done by affording better resources in the way of amusements than by restrictive legislation.—Mr. T. A. Coghlan, Government statistician of New South Wales, contributed an interesting paper on Child Measurements, giving the results of his investigations of a number of children attending the Sydney schools. He found that the children of the non-labouring class were physically more robust than those of the labouring class—that hindrances to growth showed themselves at an early age, and that many of the conditions that made for evil were remediable. The results of measurements of height corresponded with observations elsewhere. As to weight the Sydney boys were slightly heavier than English boys up to nine years—thence to 12 years they were slightly lighter. By 12½ years the Australian boy regained his superiority in weight and at 13 years he was about three pounds heavier, and the advantage was maintained during adolescence. The prevailing colour of the skin and hair was blonde and the eyes were most frequently blue. The chest expansion was small compared to that of European children.—At the first meeting of the association the following resolution was passed:—

> That the sanitary legislation of every State should contain provision for the notification of phthisis as an infectious disease and for the prevention of its spread by the taking of proper precautions, especially through the sputum of consumptives; that there should be provided in every State at least one sanatorium where tuberculosis patients could be treated on terms within the means of all.

### *The Queensland Branch of the British Medical Association and the Brisbane Associated Friendly Societies' Medical Institute.*

At the January meeting of the Queensland Branch of the

two to Mrs. Evans's Home at Solihull. In some cases railway fares have been paid to enable patients to go into the country, or towards their expenses in boarding at farm houses. Surgical appliances have been supplied and in some instances patients have been relieved at their own homes for many consecutive weeks with milk, groceries, coal, or meat. During the past year the patients and their friends have contributed £7 15*s.* 2*d.* towards expenses.

The Liverpool School of Tropical Medicine.—The report of the Liverpool School of Tropical Medicine for 1901, being the third year of the existence of the school, shows that steady progress has been made in the work during the past year. The hospital report states that four nurses were trained in 1901 at the expense of the school in the special tropical ward of the Royal Southern Hospital. Three of these nurses were sent by the Colonial Nursing Association of London. In connexion with the hospital a special department for out-patients suffering from tropical diseases was opened in October last which will be of great value to the school. During the year 131 cases were treated. Financial support has been freely forthcoming from those interested in the work of the school, but its operations entail a very large annual expenditure and as the school is not endowed it is to be hoped that liberal support will continue to be given.

British Laryngological, Rhinological, and Otological Association.—Under the chairmanship of their President, Dr. J Macintyre of Glasgow, the members of the British Laryngological, Rhinological, and Otological Association held their annual dinner on March 14th at the Café Royal, Regent-street, London. Dr. C. O Hawthorne proposed the toast of "The Association," and said that in the wide field of medicine general practitioners were debtors to the association for distinct contributions to their knowledge and their capacity to deal with suffering humanity The President proposed the toast of "The Guests," which was responded to by Sir William Dunn, M.P., and Mr Wilhelm Ganz Dr R H. Woods of Dublin assisted in the entertainment of the guests by a humorous recitation and Dr. R A. D. Daniel contributed some humorous songs. The music provided by Mr. Wilhelm Ganz, with the assistance of Sénor Guetary and Mr. Mervyn Dene, was highly appreciated.

Royal Institution.—The following are the lecture arrangements at the Royal Institution after Easter:—Dr. Allan Macfadyen, three lectures on Recent Methods and Results in Biological Inquiry; Professor F. York Powell, three lectures on English Kings and Kingship; Professor Karl Pearson, three lectures on the Laws of Heredity, with Special Reference to Man (the Tyndall Lectures); Professor Dewar, three lectures on the Oxygen Group of Elements; Dr. A. Smith Woodward, three lectures on Recent Geological Discoveries; Mr. M. H. Spielmann, three lectures on Contemporary British Sculpture: Mr. W. H Cummings, three lectures on British National Song (with musical illustrations); Professor Walter Raleigh, three lectures on Poets and Poetry: and Professor Brander Matthews, three lectures on the Development of the English Drama: (1) the Art of the Dramatist, (2) the Drama of the Middle Ages, and (3) the Drama under Elizabeth The Friday evening meetings will commence on April 11th when Professor Dewar will deliver a discourse on Problems of the Atmosphere. Succeeding Friday evening discourses will be delivered by Sir John H. A. Macdonald, Dr. J. Mackenzie Davidson, Sir Robert Ball, Sir Benjamin Baker, Professor A. E. Tutton, and other gentlemen.—Magnetism in Transitu formed the subject of the Friday evening discourse delivered on March 14th by Professor Silvanus Thompson. The subject was illustrated not only by diagrams, models, and numerous experiments, but also by pictures projected by means of the animatograph, in which diagrams of lines in motion represented the formation, growth, and disappearance of magnetic lines of force. One of the experiments was of a remarkable nature. Faraday showed long ago that when an electric current was passed through a wire an induced current was created in a second wire parallel to, but insulated from, the first one. The currents in the two wires travelled in opposite directions. Professor Thompson found that the magnetic lines of force existing between the two wires could be twisted in space by passing one wire through one loop and the other wire through the other loop of a figure-of-8 made of thin iron rod. The primary and the induced currents then travelled in the same direction. A series of 20 such figures-of-8, each so made that the metal composing it did not touch at the point of crossing, was fixed edgeways on a board about two feet long, all of them separate and similarly situated; the straight primary wire passed through one row of loops and the secondary wire through the other row.

Chesterfield Hospital.—The annual meeting of the governors of, and subscribers to, the Chesterfield Hospital, was held on March 13th. The report stated that during the year 420 persons were admitted, being 10 less than in 1900. The total number treated was 462 Of the 42 patients in the hospital at the end of 1900, 33 were discharged cured, six were relieved, and three were discharged at their own request. Of those admitted in 1901, 315 were discharged cured, 19 were relieved, 38 died, and 48 remained under treatment. The average stay of each patient was 33 92 days, against 28 63 days in 1900. In the out-patient department 2076 persons received benefit, as compared with 1858. There were 1211 casualties dealt with. The total expenditure for the year, exclusive of extraordinary expenditure, was £3421 13*s.* 4*d.* This exceeds the amount of any previous year owing to the number of patients. The extraordinary expenditure amounted to £752, and was incurred in connexion with the sanitary and heating arrangements. The report having been adopted the chairman announced that a gift of £2240 had been received from the trustees of the Renishaw Park Colliery Explosion Fund.

Freemasonry.—*University of London Lodge, No. 2033.*—The usual spring meeting of this lodge was held at Freemasons' Hall on March 13th. In the absence of the Worshipful Master, Dr. Samuel Hague, the chair was occupied by Brother H. W. Kiallmark, P.G.D. Amongst those present were Dr. A. E Sansom, Mr. R. A. Germaine, M.A. (Recorder of Lichfield), Mr. Beaumont Morice, LL.B. (Recorder of Hythe), Dr. A. W. Burrell, and Mr. F. E. Lemon, M.A., treasurer. The secretary of the Chère Reine Lodge was a guest The Permanent Committee brought up a proposal whereby busy members might be enabled to keep their names on the books without being expected to attend the meetings so regularly as those desiring to go forward and to take up office in the usual way. As this lodge numbers amongst its members a considerable number of graduates whose engagements are numerous and increasing and who yet do not wish their connexion with the lodge to be severed, this amendment of by-laws, if adopted, is likely to prove useful. A general feeling was expressed that the lodge has now assumed such a degree of importance that a petition should be sent to the University asking that its periodical meetings should be noted on the agenda published in the *University Gazette.*

Irish Medical Schools' and Graduates' Association.—The annual general meeting of the above association was held on March 17th (St. Patrick's Day) at the Hotel Cecil, London, when the out-going President, Dr. William Alexander (Liverpool) resigned the chair to Sir Philip C. Smyly (Dublin). There was a very large attendance of members. A vote of condolence with the relatives of the late Sir William Mac Cormac, a foundation member and former president of the association, was passed. The members and their guests, to the number of 257, subsequently sat down to dinner under the chairmanship of Sir Philip Crampton Smyly, the guests of the evening being Lord Rathmore, Sir John Edge, and Dr. Brendan MacCarthy. Dr. Brendan MacCarthy was introduced to the President by Mr. P. J. Freyer and was presented with the Arnott Memorial Medal founded by Mr. David Arnott in memory of his father, the late Sir John Arnott. Dr. MacCarthy in the autumn of last year joined the late Mr. William Smyth in attending the typhus patients during the epidemic in the island of Arranmore on the coast of Western Donegal. The only boat that these two medical men could get to convey the sick from the island sank after they reached the main land because of its unseaworthiness. Dr. MacCarthy said that if it had not been for the tragic way in which Mr. Smyth died he did not think that anything would have been heard of the matter. "Our Defenders" was proposed by Dr. W. E. St. Lawrence Finny and was responded to by Inspector-General W. H. Lloyd, R.N., Brigade-Surgeon W. Ffolliott, and Surgeon-Major J. J. de Zouche Marshall; A.M.R Dr. T. Gilbart Smith gave the toast of "Our Guests," to which Lord Rathmore replied in an eloquent speech in

Ehrhardt, assistant surgeon in the Surgical Clinic, has been recognised as *privat-docent* of Surgery.—*Munich:* Dr. F. Wanner has been recognised as *privat-docent* of Otology.—*Rostock:* Dr. Wolters of Bonn has been appointed Extraordinary Professor of Dermatology.—*Strasburg:* Dr. Weidenreich, assistant in the Frankfort Institute for the Investigation of Cancer, has been appointed First Assistant in the Anatomical Institute.

ST. MARY'S DAY NURSERY AND HOSPITAL FOR SICK CHILDREN, PLAISTOW.—In connexion with this institution there have been during the year 1901 742 in-patients, 3553 out-patients, 14,664 casualty patients, and 71,010 attendances. The attendances show an increase of 11,766 over last year's figures. The average cost per bed occupied per year was £59 *7s* 3$\frac{1}{10}$*d*. Efforts are being made to raise funds for the building of a new hospital, for which not less than £25,000 will be required.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA PARK.—The annual general meeting of the governors of this hospital was held on March 4th at Gresham College, when Sir E. Sassoon, M.P., treasurer, presided. The report stated that the heavy decrease in the amount received from legacies, together with the greatly-increased number of in-patients and out-patients, accounted very largely for the unavoidable sale of £2000 stock to meet the current expenses of the year. The chairman, in moving the adoption of the report, said that during the year 966 in-patients were admitted as new cases, showing an increase of 134. In the out-patient department 9678 new cases were treated, showing 62,931 attendances, 2128 in excess of those of the year 1900 A nurses' home was to be built within the precincts of the hospital at a cost of from £8000 to £9000

ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.—The report of this hospital for the year ending Dec. 31st, 1901, stated that during the period under notice the outdoor patients treated at the dispensary numbered 8247, involving 28,990 separate attendances. The dispensary sisters and nurses paid 1439 special visits to patients at their homes to see that the instructions of the medical men were properly attended to and to supply nourishment in the more necessitous cases. 810 patients were treated at the hospital, and there was an average of 100 cases on the books as awaiting admission at the close of every month. Good work is done by this institution but it is greatly hampered in its ministrations through want of funds. The income is far short of the ordinary expenditure. Moreover, the increased work of the hospital has necessitated the provision of a country branch which is in course of erection.

CRAIG COLONY FOR EPILEPTICS.—The eighth annual report of this institution, founded in honour of the late Oscar Craig of Rochester, N.Y., the objects of which are to "secure the humane, curative, scientific, and economical care and treatment of epileptics," states that on Oct. 1st, 1900, the colony had 612 patients, 329 of whom were males and 283 females. During the year 259 patients were received—198 males and 61 females; while during the same period 81 were discharged, 34 died, and 13 were transferred as insane to State hospitals. On Sept. 30th, 1901, there were 743 patients in the colony, 440 of whom were males and 303 females, making an actual gain of 131 for the year. The death-rate for the year, it will be noticed, is less than 5 per cent. The cost of maintenance per head during the year was $762 less than in the previous year. In connexion with the colony Dr. Frederick Peterson offers a prize of $200 for the best contribution to the pathology and treatment of epilepsy, originality being the main condition. The prize is open to universal competition, but all manuscripts must be submitted in English. Essays will be judged by a committee of three members of the New York Neurological Society and the award will be made at the annual meeting of the board of managers of the Craig Colony on Oct. 14th, 1902. The essay must be accompanied by a sealed envelope containing the name and address of the author and bearing on the outside the motto or device which is inscribed upon the essay. The successful essay will become the property of the Craig Colony for Epileptics. Manuscripts should be sent to Dr. Frederick Peterson, 4 West 50th Street, New York City, on or before Sept. 1st, 1902.

FEMALE SANITARY INSPECTOR.—The Rochdale Town Council are making what is for them a new departure in appointing a female sanitary inspector at "28s. a week and uniform." The chairman of the Health Committee gave good reasons for proposing the appointment, saying that while a very large reduction in the death-rate had taken place during the last 20 or 25 years, there had been very little difference in the deaths of infants. "A female sanitary inspector was better able to approach parents and recommend to them suitable food, clothing, and other matters with respect to infants than a male inspector could." In Manchester the health visitors employed by the Ladies' Health Society perform this useful function.

LITERARY INTELLIGENCE.—Messrs. Harrison and Sons, 59, Pall-mall, S.W., will shortly reissue Banting's well-known work under the title of "The Rational Cure for Corpulency." The book has been revised and brought up to date.—In April the fourth edition of "The Operations of Surgery" will be published This new edition has been subjected to a thorough revision at the hands of Mr. W. H. A. Jacobson and Mr. F. J. Steward, surgeon and assistant surgeon respectively to Guy's Hospital. The work will be found to contain 1524 pages in royal 8vo size in place of 1352 pages in demy 8vo, while there will now be 152 additional illustrations, bringing up the number to 550. To meet the convenience of the reader it has been decided to issue the book in two volumes. Messrs. J. and A. Churchill are the publishers.

ROYAL DENTAL HOSPITAL OF LONDON.—On March 13th the annual general meeting of the governors of this hospital was held at the new hospital in Leicester-square, the chairman of the managing committee, Mr. John Hampton Hale, a vice-president of the institution, being in the chair. The report of the committee opened with an appreciation of the great honour conferred on the hospital by His Majesty the King in becoming its patron and by commanding that it should in future be known as the "Royal Dental Hospital," an honour which, the committee felt, would go far to emphasise the worthiness of the objects of the charity. The new buildings were now as complete in every detail as could be suggested by modern science, and they had during the past nine months been open for the reception of patients. During the year now closed 70,040 cases had been treated, an increase of 864 over the previous year and 50,785 more than the number treated in 1874 (the first year of the hospital's existence). Though the committee was gratified to record a small increase in the income, yet it was far from sufficient for the needs of the institution and an earnest appeal was made for increased help to meet the payments for extinguishing the debt and the additional expenses entailed by the extra service and the higher rates and taxes, &c., due to the enlarged buildings and the more efficient administration. A vote of thanks to the Chairman, proposed by Mr. Morton Smale, the dean of the school, closed the proceedings.

THE QUEEN'S HOSPITAL, BIRMINGHAM.—This hospital has been enlarged recently at a cost of £40,000. The annual report states that provision has been made for an increase in the number of beds to 132 for the reception of accidents and urgent medical, surgical, ophthalmic, and obstetric cases, an addition which has considerably increased the expenditure of the hospital. The in-patients treated last year amounted to 2169 and the out-patients to 288,895 The yearly expenditure is over £10,000, the whole of which sum, with the exception of about £1000 received from investments, is dependent upon voluntary offerings and annual subscriptions. The report of the Queen's Hospital Aid Society for 1901 shows that the work of the charity has gone on increasing, and it fills a useful place in assisting the patients of the hospital. During the past 12 months 57 patients have been sent to Blackwell; six to the Home of Rest, Sutton; five to Sister Dora Home, Milford; and nine to the Stratford-on-Avon Nursing Home. Besides these, between 30 and 40 children have been sent from the wards to Moseley Hall and

two to Mrs. Evans's Home at Solihull. In some cases railway fares have been paid to enable patients to go into the country, or towards their expenses in boarding at farm houses. Surgical appliances have been supplied and in some instances patients have been relieved at their own homes for many consecutive weeks with milk, groceries, coal, or meat. During the past year the patients and their friends have contributed £7 15*s.* 2*d.* towards expenses.

The Liverpool School of Tropical Medicine.—The report of the Liverpool School of Tropical Medicine for 1901, being the third year of the existence of the school, shows that steady progress has been made in the work during the past year. The hospital report states that four nurses were trained in 1901 at the expense of the school in the special tropical ward of the Royal Southern Hospital. Three of these nurses were sent by the Colonial Nursing Association of London. In connexion with the hospital a special department for out-patients suffering from tropical diseases was opened in October last which will be of great value to the school. During the year 131 cases were treated. Financial support has been freely forthcoming from those interested in the work of the school, but its operations entail a very large annual expenditure and as the school is not endowed it is to be hoped that liberal support will continue to be given.

British Laryngological, Rhinological, and Otological Association.—Under the chairmanship of their President, Dr. J. Macintyre of Glasgow, the members of the British Laryngological, Rhinological, and Otological Association held their annual dinner on March 14th at the Café Royal, Regent-street, London. Dr. C. O. Hawthorne proposed the toast of "The Association," and said that in the wide field of medicine general practitioners were debtors to the association for distinct contributions to their knowledge and their capacity to deal with suffering humanity. The President proposed the toast of "The Guests," which was responded to by Sir William Dunn, M.P., and Mr. Wilhelm Ganz. Dr. R. H. Woods of Dublin assisted in the entertainment of the guests by a humorous recitation and Dr. R. A. D. Daniel contributed some humorous songs. The music provided by Mr. Wilhelm Ganz, with the assistance of Sénor Guetary and Mr. Mervyn Dene, was highly appreciated.

Royal Institution.—The following are the lecture arrangements at the Royal Institution after Easter:—Dr. Allan Macfadyen, three lectures on Recent Methods and Results in Biological Inquiry; Professor F. York Powell, three lectures on English Kings and Kingship; Professor Karl Pearson, three lectures on the Laws of Heredity, with Special Reference to Man (the Tyndall Lectures); Professor Dewar, three lectures on the Oxygen Group of Elements; Dr. A. Smith Woodward, three lectures on Recent Geological Discoveries; Mr. M. H. Spielmann, three lectures on Contemporary British Sculpture; Mr. W. H. Cummings, three lectures on British National Song (with musical illustrations); Professor Walter Raleigh, three lectures on Poets and Poetry: and Professor Brander Matthews, three lectures on the Development of the English Drama: (1) the Art of the Dramatist, (2) the Drama of the Middle Ages, and (3) the Drama under Elizabeth. The Friday evening meetings will commence on April 11th when Professor Dewar will deliver a discourse on Problems of the Atmosphere. Succeeding Friday evening discourses will be delivered by Sir John H. A. Macdonald, Dr. J. Mackenzie Davidson, Sir Robert Ball, Sir Benjamin Baker, Professor A. E. Tutton, and other gentlemen.—Magnetism in Transitu formed the subject of the Friday evening discourse delivered on March 14th by Professor Silvanus Thompson. The subject was illustrated not only by diagrams, models, and numerous experiments, but also by pictures projected by means of the animatograph, in which diagrams of lines in motion represented the formation, growth, and disappearance of magnetic lines of force. One of the experiments was of a remarkable nature. Faraday showed long ago that when an electric current was passed through a wire an induced current was created in a second wire parallel to, but insulated from, the first one. The currents in the two wires travelled in opposite directions. Professor Thompson found that the magnetic lines of force existing between the two wires could be twisted in space by passing one wire through one loop and the other wire through the other loop of a figure-of-8 made of thin iron rod. The primary and the induced currents then travelled in the same direction. A series of 20 such figures-of-8, each so made that the metal composing it did not touch at the point of crossing, was fixed edgeways on a board about two feet long, all of them separate and similarly situated; the straight primary wire passed through one row of loops and the secondary wire through the other row.

Chesterfield Hospital.—The annual meeting of the governors of, and subscribers to, the Chesterfield Hospital, was held on March 13th. The report stated that during the year 420 persons were admitted, being 10 less than in 1900. The total number treated was 462. Of the 42 patients in the hospital at the end of 1900, 33 were discharged cured, six were relieved, and three were discharged at their own request. Of those admitted in 1901, 315 were discharged cured, 19 were relieved, 38 died, and 48 remained under treatment. The average stay of each patient was 33·92 days, against 28·63 days in 1900. In the out-patient department 2076 persons received benefit, as compared with 1858. There were 1211 casualties dealt with. The total expenditure for the year, exclusive of extraordinary expenditure, was £3421 13*s.* 4*d.* This exceeds the amount of any previous year owing to the number of patients. The extraordinary expenditure amounted to £752, and was incurred in connexion with the sanitary and heating arrangements. The report having been adopted the chairman announced that a gift of £2240 had been received from the trustees of the Renishaw Park Colliery Explosion Fund.

Freemasonry.—*University of London Lodge, No. 2033.*—The usual spring meeting of this lodge was held at Freemasons' Hall on March 13th. In the absence of the Worshipful Master, Dr. Samuel Hague, the chair was occupied by Brother H. W. Kiallmark, P.G.D. Amongst those present were Dr. A. E. Sansom, Mr. R. A. Germaine, M.A. (Recorder of Lichfield), Mr. Beaumont Morice, LL.B. (Recorder of Hythe), Dr. A. W. Burrell, and Mr. F. E. Lemon, M.A., treasurer. The secretary of the Chère Reine Lodge was a guest. The Permanent Committee brought up a proposal whereby busy members might be enabled to keep their names on the books without being expected to attend the meetings so regularly as those desiring to go forward and to take up office in the usual way. As this lodge numbers amongst its members a considerable number of graduates whose engagements are numerous and increasing and who yet do not wish their connexion with the lodge to be severed, this amendment of by-laws, if adopted, is likely to prove useful. A general feeling was expressed that the lodge has now assumed such a degree of importance that a petition should be sent to the University asking that its periodical meetings should be noted on the agenda published in the *University Gazette.*

Irish Medical Schools' and Graduates' Association.—The annual general meeting of the above association was held on March 17th (St. Patrick's Day) at the Hotel Cecil, London, when the out-going President, Dr. William Alexander (Liverpool) resigned the chair to Sir Philip C. Smyly (Dublin). There was a very large attendance of members. A vote of condolence with the relatives of the late Sir William MacCormac, a foundation member and former president of the association, was passed. The members and their guests, to the number of 257, subsequently sat down to dinner under the chairmanship of Sir Philip Crampton Smyly, the guests of the evening being Lord Rathmore, Sir John Edge, and Dr. Brendan MacCarthy. Dr. Brendan MacCarthy was introduced to the President by Mr. P. J. Freyer and was presented with the Arnott Memorial Medal founded by Mr. David Arnott in memory of his father, the late Sir John Arnott. Dr. MacCarthy in the autumn of last year joined the late Mr. William Smyth in attending the typhus patients during the epidemic in the island of Arranmore on the coast of Western Donegal. The only boat that these two medical men could get to convey the sick from the island sank after they reached the main land because of its unseaworthiness. Dr. MacCarthy said that if it had not been for the tragic way in which Mr. Smyth died he did not think that anything would have been heard of the matter. "Our Defenders" was proposed by Dr. W. E. St. Lawrence Finny and was responded to by Inspector-General W. H. Lloyd, R.N., Brigade-Surgeon W. Ffolliott, and Surgeon-Major J. J. de Zouche Marshall, A.M.R. Dr. T. Gilbart Smith gave the toast of "Our Guests," to which Lord Rathmore replied in an eloquent speech in which he referred in feeling terms to the late Sir William MacCormac and the late Sir Richard Quain. Sir John Edge also responded to the toast and Sir William Broadbent having proposed the toast of "Ourselves" was followed by the President whose short speech concluded the evening. The singing of Miss Kate Rooney was much admired and Surgeon Major Marshall's songs were enthusiastically received.

# Parliamentary Intelligence.

## NOTES ON CURRENT TOPICS

### *Laundries and Factory Legislation*

THE Bill introduced into the House of Lords by the Earl of Lytton to bring laundries within the scope of certain of the provisions of our factory legislation is making substantial progress in that chamber. During the committee stage the Government proposed no amendments, but Lord Belper, speaking on their behalf, intimated that the Home Secretary was making inquiries into certain points and that as a result *amendments might be moved by the Government when the Bill reached* the House of Commons.

### *Midwives Bill*

Very few alterations of substance were made in the Midwives Bill *during its passage through the Grand Committee on Law*. The Bill remains a measure to protect the title of midwife and provides no penalty for women who may practise without having been certified. There is no change in the constitution of the proposed central Midwives Board but words have been inserted to secure that before the Privy Council approves of any rules framed by the Board it shall submit them to the General Medical Council and take into consideration any representations made by the latter body. By way of compromise on the question of an annual issue of certificates the promoters of the Bill agreed to the insertion of a provision which makes it necessary *for a certified woman to give notice in the month of* January of each year to the local supervising authority that she continues in practice in the area of the authority. Another change is that the maximum fee for certification has been raised from 10*s.* to one guinea, while in one of the early clauses words have been introduced saying that only certified midwives shall be entitled to recover professional fees in a court of law.

## HOUSE OF COMMONS

### THURSDAY, MARCH 13TH

### *The Conscientious Objector*

Mr. FORSTER asked the President of the Local Government Board if he would state the number of urban sanitary authorities in the United Kingdom from which he had received resolutions advocating the repeal of Clause 2 of the Vaccination Act of 1898 relating to the conscientious objector, and what steps, if any, he proposed to take to carry out the policy advocated by them.—Mr. LONG replied: I have received resolutions of this nature from 251 urban sanitary authorities. The Vaccination Act, 1898, will expire at the end of 1903 and the question of its renewal will have to be considered next year. In the meantime I do not propose to take any steps *for the repeal of the section* referred to.

### *Small-pox Epidemic at Dartford*

Sir WILLIAM HART DYKE asked the President of the Local Government Board whether he was aware that in the town of Dartford and surrounding villages and district the small-pox was spreading with great rapidity, whether he was aware that about 2000 workmen had been lately employed upon new buildings of the small-pox hospital near Dartford, and that the said workmen were lodging in Dartford and the neighbouring villages and causing thereby the spread of the disease in all directions, whether steps could be taken to secure accommodation for these workmen upon the spot where *they worked and thus arrest the danger of contagion*, and whether any and what communications had taken place between the *Local Government Board* and the Asylums Board on this subject.—Mr. LONG replied that he was aware that there had been numerous cases of small-pox in the localities referred to. It was a fact that about 2000 workmen were being employed upon new buildings at the small-pox hospital near Dartford. Some of these men were lodging in Dartford and the neighbouring villages, but a large proportion of them slept in huts built for them on the site. It was not expected that all would avail themselves of this accommodation, and if it were made compulsory for the men to live on the site it was probable that they would leave their work. It was most important that the buildings should be completed as soon as possible. He had been in communication with the managers of the *Metropolitan Asylums District* on this subject and he was pressing upon them to use every effort to secure that the workmen were accommodated on the site as far as practicable. He might add that every facility for vaccination was afforded to the workmen and that as regards those employed nearest to buildings containing cases of small-pox they were some time since required to be vaccinated.

Sir WILLIAM HART DYKE asked the right hon. gentleman whether he was aware that a very large number of these workmen after their week's work at this hospital were in the habit of travelling to London by train and returning by train to their work on the following Monday morning, and whether in view of the great risk this caused, not only with regard to the railway carriages, he did not see the absolute necessity of securing the detention of these workmen and their accommodation on the spot.—Mr. LONG said that he quite agreed that this was a very serious matter indeed, but he had no power to secure the detention of these men on the spot and, indeed, it was impossible to provide for them on the spot. It was true that it was most important to prevent any risk of the spread of the disease outside the metropolitan area, but it was more important still that provision should be made as rapidly as possible for the reception of cases within the metropolitan area. *If that was not done the risk of the spread of the disease would* be even greater than it was at present. Every effort had been made to provide for these workmen on the spot and to secure their revaccination. If people in the district concerned would only take the precaution of being revaccinated the risk would be largely diminished.

Mr. BAYLEY asked whether the provision of another hospital ship would not lessen the risk.—Mr. LONG replied that it would not in the smallest degree. It would be impossible to provide another hospital ship in time to take the place of the building accommodation now being provided. The Metropolitan Asylums Board was trying to double its supply of beds by buildings now being erected.

### FRIDAY, MARCH 14TH

### *The Ventilation of the House*

Mr. WYLIE in the course of debate called attention to the imperfect ventilation and other sanitary arrangements of some parts of the House of Commons building and to the expediency of putting electric ventilating fans into every lobby, passage, room, and apartment where practicable, and suggested that a committee of experts should be appointed to inquire into the whole question of ventilation and sanitation of the building. The hon. member declared that the existing system of ventilation was antiquated and unsatisfactory.—Mr. AKERS DOUGLAS, First Commissioner of Works, who has charge of the building, said that the present system of ventilation had been approved by *various committees in recent years, but he was prepared to have* another committee appointed, and he would consider whether it should be a committee of experts or a committee of Members of the House. Samples of the atmosphere, he said, had been taken and were now in process of analysis.

### MONDAY, MARCH 17TH

### *Enteric Fever in South Africa*

Sir WALTER FOSTER asked the Secretary of State for War whether he was aware that when Lord Roberts was in command in South Africa all cases of enteric fever among the troops as well as those occurring amongst civilians were notified to the health office at Pretoria, and that after the departure of Lord Roberts notification of cases amongst the soldiers was stopped, and what were the reasons that led to the cessation of the system of notification which was recognised as an essential part of sanitary administration.—Mr. BRODRICK said: This notification was carried out for a brief period but it was held that the notification of every case of enteric fever in a country where the disease is endemic was unnecessary and that intercommunication of any outbreak of infectious diseases between the health officer and the principal medical officer was sufficient.—Sir WALTER FOSTER asked the Secretary of State for War whether any special sanitary officers had been appointed to inquire into the origin and spread of enteric fever and other preventable diseases among the troops in South Africa, to inspect the localities in which such diseases were most prevalent, and to advise with regard to their prevention.—Mr. BRODRICK replied: Yes, special sanitary officers have been sent out to South Africa.

### *Water in Butter*

Mr. HANBURY, in reply to a question on this subject, said that he would draw up the new regulations as strictly as he could with a view to prevent the sale of milk-blended butter containing water above the standard fixed by him.

### *Cancer Research*

Mr. WEIR asked the First Lord of the Treasury, in view of the action taken by foreign Governments in the matter of research into the cause, cure, and prevention of cancer, was the Government now prepared to consider the advisability *of the appointment of a commission for the* purpose of determining how research respecting this disease could best be stimulated?—Mr. ARTHUR LEE asked the right hon. gentleman if he could now state whether the Government was prepared to extend financial assistance to the forthcoming inquiry into the causes and cure of cancer.—Mr. BALFOUR said: My view remains that this subject, important as it is, can best be dealt with by private though not unorganised enterprise. I am told that the Royal College of Physicians of London and the Royal College of Surgeons of England have appointed a joint committee to consider how an investigation into the possible cure of cancer can best be carried out and I have received communications from the President of the Royal College of Physicians of London and from other quarters which led me to believe that their efforts will be successful and that the scientific staff which they have at their command and the liberality of the public will enable a really important scientific investigation into this subject to be undertaken and carried through. In these circumstances I think it would be unwise for the Government to intervene in a matter which after all Governments are not able to conduct with very great success from a scientific or public point of view.

## MIDWIVES BILL

### PROCEEDINGS IN THE GRAND COMMITTEE

The *Grand Committee* of the House of Commons on Law met again on March 14th, with Sir JAMES FERGUSSON in the chair, and completed the consideration of the Midwives Bill.

The fourth clause of the Bill as it came before the committee was in these terms—viz.: "On the passing of this Act the Lord President of the Council shall take steps to secure the formation of a Central Midwives Board, which shall consist of (1) four registered medical practitioners, one to be appointed by the Royal College of Physicians of London, one by the Royal College of Surgeons of England, one by the Society of Apothecaries and one by the Incorporated Midwives Institute; (2) two persons (one of whom shall be a woman) to

two to Mrs. Evans's Home at Solihull. In some cases railway fares have been paid to enable patients to go into the country, or towards their expenses in boarding at farm houses. Surgical appliances have been supplied and in some instances patients have been relieved at their own homes for many consecutive weeks with milk, groceries, coal, or meat. During the past year the patients and their friends have contributed £7 15*s.* 2*d.* towards expenses.

**The Liverpool School of Tropical Medicine.**—The report of the Liverpool School of Tropical Medicine for 1901, being the third year of the existence of the school, shows that steady progress has been made in the work during the past year. The hospital report states that four nurses were trained in 1901 at the expense of the school in the special tropical ward of the Royal Southern Hospital. Three of these nurses were sent by the Colonial Nursing Association of London. In connexion with the hospital a special department for out-patients suffering from tropical diseases was opened in October last which will be of great value to the school. During the year 131 cases were treated. Financial support has been freely forthcoming from those interested in the work of the school, but its operations entail a very large annual expenditure and as the school is not endowed it is to be hoped that liberal support will continue to be given.

**British Laryngological, Rhinological, and Otological Association.**—Under the chairmanship of their President, Dr. J. Macintyre of Glasgow, the members of the British Laryngological, Rhinological, and Otological Association held their annual dinner on March 14th at the Café Royal, Regent-street, London. Dr. C. O. Hawthorne proposed the toast of "The Association," and said that in the wide field of medicine general practitioners were debtors to the association for distinct contributions to their knowledge and their capacity to deal with suffering humanity. The President proposed the toast of "The Guests," which was responded to by Sir William Dunn, M.P., and Mr. Wilhelm Ganz. Dr. R. H. Woods of Dublin assisted in the entertainment of the guests by a humorous recitation and Dr. R. A. D. Daniel contributed some humorous songs. The music provided by Mr. Wilhelm Ganz, with the assistance of Sénor Guetary and Mr. Mervyn Dene, was highly appreciated.

**Royal Institution.**—The following are the lecture arrangements at the Royal Institution after Easter:—Dr. Allan Macfadyen, three lectures on Recent Methods and Results in Biological Inquiry; Professor F. York Powell, three lectures on English Kings and Kingship; Professor Karl Pearson, three lectures on the Laws of Heredity, with Special Reference to Man (the Tyndall Lectures); Professor Dewar, three lectures on the Oxygen Group of Elements; Dr. A. Smith Woodward, three lectures on Recent Geological Discoveries; Mr. M. H. Spielmann, three lectures on Contemporary British Sculpture; Mr. W. H. Cummings, three lectures on British National Song (with musical illustrations); Professor Walter Raleigh, three lectures on Poets and Poetry: and Professor Brander Matthews, three lectures on the Development of the English Drama: (1) the Art of the Dramatist, (2) the Drama of the Middle Ages, and (3) the Drama under Elizabeth. The Friday evening meetings will commence on April 11th when Professor Dewar will deliver a discourse on Problems of the Atmosphere. Succeeding Friday evening discourses will be delivered by Sir John H. A. Macdonald, Dr. J. Mackenzie Davidson, Sir Robert Ball, Sir Benjamin Baker, Professor A. E. Tutton, and other gentlemen.—Magnetism in Transitu formed the subject of the Friday evening discourse delivered on March 14th by Professor Silvanus Thompson. The subject was illustrated not only by diagrams, models, and numerous experiments, but also by pictures projected by means of the animatograph, in which diagrams of lines in motion represented the formation, growth, and disappearance of magnetic lines of force. One of the experiments was of a remarkable nature. Faraday showed long ago that when an electric current was passed through a wire an induced current was created in a second wire parallel to, but insulated from, the first one. The currents in the two wires travelled in opposite directions. Professor Thompson found that the magnetic lines of force existing between the two wires could be twisted in space by passing one wire through one loop and the other wire through the other loop of a figure-of-8 made of thin iron rod. The primary and the induced currents then travelled in the same direction. A series of 20 such figures-of-8, each so made that the metal composing it did not touch at the point of crossing, was fixed edgeways on a board about two feet long, all of them separate and similarly situated; the straight primary wire passed through one row of loops and the secondary wire through the other row.

**Chesterfield Hospital.**—The annual meeting of the governors of, and subscribers to, the Chesterfield Hospital, was held on March 13th. The report stated that during the year 420 persons were admitted, being 10 less than in 1900. The total number treated was 462. Of the 42 patients in the hospital at the end of 1900, 33 were discharged cured, six were relieved, and three were discharged at their own request. Of those admitted in 1901, 315 were discharged cured, 19 were relieved, 38 died, and 48 remained under treatment. The average stay of each patient was 33·92 days, against 28·63 days in 1900. In the out-patient department 2076 persons received benefit, as compared with 1858. There were 1211 casualties dealt with. The total expenditure for the year, exclusive of extraordinary expenditure, was £3421 13*s.* 4*d.* This exceeds the amount of any previous year owing to the number of patients. The extraordinary expenditure amounted to £752, and was incurred in connexion with the sanitary and heating arrangements. The report having been adopted the chairman announced that a gift of £2240 had been received from the trustees of the Renishaw Park Colliery Explosion Fund.

**Freemasonry.**—*University of London Lodge, No. 2033.*—The usual spring meeting of this lodge was held at Freemasons' Hall on March 13th. In the absence of the Worshipful Master, Dr. Samuel Hague, the chair was occupied by Brother H. W. Kiallmark, P.G.D. Amongst those present were Dr. A. E. Sansom, Mr. R. A. Germaine, M.A. (Recorder of Lichfield), Mr. Beaumont Morice, LL.B. (Recorder of Hythe), Dr. A. W. Burrell, and Mr. F. E. Lemon, M.A., treasurer. The secretary of the Chère Reine Lodge was a guest. The Permanent Committee brought up a proposal whereby busy members might be enabled to keep their names on the books without being expected to attend the meetings so regularly as those desiring to go forward and to take up office in the usual way. As this lodge numbers amongst its members a considerable number of graduates whose engagements are numerous and increasing and who yet do not wish their connexion with the lodge to be severed, this amendment of by-laws, if adopted, is likely to prove useful. A general feeling was expressed that the lodge has now assumed such a degree of importance that a petition should be sent to the University asking that its periodical meetings should be noted on the agenda published in the *University Gazette.*

**Irish Medical Schools' and Graduates' Association.**—The annual general meeting of the above association was held on March 17th (St. Patrick's Day) at the Hotel Cecil, London, when the out-going President, Dr. William Alexander (Liverpool) resigned the chair to Sir Philip C. Smyly (Dublin). There was a very large attendance of members. A vote of condolence with the relatives of the late Sir William MacCormac, a foundation member and former president of the association, was passed. The members and their guests, to the number of 257, subsequently sat down to dinner under the chairmanship of Sir Philip Crampton Smyly, the guests of the evening being Lord Rathmore, Sir John Edge, and Dr. Brendan MacCarthy. Dr. Brendan MacCarthy was introduced to the President by Mr. P. J. Freyer and was presented with the Arnott Memorial Medal founded by Mr. David Arnott in memory of his father, the late Sir John Arnott. Dr. MacCarthy in the autumn of last year joined the late Mr. William Smyth in attending the typhus patients during the epidemic in the island of Arranmore on the coast of Western Donegal. The only boat that these two medical men could get to convey the sick from the island sank after they reached the main land because of its unseaworthiness. Dr. MacCarthy said that if it had not been for the tragic way in which Mr. Smyth died he did not think that anything would have been heard of the matter. "Our Defenders" was proposed by Dr. W. E. St. Lawrence Finny and was responded to by Inspector-General W. H. Lloyd, R.N., Brigade-Surgeon W. Ffolliott, and Surgeon-Major J. J. de Zouche Marshall, A.M.R. Dr. T. Gilbart Smith gave the toast of "Our Guests," to which Lord Rathmore replied in an eloquent speech in which he referred in feeling terms to the late Sir William MacCormac and the late Sir Richard Quain Sir John Edge also responded to the toast and Sir William Broadbent having proposed the toast of "Ourselves" was followed by the President whose short speech concluded the evening The singing of Miss Kate Rooney was much admired and Surgeon Major Marshall's songs were enthusiastically received

## NOTES ON CURRENT TOPICS

### *Laundries and Factory Legislation*

THE Bill introduced into the House of Lords by the Earl of Lytton to bring laundries within the scope of certain of the provisions of our factory legislation is making substantial progress in that chamber During the committee stage the Government proposed no amendments but Lord Belper, speaking on their behalf intimated that the Home Secretary was making inquiries into certain points and that as a result amendments might be moved by the Government when the Bill reached the House of Commons

### *Midwives Bill*

Very few alterations of substance were made in the Midwives Bill during its passage through the Grand Committee on Law The Bill remains a measure to protect the title of midwife and provides no penalty for women who may practise without having been certified There is no change in the constitution of the proposed central Midwives Board but words have been inserted to secure that before the Privy Council approves of any rules framed by the Board it shall submit them to the General Medical Council and take into consideration any representations made by the latter body By way of compromise on the question of an annual issue of certificates the promoters of the Bill agreed to the insertion of a provision which makes it necessary for a certified woman to give notice in the month of January of each year to the local supervising authority that she continues in practice in the area of the authority Another change is that the maximum fee for certification has been raised from 10s to one guinea, while in one of the early clauses words have been introduced saying that only certified midwives shall be entitled to recover professional fees in a court of law

## HOUSE OF COMMONS

### THURSDAY, MARCH 13TH

### *The Conscientious Objector*

Mr FORSTER asked the President of the Local Government Board if he would state the number of urban sanitary authorities in the United Kingdom from which he had received resolutions advocating the repeal of Clause 2 of the Vaccination Act of 1898 relating to the conscientious objector and what steps if any he proposed to take to carry out the policy advocated by them —Mr LONG replied: I have received resolutions of this nature from 251 urban sanitary authorities The Vaccination Act 1898 will expire at the end of 1903 and the question of its renewal will have to be considered next year In the meantime I do not propose to take any steps for the repeal of the section referred to

### *Small pox Epidemic at Dartford*

Sir WILLIAM HART DYKE asked the President of the Local Government Board whether he was aware that in the town of Dartford and surrounding villages and district the small pox was spreading with great rapidity, whether he was aware that about 2000 workmen had been lately employed upon new buildings of the small pox hospital near Dartford, and that the said workmen were lodging in Dartford and the neighbouring villages and causing thereby the spread of the disease in all directions, whether steps could be taken to secure accommodation for these workmen upon the spot where they worked and thus arrest the danger of contagion, and whether any and what communications had taken place between the Local Government Board and the Asylums Board on this subject —Mr LONG replied that he was aware that there had been numerous cases of small pox in the localities referred to It was a fact that about 2000 workmen were being employed upon new buildings at the small pox hospital near Dartford Some of these men were lodging in Dartford and the neighbouring villages but a large proportion of them slept in huts built for them on the site It was not expected that all would avail themselves of this accommodation and if it were made compulsory for the men to live on the site it was probable that they would leave their work It was most important that the buildings should be completed as soon as possible He had been in communication with the managers of the Metropolitan Asylums District on this subject and he was pressing upon them to use every effort to secure that the workmen were accommodated on the site as far as practicable He might add that every facility for vaccination was afforded to the workmen and that as regards those employed nearest to buildings containing cases of small pox they were some time since required to be vaccinated

Sir WILLIAM HART DYKE asked the right hon gentleman whether he was aware that a very large number of these workmen after their week's work at this hospital were in the habit of travelling to London by train and returning by train to their work on the following Monday morning, and whether in view of the great risk this caused, not only with regard to the railway carriages he did not see the absolute necessity of securing the detention of these workmen and their accommodation on the spot —Mr LONG said that he quite agreed that this was a very serious matter indeed, but he had no power to secure the detention of these men on the spot and indeed it was impossible to provide for them on the spot It was true that it was most important to prevent any risk of the spread of the disease outside the metropolitan area but it was more important still that provision should be made as rapidly as possible for the reception of cases within the metropolitan area If that was not done the risk of the spread of the disease would be even greater than it was at present Every effort had been made to provide for these workmen on the spot and to secure their revaccination If people in the district concerned would only take the precaution of being revaccinated the risk would be largely diminished

Mr BAYLEY asked whether the provision of another hospital ship would not lessen the risk —Mr LONG replied that it would not in the smallest degree It would be impossible to provide another hospital ship in time to take the place of the building accommodation now being provided The Metropolitan Asylums Board was trying to double its supply of beds by buildings now being erected

### FRIDAY, MARCH 14TH

### *The Ventilation of the House*

Mr WYLIE in the course of debate called attention to the imperfect ventilation and other sanitary arrangements of some parts of the House of Commons building and to the expediency of putting electric ventilating fans into every lobby passage, room, and apartment where practicable, and suggested that a committee of experts should be appointed to inquire into the whole question of ventilation and sanitation of the building The hon member declared that the existing system of ventilation was antiquated and unsatisfactory —Mr AKERS DOUGLAS First Commissioner of Works who has charge of the building, said that the present system of ventilation had been approved by various committees in recent years, but he was prepared to have another committee appointed and he would consider whether it should be a committee of experts or a committee of Members of the House Samples of the atmosphere, he said had been taken and were now in process of analysis

### MONDAY, MARCH 17TH

### *Enteric Fever in South Africa*

Sir WALTER FOSTER asked the Secretary of State for War whether he was aware that when Lord Roberts was in command in South Africa all cases of enteric fever among the troops as well as those occurring amongst civilians were notified to the health office at Pretoria, and that after the departure of Lord Roberts notification of cases amongst the soldiers was stopped and what were the reasons that led to the cessation of the system of notification which was recognised as an essential part of sanitary administration —Mr BRODRICK said: This notification was carried out for a brief period but it was held that the notification of every case of enteric fever in a country where the disease is endemic was unnecessary and that intercommunication of any outbreak of infectious diseases between the health officer and the principal medical officer was sufficient —Sir WALTER FOSTER asked the Secretary of State for War whether any special sanitary officers had been appointed to inquire into the origin and spread of enteric fever and other preventable diseases among the troops in South Africa to inspect the localities in which such diseases were most prevalent and to advise with regard to their prevention —Mr BRODRICK replied Yes special sanitary officers have been sent out to South Africa

### *Water in Butter*

Mr HANBURY in reply to a question on this subject, said that he would draw up the new regulations as strictly as he could with a view to prevent the sale of milk blended butter containing water above the standard fixed by him

### *Cancer Research*

Mr WEIR asked the First Lord of the Treasury in view of the action taken by foreign Governments in the matter of research into the cause, cure, and prevention of cancer was the Government now prepared to consider the advisability of the appointment of a commission for the purpose of determining how research respecting this disease could best be stimulated?—Mr ARTHUR LEE asked the right hon gentleman if he could now state whether the Government was prepared to extend financial assistance to the forthcoming inquiry into the causes and cure of cancer —Mr BALFOUR said: My view remains that this subject important as it is can best be dealt with by private though not unorganised enterprise I am told that the Royal College of Physicians of London and the Royal College of Surgeons of England have appointed a joint committee to consider how an investigation into the possible cure of cancer can best be carried out and I have received communications from the President of the Royal College of Physicians of London and from other quarters which led me to believe that their efforts will be successful and that the scientific staff which they have at their command and the liberality of the public will enable a really important scientific investigation into this subject to be undertaken and carried through In these circumstances I think it would be unwise for the Government to intervene in a matter which, after all Governments are not able to conduct with very great success from a scientific or public point of view

## MIDWIVES BILL

### PROCEEDINGS IN THE GRAND COMMITTEE

The Grand Committee of the House of Commons on Law met again on March 14th with Sir JAMES FERGUSSON in the chair, and completed the consideration of the Midwives Bill

The fourth clause of the Bill as it came before the committee was in these terms—viz: "On the passing of this Act the Lord President of the Council shall take steps to secure the formation of a Central Midwives Board, which shall consist of (1) four registered medical practitioners one to be appointed by the Royal College of Physicians of London, one by the Royal College of Surgeons of England one by the Society of Apothecaries and one by the Incorporated Midwives Institute) (2) two persons (one of whom shall be a woman) to be appointed for terms of *three years* by the Lord President of the Council; and (3) one person to be appointed for a term *of three years* by the Association of County Councils. After *two years* from the commencement of this Act the members appointed under subsection (1) shall retire, but shall be eligible for reappointment annually. Any vacancy occurring by resignation or death shall be filled up in the case of a member appointed under subsections (1) and (3) by the body which appointed him, and in the case of a member appointed under subsection (2) by the Lord President of the Council. The duties and powers of the Board shall be as follows: I. To frame rules (subject to the approval of the Privy Council after consultation with the General Medical Council) (*a*) regulating the issue of certificates and the conditions of admission to the roll of midwives; (*b*) regulating the course of training and the conduct of examinations; *(c) regulating the admission to the roll of women already* in practice as midwives at the passing of this Act; (*d*) regulating, supervising, and restricting within due limits the practice of midwives; (*e*) deciding the conditions under which midwives may be suspended from practice; and (*f*) defining the particulars required to be given in any notice under Section 10 of this Act. II. To appoint examiners. III. To decide upon the places where, and the times when, examinations shall be held. IV. To publish annually a roll of midwives who have been duly certified under this Act. V. To decide upon the removal from the roll of the name of any midwife for disobeying the rules and regulations from time to time laid down under this Act by the Central Midwives Board, or for other misconduct, and also to decide upon the restoration to the roll of the name of any midwife so removed. VI. To issue certificates; and generally to do any other act or duty which may be necessary for the due and proper carrying out of the provisions of this Act."

Sir **FRANCIS POWELL** moved to amend the first sentence of the clause by substituting "the General Medical Council" for "the Lord President of the Council." He pointed out that the General Medical Council appeared in this connexion in the Bill of 1900, and he argued that it was the fitter body to undertake the formation of the proposed Central Midwives Board.

Mr. **HEYWOOD JOHNSTONE** said that all that was required of the Lord President of the Council in this connexion was to secure the formation of the Board whose component elements were set out in the Bill. All his lordship would have to do would be to see that a few letters were written.

Mr. **JESSE COLLINGS**, *Under Secretary of State for Home Affairs*, after reminding the committee that the Privy Council was recommended by the Select Committee of 1893, submitted that the proposed work ought to be in the hands of a Government department and not in those of a private corporation or body, however eminent. The Central Midwives Board would practically have the power of levying taxation upon the local authorities, because the expenses of the Board so far as they were not provided for by the fees were to be levied upon the local authorities. And if they must have a Government department there could be no Government department more suitable than the Privy Council which already had charge of the administration of the Medical Acts.

Sir **WALTER FOSTER** said that it was a great pity that the committee were without a representative of the Privy Council, because nobody ever expressed a stronger opinion upon this point than the Lord President himself. In 1898, when the Lord President received a deputation of the promoters of the Bill, he said that the only form in which the measure would be acceptable would be if the Midwives Board were placed under the General Medical Council. He said that it was extremely desirable that before another Bill was introduced the promoters should come to some definite understanding with the medical profession as represented by the General Medical Council. The result of this statement was that when the Bill was brought in in 1900 the clause now under consideration read that the President of the General Medical Council should take steps to secure the formation of a Central Midwives Board.

Mr. **HEYWOOD JOHNSTONE**: The promoters of the Bill were invited to amend it in this direction.

Sir **WALTER FOSTER** said that he would like to hear some explanation on the point from the Privy Council itself. The General Medical Council was not a private body but a public body created by statute, working under the Privy Council and responsible to the Privy Council.

Mr. **JESSE COLLINGS**: The General Medical Council has *no powers to* tax local authorities.

Sir **WALTER FOSTER** asked why, if the General Medical Council had no powers to tax local authorities, should the proposed Central Midwives Board be entrusted with them? He thought that such powers would be much safer in the hands of the General Medical Council than in those of this Board. Not only so, but he thought that if this matter were entrusted to the General Medical Council it would contribute to the smooth working of the whole measure.

Mr. **VICARY GIBBS** spoke in support of the clause as it stood.

Sir **JOHN BATTY TUKE** said that as a member of the General Medical Council he spoke with some diffidence on this matter, but he could not help thinking that the powers proposed for this Board were powers which could only be exercised by a medical body. The education and examination of midwives *involved such purely* medical considerations that he could not understand how the Privy Council could undertake them. It would come to this—that the whole matter would be handed over to the medical adviser of the Privy Council, who would be the *only person whose opinion would be taken.*

Mr. **JESSE COLLINGS** said that it was not altogether a medical question, but in any case the fact that the Privy Council was over the General Medical Council in the matter of the Medical Acts would not place the Privy Council over the General Medical Council in regard to this Act. The promoters of the Bill had, he thought, gone as far as they possibly could when they gave the General Medical Council a statutory right to be consulted by the Privy Council.

Mr. **COHEN**, speaking with all respect for the General Medical Council, could not regard it as the proper body to see to the formation of the proposed Board.

Mr. **LEES KNOWLES** said that if the General Medical Council were accepted *as the authority all Parliamentary* control would be lost.

Mr. **JOHN BURNS** considered it most important that Members of the House of Commons should be able to discuss the action of the proposed Board in Committee of Supply on the vote for the salary of the Lord President of the Privy Council.

The amendment of Sir Francis Powell was negatived without a division.

Mr. **ROBERT AMBROSE** moved an amendment to the effect that the Board should consist of "seven registered medical practitioners *nominated by the General Medical Council. After two years from the* passing of this Act one-half of the six members of the Board selected by the General Medical Council shall retire, but shall be eligible for re-election, and thereafter one half of such members of the Board shall retire annually in such manner that each of such members shall serve a term of two years before retiring, and members so retiring shall be eligible for re-election. In the event of the death or resignation of a member of the Board the successor elected or appointed shall hold office for the remaining period for which the deceased or resigned member was elected, and must be qualified equally with such deceased or resigned member to hold office as a member of the Board, and shall, on retiring, be eligible for re-election. No member of the Board shall *act as teacher, instructor or examiner of midwives, and no member of* the Board shall take any part in any inquiry respecting the conduct of any midwife to whom he had acted as teacher or instructor."

Mr. **HEYWOOD JOHNSTONE** *said that the committee had just decided* that the General Medical Council should not have the duty and responsibility of forming the Board and now the committee was asked to say that the President of the Privy Council should have his hands tied and have a Board ready made for him on the nomination of the General Medical Council. The substantial point, however, was whether this Central Midwives Board should be composed entirely of medical men or whether there should be laymen on it. As the Bill stood there must be a majority of registered medical practitioners on the Board. Of the seven members four must be registered medical practitioners and there was nothing to say that the other three might not be registered medical practitioners.

Mr. **T. P. O'CONNOR** said he did not think that the Board should be entirely a medical board. There might be taxation and if there was there must be representation and therefore he approved of the representation of the county councils. At the *same time he thought the* medical element should predominate.

Sir **WALTER FOSTER** agreed that four registered medical practitioners were enough, but he thought that there should be more ladies on the *Board than was proposed.*

*After some further discussion* Mr. **AMBROSE** agreed to withdraw his amendment.

Mr. **T. P. O'CONNOR** then moved to delete from the clause the references to the Royal College of Physicians of London, the Royal College of Surgeons of England, the Society of Apothecaries, and the Incorporated Midwives Institute, and to make the clause read, "Four registered medical practitioners to be nominated by the General Medical Council, each of whom shall be holding the appointment of teacher of midwifery at a recognised medical school in England, or who shall have previously held such an appointment." The General Medical Council he said, was representative of the whole medical profession, and was, in his opinion, entitled to this nomination.

Mr. **HEYWOOD JOHNSTONE** said that the real objection here was to the Incorporated Midwives Institute. He thought that the committee would thoroughly *realise that a Board of this sort ought to have upon* it some representative of the governed as well as the governors; that there ought to be some person upon it able to speak for and represent those who were to be put under the authority of the Board and subject to the rules framed by it. That was of itself a sufficient reason for including the Incorporated Midwives Institute. He regretted to say that during the second-reading debate he made an erroneous statement with reference to the institute. It was not incorporated by royal charter, but was incorporated under the Companies Act by special licence *from the Board of Trade as a limited* company not carrying on business for the purposes of profit and therefore entitled to call itself "incorporated" without the addition of "Limited" to its name. It was originally founded in 1881 and incorporated in 1889, the objects of the body as stated in the memorandum of incorporation being to raise the efficiency and to improve the status of midwives, to petition Parliament for *their recognition, and to provide for the* examination and the granting of certificates of qualification to midwives. The institute was the only representative body of midwives in the whole kingdom, and he submitted that it was well entitled to have the appointment of *one of the registered medical practitioners* to the Central Midwives Board.

Sir **WALTER FOSTER** said that his hon. friend was not quite fair in saying that the inwardness of this amendment was to strike a blow at *the Incorporated* Midwives Institute. That was not the motive in his mind or in the mind of the mover of the amendment. The medical profession in looking over this Bill were very anxious that this clause should be modified in the direction of giving the ordinary medical practitioner more control over the constitution of this Board. With regard to the two Royal Colleges it had been suggested to him that if they were to be left in the clause the election should be in the hands of the Members of the Colleges. Each of these bodies was at present governed by a comparatively small Council—a Council which was practically self-elected and therefore *it did not command the confidence* of the whole body of the Members. Now the General Medical Council was representative more or less of the whole profession—not so representative as it might be, but it had certain Direct Representatives who were elected by the whole body of the registered practitioners. Therefore, he thought that the right thing would be to give the *appointment of these four practitioners, or three* of them at any rate, to the General Medical Council. He did not want to bring the Incorporated Midwives Institute into the question at all and he would exclude it, and say that the General Medical Council should appoint three out of the four medical practitioners, one of the three to be a woman.

Mr. **LAWRENCE** said that he was satisfied about the Incorporated Midwives Institute, but he would like to hear something about the other three bodies, and especially the Apothecaries' Society.

Mr. **GEORGE HARWOOD** spoke in favour of the recognition in this connexion of the General Medical Council.

Mr. **O'CONNOR** disclaimed *the idea of his amendment being* directed against the Incorporated Midwives Institute. If he had his choice between the institute and the Apothecaries' Society he would give all his support to the former body, because he recognised the force of the statement that it represented the governed body.

The **CHAIRMAN** then put the question that the words "one to be appointed by the Royal College of Physicians of London" stand part of the clause.

This question was answered in the affirmative by a majority of 24 against 7 votes

Mr T P O Connor then said he would be prepared to move the omission of the name of the Apothecaries Society and the substitution of the General Medical Council if he thought the latter body would accept the duty of appointing one of the four registered medical practitioners

Sir John Batty Tuke They would not accept it

Mr O Connor said that in these circumstances he would move to delete the name of the Apothecaries Society in order to substitute that of the Royal British Nurses Association This body he said was the most representative body of the women engaged in nursing in this country

Mr Heywood Johnstone asked whether the hon Member could refer to any reference to midwives in the charter of the Royal British Nurses Association

Mr O Connor said that he knew that a very considerable number of the nurses of the association were trained in midwifery and that the association had a list of members who had obtained certificates qualifying them to act as midwives

Mr Schwann said that out of 2800 nurses who were members of the association 254 had been trained as midwives

Mr O Connor insisted on urging the claims of the association the hostility to which he could not understand

Mr Heywood Johnstone assured the hon Member that he had nothing to say against the association which was in his opinion a very deserving body As a matter of fact however midwifery was really no essential part of the training of the association Moreover, the hon Member had not shown that the association had any desire to be represented in this matter

Mr O Connor The president of the association is desirous that the body should be represented

Mr Heywood Johnstone said that the question had never been brought before the association as a whole As for the Apothecaries Society its name had always appeared in these Bills and had never before been challenged

Sir John Batty Tuke pointed out that the Apothecaries Society was not a mere trading body or pharmaceutical society, but one of the largest qualifying bodies in the three kingdoms

Mr John Burns added that the Society had interested itself in the midwives question as long ago as 1813

Sir Walter Foster speaking in support of the amendment said he doubted whether the total membership of the Incorporated Midwives Institute was more numerous than the nurses trained in midwifery on the list of the Royal British Nurses Association

Mr Schwann explained that the institute had 700 members

Mr O Connor thought that as the questions to be dealt with by the proposed Board would be largely questions of nursing the association should be represented in its constitution

Sir Michael Foster pointed out that the Bill dealt with midwives and not with nurses There was a tale in the medical profession as to the difference between physicians and surgeons The physicians always said that they were surgeons and something more A midwife was a nurse and something more and it was with regard to that something more that they were specially dealing in this Bill

The question was then put that the words one by the Society of Apothecaries stand part of the clause and it was answered in the affirmative by 23 votes against 5

Mr Ambrose moved to delete the Incorporated Midwives Institute in order to insert the name of the Victoria University He did so with the view of having the great manufacturing districts represented on the proposed Board

Sir Walter Foster agreed that the provinces should be represented in some way

Mr Emmott took the view that anything in the way of sectional representation of the universities would do more harm than good

The amendment was rejected by 24 votes against 3

Mr Griffith Boscawen who had not been present during the previous debate moved to give a representative to the Royal British Nurses Association

Mr O Connor intimated that he would vote for the amendment

Mr Heywood Johnstone asked the committee to reject it

On a division the amendment was rejected by 19 votes against 4

On the motion of Mr Heywood Johnstone it was agreed to give the Board power to cancel as well as to issue certificates and to add at the end of the section these words—viz 'Rules framed under this section shall be valid only if approved by the Privy Council, and the Privy Council before approving any such rules shall submit them to the General Medical Council and shall take into consideration any representations which that Council may make with respect thereto In moving the addition of these words the hon Member said that there must be a Government department in the background to give sanction to the rules but he hoped the words carried out the intention of the promoters of the Bill—to recognise the position of the General Medical Council and to show due deference to it by giving it a place in the Act and providing that it should be consulted

The words subject to the approval of the Privy Council after consultation with the General Medical Council were struck out of the clause

In Clause 5 dealing with fees and expenses Sir Walter Foster moved to substitute one guinea for 10s as the maximum fee to be charged to women on presenting themselves for certification He did so he said, with a view of lessening the burden likely to fall upon the rates His calculation was that they would require at least £2000 a year to carry on the work connected with the qualifying of these women and he did not think one guinea too much for them to pay for their certificate

Mr Jesse Collings pointed out that the sum mentioned in the Bill originally was one guinea and 10s had been substituted at the instance of the Home Office but he was quite willing to leave the matter to the decision of the committee

Mr Heywood Johnstone said that he was prepared to accept the amendment remarking that if in experience one guinea was found to be too high a fee steps could be taken to reduce it

The amendment was agreed to

In Clause 10 dealing with notification of practice it was agreed, on the motion of Mr Heywood Johnstone to insert words requiring the midwife to give notice to the local supervising authority in the month of January of every year during which she continues to practise within the area of the authority

Mr Griffith Boscawen moved to insert a new clause to provide that "any woman certified under this Act who shall undertake the charge of a case of abnormality or disease shall be liable upon summary conviction to a fine not exceeding £10

Mr Heywood Johnstone said that no woman undertook the charge of these cases because nobody could tell beforehand when a case was going to be abnormal or normal Moreover the practice of these women would be limited and restricted within due limits by the Central Midwives Board, and if the Board could solve a question which had not yet been solved and say whether a case would be abnormal or not no doubt it would do it One of the main objects of the Bill was to have a person in attendance who would know when to send for a medical man

Sir Walter Foster said that while nobody could tell beforehand whether a case was going to be natural or abnormal it was of the greatest importance that the strongest possible incentive should be given to women in attendance to send for qualified assistance the moment anything went wrong

Mr Jesse Collings said that this matter had been very carefully considered and he hoped the committee would not accept the proposed clause

On a division it was rejected by 22 votes against 4

This completed the consideration of the Bill and accordingly the Bill as amended was ordered for report to the House of Commons

Any vacancy occurring by resignation or death shall be filled up in the case of a member appointed under subsections (1) and (3) by the body which appointed him, and in the case of a member appointed under subsection (2) by the Lord President of the Council. The duties and powers of the Board shall be as follows: I. To frame rules (subject to the approval of the Privy Council after consultation with the General Medical Council) (*a*) regulating the issue of certificates and the conditions of admission to the roll of midwives; (*b*) regulating the course of training and the conduct of examinations; (c) regulating the admission to the roll of women already in practice as midwives *at the passing of this Act*; (*d*) *regulating*, supervising, and restricting within due limits the practice of midwives; (*e*) deciding the conditions under which midwives may be suspended from practice; and (*f*) defining the particulars required to be given in any notice under Section 10 of this Act. II. To appoint examiners. III. To decide upon the places where, and the times when, examinations shall be held. IV. To publish annually a roll of midwives who have been duly certified under this Act. V. To decide upon the removal from the roll of the name of any *midwife for disobeying* the rules and regulations from time to time laid down under this Act by the Central Midwives Board, or for other misconduct, and also to decide upon the restoration to the roll of the name of any midwife so removed. VI. To issue certificates; and generally to do any other act or duty which may be necessary for the due and proper carrying out of the provisions of this Act."

Sir FRANCIS POWELL moved to amend the first sentence of the clause by substituting "the General Medical Council" for "the Lord President *of the Council." He pointed out that the General Medical Council* appeared in this connexion in the Bill of 1900, and he argued that it was the fitter body to undertake the formation of the proposed Central Midwives Board.

Mr. ROBERT AMBROSE moved an amendment to the effect that the Board should consist of "seven registered medical practitioners nominated by the General Medical Council. After two years from the passing of this Act one half of the six members of the Board selected by the General Medical Council shall retire, but shall be eligible for re election, and thereafter one half of such members of the Board shall retire annually in such manner that each of such members shall serve a *term of two years before retiring, and members so retiring shall be* eligible for re-election. In the event of the death or resignation of a member of the Board the successor elected or appointed shall hold office for the remaining period for which the deceased or resigned member was elected, and must be qualified equally with such deceased or resigned member to hold office as a member of the Board, and shall, on retiring, be eligible for re election. No member of the Board shall act as teacher, instructor or examiner of midwives, and no member of *the Board shall take any part in any inquiry respecting the conduct of* any midwife to whom he had acted as teacher or instructor."

Mr. HEYWOOD JOHNSTONE said that the committee had just decided that the General Medical Council should not have the duty and responsibility of forming the Board and now the committee was asked to say that the President of the Privy Council should have his hands tied and have a Board ready made for him on the nomination of t General Medical Council. The substantial point, however, was whe *this Central Midwives Board should be composed entirely of me* men or whether there should be laymen on it. As the Bill stoo must be a majority of registered medical practitioners on th Of the seven members four must be registered medical pr and there was nothing to say that the other three m registered medical practitioners.

Mr. T. P. O'CONNOR said he did not think that the F entirely a medical board. There might be taxation *there must be representation and therefore he ap* sentation of the county councils. At the same t medical element should predominate.

Sir WALTER FOSTER agreed that four register

This question was answered in the affirmative by a majority of 24 against 7 votes

Mr T P O Connor then said he would be prepared to move the omission of the name of the Apothecaries Society and the substitution of the General Medical Council if he thought the latter body would accept the duty of appointing one of the four registered medical practitioners

Sir John Batty Tuke They would not accept it

Mr O Connor said that in these circumstances he would move to delete the name of the Apothecaries' Society in order to substitute that of the Royal British Nurses Association This body he said was the most representative body of the women engaged in nursing in this country

Mr Heywood Johnstone asked whether the hon Member could refer to any reference to midwives in the charter of the Royal British Nurses Association

Mr O Connor said that he knew that a very considerable number of the nurses of the association were trained in midwifery and that the association had a list of members who had obtained certificates qualifying them to act as midwives

Mr Schwann said that out of 2800 nurses who were members of the association 254 had been trained as midwives

Mr O Connor insisted on urging the claims of the association the hostility to which he could not understand

Mr Heywood Johnstone assured the hon Member that he had nothing to say against the association which was in his opinion a very deserving body As a matter of fact however midwifery was really no essential part of the training of the association Moreover, the hon Member had not shown that the association had any desire to be represented in this matter

Mr O Connor The president of the association is desirous that the body should be represented

Mr Heywood Johnstone said that the question had never been brought before the association as a whole As for the Apothecaries Society its name had always appeared in these Bills and had never before been challenged

Sir John Batty Tuke pointed out that the Apothecaries Society was not a mere trading body or pharmaceutical society but one of the largest qualifying bodies in the three kingdoms

Mr John Burns added that the Society had interested itself in the midwives question as long ago as 1813

Sir Walter Foster speaking in support of the amendment said he doubted whether the total membership of the Incorporated Midwives Institute was more numerous than the nurses trained in midwifery on the list of the Royal British Nurses Association

Mr Schwann explained that the institute had 700 members

Mr O Connor thought that as the questions to be dealt with by the proposed Board would be largely questions of nursing the association should be represented in its constitution

Sir Michael Foster pointed out that the Bill dealt with midwives and not with nurses There was a tale in the medical profession as to the difference between physicians and surgeons The physicians always said that they were surgeons and something more A midwife was a nurse and something more and it was with regard to that something more that they were specially dealing in this Bill

The question was then put that the words one by the Society of Apothecaries stand part of the clause and it was answered in the affirmative by 23 votes against 5

Mr Ambrose moved to delete the Incorporated Midwives Institute in order to insert the name of the Victoria University He did so with the view of having the great manufacturing districts represented on the proposed Board

Sir Walter Foster agreed that the provinces should be represented in some way

Mr Emmott took the view that anything in the way of sectional representation of the universities would do more harm than good

The amendment was rejected by 24 votes against 3

Mr Griffith Boscawen who had not been present during the previous debate moved to give a representative to the Royal British Nurses Association

Mr O Connor intimated that he would vote for the amendment

Mr Heywood Johnstone asked the committee to reject it

On a division the amendment was rejected by 19 votes against 4

On the motion of Mr Heywood Johnstone it was agreed to give the Board power to cancel as well as to issue certificates and to add at the end of the section these words—viz Rules framed under this section shall be valid only if approved by the Privy Council and the Privy Council before approving any such rules shall submit them to the General Medical Council and shall take into consideration any representations which that Council may make with respect thereto' In moving the addition of these words the hon Member said that there must be a Government department in the background to give sanction to the rules but he hoped the words carried out the intention of the promoters of the Bill—to recognise the position of the General Medical Council and to show due deference to it by giving it a place in the Act and providing that it should be consulted

The words subject to the approval of the Privy Council after consultation with the General Medical Council were struck out of the clause

In Clause 5 dealing with fees and expenses Sir Walter Foster moved to substitute one guinea for 10s as the maximum fee to be charged to women on presenting themselves for certification He did so he said with a view of lessening the burden likely to fall upon the rates His calculation was that they would require at least £2000 a year to carry on the work connected with the qualifying of these women and he did not think one guinea too much for them to pay for their certificate

Mr Jesse Collings pointed out that the sum mentioned in the Bill originally was one guinea and 10s had been substituted at the instance of the Home Office but he was quite willing to leave the matter to the decision of the committee

Mr Heywood Johnstone said that he was prepared to accept the amendment remarking that if in experience one guinea was found to be too high a fee steps could be taken to reduce it

The amendment was agreed to

In Clause 10 dealing with notification of practice it was agreed on the motion of Mr Heywood Johnstone to insert words requiring the midwife to give notice to the local supervising authority in the month of January of every year during which she continues to practise within the area of the authority

Mr Griffith Boscawen moved to insert a new clause to provide that ' any woman certified under this Act who shall undertake the charge of a case of abnormality or disease shall be liable upon summary conviction to a fine not exceeding £10

Mr Heywood Johnstone said that no woman undertook the charge of these cases because nobody could tell beforehand when a case was going to be abnormal or normal Moreover the practice of these women would be limited and restricted within due limits by the Central Midwives Board, and if the Board could solve a question which had not yet been solved and say whether a case would be abnormal or not no doubt it would do it One of the main objects of the Bill was to have a person in attendance who would know when to send for a medical man

Sir Walter Foster said that while nobody could tell beforehand whether a case was going to be natural or abnormal it was of the greatest importance that the strongest possible incentive should be given to women in attendance to send for qualified assistance the moment anything went wrong

Mr Jesse Collings said that this matter had been very carefully considered and he hoped the committee would not accept the proposed clause

On a division it was rejected by 22 votes against 4

This completed the consideration of the Bill, and accordingly the Bill as amended was ordered for report to the House of Commons

Morse, Edward, L.R.C.P., L.R.C.S. Edin., has been re appointed Medical Officer of Health for Torrington (Devon).

Mudge, Zachary Billing, L.R.C.P., M.R.C.S., has been re appointed Medical Officer of Health by the Phillack (Cornwall) Urban District Council.

Nettle, William, M.R.C.S., L.S.A., J.P., has been re appointed Medical Officer of Health for Liskeard (Cornwall).

Palmer, A. M., M.R.C.S., L.R.C.P. Edin., has been re appointed Medical Officer of Health for the Urban District of Whittington.

Starkie, E. G. B., M.B., C.M. Edin., has been re-appointed Medical Officer of Health for Poulton-le Fylde.

Wilson, W. Cheyne, M.D., C.M. Edin., has been appointed Honorary Physician to the South Devon and East Cornwall Hospital, Plymouth.

# Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

Bedford County Hospital.—Senior House Surgeon. Salary £100 a year, with apartments, board, and washing.

Bradford Poor-law Union Hospital and Workhouse.—First Resident Assistant Medical Officer, unmarried. Salary £125, with rations, apartments, and washing.

Brecon Infirmary.—Resident House Surgeon, unmarried. Salary £120 per annum, with apartments, board, attendance, fire, and gas.

Brentford Union Infirmary and Workhouse.—Assistant Medical Superintendent, unmarried. The person appointed will be required to devote his whole time to the service of the guardians. Salary £120 per annum, with apartments, rations, washing, &c.

Bridgwater Infirmary.—House Surgeon. Salary £80 a year, with board and residence.

Brighton and Hove Lying-in Institution and Hospital for Women.—House Surgeon, unmarried. Salary £80 per annum, with apartments, board, gas, coals, and attendance.

Chelsea Hospital for Women, Fulham-road, S.W.—Pathologist.

Chesterfield and North Derbyshire Hospital and Dispensary.—Resident House Surgeon. Salary £120, with board, apartments, and laundress.

Cornwall County Asylum, Bodmin.—Junior Assistant Medical Officer. Salary £120, rising to £150, with board, apartments, &c.

Durham County Hospital.—House Surgeon, also Assistant House Surgeon. Salary of Senior £100, Junior £65, with board and lodging in each case.

Grey's Hospital, Pietermaritzburg, Natal, South Africa.—Resident Medical Superintendent. Salary, £350 first year, £400 second year, with board, lodging, and washing.

Hanley, Stoke, and Fenton Joint Hospital Board.—Lady Resident Assistant Medical Officer. Salary £60 per annum, with board, residence, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Honorarium £25.

Hoxton House Asylum, London, N.—Resident Clinical Assistant. Salary £60 a year, with board, lodging, and washing.

Liverpool Dispensaries.—Head Surgeon, unmarried. Salary £200 per annum, with board and apartments. Also two Assistant Surgeons, unmarried. Salary £100 per annum, with board and apartments.

Norfolk and Norwich Hospital.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

North-Eastern Hospital for Children, Hackney-road, N.E.—House Physician for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

Nottingham General Infirmary.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, increasing by £10 every year, with apartments, attendance, light, and fuel.

Paddington Infirmary.—Clinical Assistant; also Second Assistant to the Medical Superintendent. Both for six months. Honorarium of £36, with board, lodging, and washing.

Portsmouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £120 to £156 per annum, with board, lodging, &c.

Royal Berkshire Hospital.—House Surgeon. Also Assistant House Surgeon, both for six months. Salary £80 and £50 per annum respectively, with board, lodging, and washing.

Royal University of Ireland.—Examiners in Surgery, salary £50; Midwifery, salary £35, Pathology, salary £25; and Ophthalmology, salary £20; in each case with travelling allowances.

Southampton Incorporation, New Workhouse Infirmary, Shirley Warren.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, washing, and attendance.

Teignmouth Hospital, S. Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

Tottenham Hospital.—House Surgeon. Salary £50 per annum, with board, residence, and laundry.

Tunbridge Wells General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, gas, firing, and attendance.

Victoria Hospital Folkestone.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

Victoria Hospital for Children, Queen's-road, Chelsea, S.W. House Physician for six months. Honorarium of £25, with board and lodging.

# Births, Marriages, and Deaths.

## BIRTHS.

Bowles.—On March 13th, the wife of Alfred Bowles, M.R.C.S., L.R.C.P. Lond., of a son.

Gillbard.—On March 13th, at St. Margarets, Purley, the wife of R. Gillbard, M.R.C.S., L.R.C.P. Lond., of a son.

## MARRIAGE.

Holcroft—Richardson.—At St. Breoch Church, Wadebridge, Cornwall, on the 12th inst., W. F. Lucius Austen Holcroft, M.B., B.Ch. Edin., son of the late T. W. Holcroft of Sevenoaks, Kent, to Ruth Seymour, eldest daughter of J. B. Richardson, Esq., M.D., of Trevanion, Wadebridge, and Greenfield, Flintshire.

## DEATHS.

Eaton.—On March 15th, at St. Bartolomeo, Spezia, Italy, Colonel Robert Coleman Eaton, Royal Army Medical Corps, aged 60.

Hetley.—On March 13th, at Norbury Lodge, Upper Norwood Frederic Hetley, M.D. St. And., in his 81st year.

Johnstone.—On March 16th, at Brighton, Athol Archibald Wood Johnstone, F.R.C.S., in his 82nd year.

Preston.—On March 16th, in London, William John Preston, M.D. St. And., aged 82 years.

Theobalds.—On March 7th, at Cliffansty, Weston-super-Mare, John Robert Theobalds, Surgeon General, late I.M.S. Madras, aged 79.

*N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

---

### *TRUTH* AND AN EMINENT SURGEON'S FEE.

THE following paragraph appeared in *Truth* of March 13th and requires a few words of comment:—

> The desire to get all you can and stick to it is not, I imagine, confined to any one profession or trade. A gentleman who did not—luckily for him—happen to know any London doctor, recently wrote, on the advice of a pharmaceutical chemist, to an eminent London surgeon asking for an appointment for his wife. He stated at the same time that the lady was suffering from insomnia, kidney derangement, and swelling of the feet. The appointment was made and the lady attended, but after a short consultation the surgeon said, as was to be expected, that the case was not one for him, but for a physician. For this opinion he charged three guineas. The husband then wrote explaining the circumstances under which he asked for the appointment, and that he was ignorant at the time that he was addressing a surgeon, not a physician. He pointed out that it must have been obvious from his first letter that the case was not one for a surgeon, he denied the right of the doctor to take a fee under such circumstances, and he demanded the return of the three guineas. His demand was certainly made in a peremptory rather than a conciliatory tone, but the answer was still more peremptory:—
>
> — Cavendish square, W.,
> February 13, 1902.
>
> SIR,—My solicitor's name and address are — ——, Esq., ——— street, E.C.
>
> I am yours faithfully,
> — ———

We do not understand why it was lucky that the husband "did not happen to know any London doctor," as the trouble seems to have arisen precisely from his ignorance in that direction. Nor can we admit that it must have been obvious to the eminent London surgeon from the husband's first letter "that the case was not one for a surgeon," for nothing can ever be certainly deduced from a layman's letters. Who diagnosed kidney derangement? Presumably the pharmaceutical chemist. And obviously insomnia and swelled feet can each and both have a *surgical cause*. The eminent London surgeon was perfectly right to see the patient. If, as the story goes in *Truth*, after a short "consultation" (examination is probably meant) the eminent surgeon was able to say confidently that the case was not one which he could treat we do not think that he should have asked for or retained a fee. But if the valuable time of the eminent surgeon was much taken up in finding out that the case was a medical case—not a point that it would be as easy for an eminent surgeon as *for a pharmaceutical chemist to decide*—and certainly if there was any consultation, he ought to be paid for his trouble. If the husband had consulted his family medical man in the first instance he would not have made a mistake that has led to his wasting three guineas, but because he has not a family medical man and is so unfortunate as not "to know any London doctor," why should he waste an eminent surgeon's time with impunity? By the way, there are only four surgeons living in Cavendish square, but perhaps "*Cavendish Square*" is a sort of *generic address for an* eminent surgeon.

### WANTED—A HOME.

*To the Editors of* THE LANCET.

SIRS,—Could any of your readers inform me if there are any homes, either seaside or country, where a weak-minded boy could be taken care of and at the same time receive a little education? In this case the parents are not well off but could afford to pay a small amount a year.

I am, Sirs, yours faithfully,
E. CHAMBERS MUSPRATT.

27, Darlington-street, Wolverhampton.

### THE "TRIUMPH" STOKER.

AGAIN and again have we urged that in the case of the furnaces of factories or of electric light generating stations or of mammoth hotels *there can be no* excuse for the production of filthy black *smoke*. It is only deliberate negligence in regard to stoking which leads to the formation of smoke in these instances. Our attention in this connexion has been drawn to a new mechanical stoker known as the "Triumph" stoker which gives most satisfactory results, for not only is the production of smoke prevented, but, as is inevitable, an economy of fuel and a clear gain of heating efficiency result. The "stoker" secures the sprinkling of the coal over the fire at intervals in such a way that two successive charges never fall in the same place. In other words, the fire is never choked by adding an excess of fuel and the furnace is thus cooled down as little as possible, while air gains access to every particle of fuel. The apparatus works quite automatically and with little attention and we could detect no smoke issuing from the chimney on the occasion of more than one surprise visit which we paid to a factory where the "Triumph" stokers were at work. There can be little doubt that if such an appliance could be universally adopted the evil of fog would be greatly minimised. And there is no reason why it should not be so, for the apparatus is quite simple and easily managed, while it leads to a great saving of fuel which would amply repay the manufacturer or others for the initial outlay *incurred*. *The "Triumph" stoker is manufactured by* **Messrs.** Ransomes and Rapier, engineers, of London and Ipswich.

### "PUBLIC HEALTH IN ITALY."

WE have received a copy of a little paper published in Rome entitled "Public Health in Italy: Official Notes." Probably some of our readers have seen the paper already, which has for its laudable object "the patriotic intention to remove all the Calumnies which foreign newspapers propagate respecting the sanitary state of Italy." The programme of the paper is better than its English, judging by the specimen which has been sent to us. The sanitary office of the Commune of Rome, for example, states that:—

> Last January we enjoyed a very good weather and it is well known that no infective disease passed through Rome. On such a purpose we may add that Rome is not a fruitful ground for infective diseases, so that *in* Rome *it is* very *difficult to such* disease to unfold themselves. As to what regards the *malaria* there is no need to spend too many words to state that during these months there is no *malaria* in Rome.

This particular number includes an article on Rome as a health resort by Mr. J. J. Eyre.

### THE NASAL DOUCHE AS A PREVENTIVE.

*To the Editors of* THE LANCET.

SIRS,—Now that we are in the midst of an epidemic of small-pox I should like to call attention to the necessity for the proper sanitation of the nasal passages and would plead for a doctrine which I have preached to my patients for some years—viz., the thorough and regular washing out of the nose and naso-pharynx. We all know the condition of the inside of the nose with its happy family of microbes, &c. I am sure that if the organ was properly cleansed daily with a slightly astringent douche such as a weak solution of sea salt we should hear much less of diseased condition and it would be much less likely to afford a channel for infectious germs. The saline douche washes away the accumulation of dirt and acting also as a slight astringent keeps the mucous membrane healthy and renders it less likely to absorb poisonous germs. Children should be taught to use the nasal douche when they are taught to use the tooth brush.

I am, Sirs, yours faithfully,
Devonshire street, W., March 11th, 1902. W. R. H. STEWART.

### THE DIAGNOSIS OF SYPHILIS.

*To the Editors of* THE LANCET.

SIRS,—May I beg for an answer to the following questions through the medium of THE LANCET:—(1) The possibility and reliability of the differential diagnosis of the hard and soft chancre by bacteriological methods; (2) the best method of demonstrating the bacillus of syphilis (Lustgarten) in films from hard chancre; (3) the bacillus of soft sore, how may it be demonstrated and distinguished from other organisms; and (4) literature on the above.

I am, Sirs, yours faithfully,
March 17th, 1902. BACTERIOLOGIST.

*** Our correspondent's questions are by no means easy to answer. Lustgarten's bacillus is only the most likely organism which has yet been described to prove the cause of syphilis. It is very difficult to stain even in a section of a hard sore and we doubt whether any trustworthy result could be got by staining films from the living sore. Ducrey's bacillus of soft chancre has been cultivated, though with difficulty. The evidence that it really is the cause of soft sore is fairly good. A tolerably complete account of the subject with literature will be found in No. 6 of the "Referate" of the *Centralblatt für Bakteriologie* for this year. (This journal is now published in two parts, "Referate" and "Originale.") The article to which we refer is a "Zusammenfassendes Referat"—i.e., a complete account of the knowledge of the subject up to date.—ED. L.

### CLIMATE AND CHRONIC PULMONARY TROUBLE.

*To the Editors of* THE LANCET.

SIRS,—Can any of your readers kindly tell me why with some persons where there is a chronic tendency to torpidity (from heart dilatation) of the lungs, *tending to slight congestion of the lungs, a dry, cold* air suits them and not a cold damp air?

I am, Sirs, yours faithfully,
Bournemouth, March 18th, 1902. HENRY A. HAMMOND.

### RECRUDESCENCE OF THE POCKS IN VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—Cases of revaccination with recrudescence of the pocks appear to be fairly common but receive no comment in the literature. I have seen three cases lately in which from four to six weeks after the revaccination, the scabs having fallen off, a fresh pock has developed on one of the scars and after going through a normal or somewhat hurried cycle has scabbed over. What is the explanation? It is usually supposed, I believe, that fresh pocks cannot be produced after the areola

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to* THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

BAIGENT, W., M.D. Durh., has been re-appointed Medical Officer of Health for Northallerton.

BREGLING, D. H., B.A. Syd. Univ., M.B., C.M. Edin., has been appointed Medical Officer to the Post-office at Huddersfield.

BRODRICK, CHARLES CUMBERLAND, L.R.C.P., L.R.C.S., L.M. Edin., has been appointed Medical Officer and Public Vaccinator for the Whitchurch District of the Tavistock (Devon) Union for three years.

CHEESEWRIGHT, J. F., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health to the Greasborough Urban District Council.

CRUISE, RICHARD, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Bristol Eye Hospital.

EVANS, J. JAMESON, M.B. Edin., F.R.C.S. Eng., has been appointed Ophthalmic Surgeon to the Birmingham Workhouse and the Marston green Cottage Homes.

FINDLAY, G. B., M.B. Aberd., has been re-appointed Medical Officer of Health for Brailes.

FLETCHER, J. L., M.B., C.M. Edin., has been re-appointed Medical Officer of Health to the South Darley Urban District Council.

GAYLOR, E., L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer for Alfreton Rural District.

GOODING, MATTHEW RICHARD, L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for the Barnstaple Port Sanitary Authority.

HIGHET, H. CAMPBELL, M.D. Glasg., D.P.H., has been appointed Medical Officer of Health for Bangkok, vice Dr. P. A. Nightingale, retired.

HOLMES, CHAS. J., M.B., B.S. Durh., has been appointed Junior Resident House Surgeon to the Provincial Hospital, Port Elizabeth, Cape Colony.

JUDSON, J. E., M.R.C.S. Eng., L.R.C.P. Lond., late Senior Resident Medical Officer of the Manchester Workhouse, Crumpsall, has been appointed House Surgeon to the District Infirmary, Ashton-under-Lyne.

KERSWILL, JOHN BEDFORD, M.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health by the St. Germans (Cornwall) District Council.

MEACHEN, G. NORMAN, M.B., B.S. Lond., M.R.C.P. Edin., has been appointed Honorary Dermatologist to the Tottenham Hospital, N.

MORSE, EDWARD, L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for Torrington (Devon).

MUDGE, ZACHARY BILLING, L.R.C.P., M.R.C.S., has been re-appointed Medical Officer of Health by the Phillack (Cornwall) Urban District Council.

NETTLE, WILLIAM, M.R.C.S., L.S.A., J.P., has been re-appointed Medical Officer of Health for Liskeard (Cornwall).

PALMER, A. M., M.R.C.S., L.R.C.P. Edin., has been re-appointed Medical Officer of Health for the Urban District of Whittington.

STARKIE, E. G. B., M.B., C.M. Edin., has been re-appointed Medical Officer of Health for Poulton-le-Fylde.

WILSON, W. CHEYNE, M.D., C.M. Edin., has been appointed Honorary Physician to the South Devon and East Cornwall Hospital, Plymouth.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement (see Index).*

BEDFORD COUNTY HOSPITAL.—Senior House Surgeon. Salary £100 a year, with apartments, board, and washing.

BRADFORD POOR-LAW UNION HOSPITAL AND WORKHOUSE.—First Resident Assistant Medical Officer, unmarried. Salary £125, with rations, apartments, and washing.

BRECON INFIRMARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with apartments, board, attendance, fire, and gas.

BRENTFORD UNION INFIRMARY AND WORKHOUSE.—Assistant Medical Superintendent, unmarried. The person appointed will be required to devote his whole time to the service of the guardians. Salary £120 per annum, with apartments, rations, washing, &c.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 a year, with board and residence.

BRIGHTON AND HOVE LYING-IN INSTITUTION AND HOSPITAL FOR WOMEN.—House Surgeon, unmarried. Salary £80 per annum, with apartments, board, gas, coals, and attendance.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Pathologist.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY.—Resident House Surgeon. Salary £120, with board, apartments, and laundress.

CORNWALL COUNTY ASYLUM, Bodmin.—Junior Assistant Medical Officer. Salary £120, rising to £150, with board, apartments, &c.

DURHAM COUNTY HOSPITAL.—House Surgeon, also Assistant House Surgeon. Salary of Senior £100, Junior £65, with board and lodging in each case.

GREY'S HOSPITAL, Pietermaritzburg, Natal, South Africa.—Resident Medical Superintendent. Salary, £350 first year, £400 second year, with board, lodging, and washing.

HANLEY, STOKE, AND FENTON JOINT HOSPITAL BOARD.—Lady Resident Assistant Medical Officer. Salary £60 per annum, with board, residence, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians for six months. Honorarium £25.

HOXTON HOUSE ASYLUM, London, N.—Resident Clinical Assistant. Salary £60 a year, with board, lodging, and washing.

LIVERPOOL DISPENSARIES.—Head Surgeon, unmarried. Salary £200 per annum, with board and apartments. Also two Assistant Surgeons, unmarried. Salary £100 per annum, with board and apartments.

NORFOLK AND NORWICH HOSPITAL.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, N.E.—House Physician for six months. Salary at rate of £80 per annum, with board, residence, and laundry.

NOTTINGHAM GENERAL INFIRMARY.—Assistant Resident Surgeon, unmarried. Salary £160 per annum, increasing by £10 every year, with apartments, attendance, light, and fuel.

PADDINGTON INFIRMARY.—Clinical Assistant; also Second Assistant to the Medical Superintendent. Both for six months. Honorarium of £36, with board, lodging, and washing.

PORTSMOUTH BOROUGH ASYLUM.—Assistant Medical Officer, unmarried. Salary £120 to £156 per annum, with board, lodging, &c.

ROYAL BERKSHIRE HOSPITAL.—House Surgeon. Also Assistant House Surgeon, both for six months. Salary £80 and £50 per annum respectively, with board, lodging, and washing.

ROYAL UNIVERSITY OF IRELAND.—Examiners in Surgery, salary £50; Midwifery, salary £35; Pathology, salary £25; and Ophthalmology, salary £20; in each case with travelling allowances.

SOUTHAMPTON INCORPORATION, NEW WORKHOUSE INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, washing, and attendance.

TEIGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £70 a year, with board, lodging, and washing.

TOTTENHAM HOSPITAL.—House Surgeon. Salary £50 per annum, with board, residence, and laundry.

TUNBRIDGE WELLS GENERAL HOSPITAL.—House Surgeon, unmarried. Salary £100 per annum, with board, apartments, gas, firing, and attendance.

VICTORIA HOSPITAL, Folkestone.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

VICTORIA HOSPITAL FOR CHILDREN, Queen's road, Chelsea, S.W.—House Physician for six months. Honorarium of £25, with board and lodging.

## Births, Marriages, and Deaths.

### BIRTHS.

BOWLES.—On March 13th, the wife of Alfred Bowles, M.R.C.S., L.R.C.P. Lond., of a son.

GILLBARD.—On March 13th, at St. Margarets, Purley, the wife of R. Gillbard, M.R.C.S., L.R.C.P. Lond., of a son.

### MARRIAGE.

HOLCROFT—RICHARDSON.—At St. Breoch Church, Wadebridge, Cornwall, on the 12th inst., W. F. Lucius Austen Holcroft, M.B., B.Ch. Edin., son of the late T. W. Holcroft of Sevenoaks, Kent, to Ruth Seymour, eldest daughter of J. B. Richardson, Esq., M.D., of Trevanion, Wadebridge, and Greenfield, Flintshire.

### DEATHS.

EATON.—On March 15th, at St. Bartolomeo, Spezia, Italy, Colonel Robert Coleman Eaton, Royal Army Medical Corps, aged 60.

HETLEY.—On March 13th, at Norbury Lodge, Upper Norwood, Frederic Hetley, M.D. St. And., in his 81st year.

JOHNSTONE.—On March 16th, at Brighton, Athol Archibald Wood Johnstone, F.R.C.S., in his 82nd year.

PRESTON.—On March 16th, in London, William John Preston, M.D. St. And., aged 82 years.

THEOBALDS.—On March 7th, at Cliffansty, Weston-super-Mare, John Robert Theobalds, Surgeon-General, late I.M.S. Madras, aged 79.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## *TRUTH* AND AN EMINENT SURGEON'S FEE.

THE following paragraph appeared in *Truth* of March 13th and requires a few words of comment:—

> The desire to get all you can and stick to it, is not, I imagine, confined to any one profession or trade. A gentleman who did not—luckily for him—happen to know any London doctor, recently wrote on the advice of a pharmaceutical chemist to an eminent London surgeon asking for an appointment for his wife. He stated at the same time that the lady was suffering from insomnia, kidney derangement, and swelling of the feet. The appointment was made and the lady attended, but after a short consultation the surgeon said, as was to be expected, that the case was not one for him, but for a physician. For this opinion he charged three guineas. The husband then wrote explaining the circumstances under which he asked for the appointment, and that he was ignorant at the time that he was addressing a surgeon, not a physician. He pointed out that it must have been obvious from his first letter that the case was not one for a surgeon; he denied the right of the doctor to take a fee under such circumstances, and he demanded the return of the three guineas. His demand was certainly made in a peremptory rather than a conciliatory tone, but the answer was still more peremptory:—
>
> — Cavendish square, W.,
> February 13, 1902.
>
> SIR,—My solicitor's name and address are — ——, Esq., ——— street, E.C.
>
> I am yours faithfully,
> — ———

We do not understand why it was lucky that the husband "did not happen to know any London doctor," as the trouble seems to have arisen precisely from his ignorance in that direction. Nor can we admit that it must have been obvious to the eminent London surgeon from the husband's first letter "that the case was not one for a surgeon," for nothing can ever be certainly deduced from a layman's letters. Who diagnosed kidney derangement? Presumably the pharmaceutical chemist. And obviously insomnia and swelled feet can each and both have a surgical cause. The eminent London surgeon was perfectly right to see the patient. If, as the story goes in *Truth*, after a short "consultation" (examination is probably meant) the eminent surgeon was able to say confidently that the case was not one which he could treat we do not think that he should have asked for, or retained, a fee. But if the valuable time of the eminent surgeon was much taken up in finding out that the case was a medical case—not a point that it would be as easy for an eminent surgeon as for a pharmaceutical chemist to decide—and certainly if there was any consultation, he ought to be paid for his trouble. If the husband had consulted his family medical man in the first instance he would not have made a mistake that has led to his wasting three guineas, but because he has not a family medical man and is so unfortunate as not "to know any London doctor," why should he waste an eminent surgeon's time with impunity? By the way, there are only four surgeons living in Cavendish square, but perhaps "Cavendish Square" is a sort of generic address for an eminent surgeon.

## WANTED—A HOME.

*To the Editors of* THE LANCET.

SIRS,—Could any of your readers inform me if there are any homes either seaside or country, where a weak-minded boy could be taken care of and at the same time receive a little education? In this case the parents are not well off but could afford to pay a small amount a year.

I am, Sirs, yours faithfully,
E. CHAMBERS MUSPRATT.

27, Darlington-street, Wolverhampton.

## THE "TRIUMPH" STOKER.

AGAIN and again have we urged that in the case of the furnaces of factories or of electric light generating stations or of mammoth hotels there can be no excuse for the production of filthy black smoke. It is only deliberate negligence in regard to stoking which leads to the formation of smoke in these instances. Our attention in this connexion has been drawn to a new mechanical stoker known as the "Triumph" stoker which gives most satisfactory results, for not only is the production of smoke prevented, but, as is inevitable, an economy of fuel and a clear gain of heating efficiency result. The "stoker" secures the sprinkling of the coal over the fire at intervals in such a way that two successive charges never fall in the same place. In other words, the fire is never choked by adding an excess of fuel and the furnace is thus cooled down as little as possible while air gains access to every particle of fuel. The apparatus works quite automatically and with little attention and we could detect no smoke issuing from the chimney on the occasion of more than one surprise visit which we paid to a factory where the "Triumph" stokers were at work. There can be little doubt that if such an appliance could be universally adopted the evil of fog would be greatly minimised. And there is no reason why it should not be so, for the apparatus is quite simple and easily managed, while it leads to a great saving of fuel which would amply repay the manufacturer or others for the initial outlay incurred. The "Triumph" stoker is manufactured by Messrs. Ransomes and Rapier, engineers, of London and Ipswich.

## "*PUBLIC HEALTH IN ITALY.*"

WE have received a copy of a little paper published in Rome entitled "Public Health in Italy: Official Notes." Probably some of our readers have seen the paper already, which has for its laudable object "the patriotic intention to remove all the Calumnies which foreign newspapers propagate respecting the sanitary state of Italy." The programme of the paper is better than its English, judging by the specimen which has been sent to us. The sanitary office of the Commune of Rome, for example, states that:—

> "Last January we enjoyed a very good weather and it is well known that no infective disease passed through Rome. On such a purpose we may add that Rome is not a fruitful ground for infective diseases so that in Rome it is very difficult to such diseases to unfold themselves. As to what regards the *malaria* there is no need to spend too many words to state that during these months there is no *malaria* in Rome."

This particular number includes an article on Rome as a health resort by Mr. J. J. Eyre.

## THE NASAL DOUCHE AS A PREVENTIVE.

*To the Editors of* THE LANCET.

SIRS,—Now that we are in the midst of an epidemic of small-pox I should like to call attention to the necessity for the proper sanitation of the nasal passages and would plead for a doctrine which I have preached to my patients for some years—viz., the thorough and regular washing out of the nose and naso-pharynx. We all know the condition of the inside of the nose with its happy family of microbes, &c. I am sure that if the organ was properly cleansed daily with a slightly astringent douche, such as a weak solution of sea salt, we should hear much less of diseased condition and it would be much less likely to afford a channel for infectious germs. The saline douche washes away the accumulation of dirt and acting also as a slight astringent keeps the mucous membrane healthy and renders it less likely to absorb poisonous germs. Children should be taught to use the nasal douche when they are taught to use the tooth brush.

I am, Sirs, yours faithfully,
Devonshire-street, W., March 11th, 1902. W. R. H. STEWART.

## THE DIAGNOSIS OF SYPHILIS.

*To the Editors of* THE LANCET.

SIRS,—May I beg for an answer to the following questions through the medium of THE LANCET:—(1) The possibility and reliability of the differential diagnosis of the hard and soft chancre by bacteriological methods; (2) the best method of demonstrating the bacillus of syphilis (Lustgarten) in films from hard chancre; (3) the bacillus of soft sore, how may it be demonstrated and distinguished from other organisms; and (4) literature on the above.

*I am, Sirs, yours faithfully,*
March 17th, 1902. BACTERIOLOGIST.

*** Our correspondent's questions are by no means easy to answer. Lustgarten's bacillus is only the most likely organism which has yet been described to prove the cause of syphilis. It is very difficult to stain even in a section of a hard sore, and we doubt whether any trustworthy result could be got by staining films from the living sore. Ducrey's bacillus of soft chancre has been cultivated, though with difficulty. The evidence that it really is the cause of soft sore is fairly good. A tolerably complete account of the subject with literature will be found in No. 6 of the "Referate" of the *Centralblatt für Bakteriologie* for this year. (This journal is now published in two parts, "Referate" and "Originale.") The article to which we refer is a "Zusammenfassendes Referat"—i.e., a complete account of the knowledge of the subject up to date.—ED. L.

## CLIMATE AND CHRONIC PULMONARY TROUBLE.

*To the Editors of* THE LANCET.

SIRS,—Can any of your readers kindly tell me why with some persons where there is a chronic tendency to torpidity (from heart dilatation) of the lungs, tending to slight congestion of the lungs, a dry, cold air suits them and not a cold, damp air?

I am, Sirs, yours faithfully,
Bournemouth, March 18th, 1902. HENRY A. HAMMOND.

## RECRUDESCENCE OF THE POCKS IN VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—Cases of revaccination with recrudescence of the pocks appear to be fairly common but receive no comment in the literature. I have seen three cases lately in which from four to six weeks after the revaccination, the scabs having fallen off, a fresh pock has developed on one of the scars and after going through a normal or somewhat hurried cycle has scabbed over. What is the explanation? It is usually supposed, I believe, that fresh pocks cannot be produced after the areola are formed in existing pocks—i.e., until after some years, when the immunity disappears. In these cases, however, it appears as if some re-infection must occur or as if some organism had lain dormant for many weeks and then become active. I should be glad if any of your readers could offer a better explanation.

I am, Sirs, yours faithfully,
S. HENNING BELFRAGE.

## PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

*To the Editors of* THE LANCET.

SIRS,—I beg to inclose a further list of subscribers to the memorial to Surgeon-General Nash, for favour of publication if you have space.

I am, Sirs, yours faithfully,
B. M. SKINNER, Major R.A.M.C.
(Secretary to the Fund).

18, Victoria-street, S.W., March 18th, 1902.

## CONTRACT PRACTICE.

*To the Editors of* THE LANCET.

SIRS,—Will you kindly insert the following in the next issue of THE LANCET:—

The amalgamated clubs at Retford, Notts, are, we understand, about to advertise for a medical officer. It would be advisable for any gentleman, before entering into a contract with the above clubs, to correspond with any of the undersigned medical men already in practice at Retford.—We are Sirs, yours faithfully,

TREVOR J. PRITCHARD, M.B. Edin.
R. J. TRISTAN, L R.C.P. Edin.
G. THOMSON, M.B., C M. Edin.
W. E. CUTHBERTSON, L.R.C.P. Edin.
C. WESTBROOK, M.D. St. And.
J. M THORNE, M.R.C.S. Eng.
Retford, March 17th, 1902. P. E. BEARBLOCK, M.R.C.S. Eng.

## THE R. B. ANDERSON FUND.

THE honorary secretary of this fund has forwarded to us the following communication, dated March 18th —

> Lord Stamford and his committee beg to state that this fund is now closed, and to return their sincere thanks to the Editors and Proprietors of THE LANCET and the medical press generally for the valuable space which they have from time to time placed at their disposal. They now take this last opportunity of thanking those who have so generously responded to the appeal. In all, the sum of £257 5*s.* 6*d.* has been sent out to Sir C. C Knollys, K.C.M.G. Colonial Secretary of Trinidad, who has kindly consented, in conjunction with the Warden of Tobago, to dispose of this amount as far as possible for the permanent benefit of the late Mr. Anderson's widow and twin sons, and in due course to furnish an account of his expenditure for publication. Net amount published: £241 17*s.* Further amounts have been received from Dr. P. Frank, £3 3*s.*; from Dr. B. G. M. Baskett, Mr. H. Cropley, Mr. F. G. Evans, Dr. R. Emmett, Dr. E. Elliott, Dr. Q. Priestly, Mr. G. B. Robathan, Mr. H. L. Smith, Mr. H Stear, Dr. J. Thomarson, and Dr. C. H. Taylor, £1 1*s.* each; from Dr. H. Shelmerdine, Dr. J. O. Brookhouse, and an anonymous donor, 10*s.* 6*d.* each; from Dr. T. C. Beatty and Mr. G. C. Franklin, 10*s.* each; and from Dr. L. Lewis, 5*s.*, bringing up the total to £259 7*s.* 6*d.*, from which £2 2*s.* have been paid to the honorary secretary in respect of some of the out-of-pocket expenses, leaving a sum of £257 5*s.* 6*d.* which has been remitted, together with an additional sum of £1 from Mr. A. E. Prest Hughes (Straits Settlements) which was received after the auditing and certification of the accounts.

## SYPHILIS WITHOUT PRIMARY SORE (?)

*To the Editors of* THE LANCET.

SIRS,—I have a case of secondary syphilis under my care. All the usual symptoms are present and it is yielding to the usual remedies. Some years ago the same patient was treated for similar symptoms by the late Mr. Berkeley Hill who had no doubt as to the nature of the case. But the peculiarity is that there is no evidence of chancre or any primary sore. My patient cannot remember any sore on any part of his body and it is difficult to see how such should be overlooked. I write to ask if any such cases have occurred in your experience or that of your readers.

I am, Sirs, yours faithfully,
March 19th, 1902. J. W. A.

## MANUFACTURE OF OZONE.

*To the Editors of* THE LANCET.

SIRS,—In reply to your correspondent "Inquirer" in THE LANCET of March 15th, p. 769, who desired to know where he could obtain an apparatus for the production of ozone, may I inform him that the Electric Ozone Syndicate of 5, New Union-street, Moorgate, supply such apparatus? I am, Sirs, yours faithfully,

R. V. WOOD HUNTER,
Technical Manager and Chemist to the Electric
March 18th, 1902. Ozone Syndicate, Limited.

◆

*A. A.*—1. For convenience generally at 60° F. 2. Taking the specific gravity of water at its maximum density—namely, 4° C.—as unity, at 60° F., or 15·5° C., the specific gravity would be 0·9991. 3. Usually to water at 60° F., or 15·5° C. 4. The fluid must be measured and weighed under the same conditions of temperature at which unity is fixed but with known mixtures; tables of corrections at different temperatures can be consulted. 5. The question is not clear, for the examples given purporting to state the specific gravity of a mixture of alcohol and water are considerably higher than the specific gravity of pure water. The specific gravity of an original mixture cannot necessarily be deduced from the specific gravity of the same mixture to which a known volume of water has been added. Shrinkage should be made up by adding more water.

*Mr. P. Dalgado.*—There is no one volume, so far as we know, dealing with the subjects of renal disease and diabetes other than text-books of medicine. Our correspondent will perhaps find what he requires in monographs in vols. iii. and iv. of Allbutt's System of Medicine, also in Dr. R. W. Saundby's "Lectures on Bright's Disease" and "Lectures on Diabetes"; also in Mr. Henry Morris's "Surgical Diseases of the Kidney and Ureter."

*Bella Vista* must consult her usual medical attendant.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

# Medical Diary for the ensuing Week.

### *TRUTH* AND AN EMINENT SURGEON'S FEE

THE following paragraph appeared in *Truth* of March 13th and requires a few words of comment —

> The desire to get all you can, and stick to it, is not, I imagine, confined to any one profession or trade A gentleman who did not —luckily for him—happen to know any London doctor, recently wrote, on the advice of a pharmaceutical chemist, to an eminent London surgeon asking for an appointment for his wife He stated at the same time that the lady was suffering from insomnia, kidney derangement and swelling of the feet The appointment was made, and the lady attended, but after a short consultation the surgeon said, as was to be expected, that the case was not one for him, but for a physician For this opinion he charged three guineas The husband then wrote explaining the circumstances under which he asked for the appointment, and that he was ignorant at the time that he was addressing a surgeon, not a physician. He pointed out that it must have been obvious from his first letter that the case was not one for a surgeon, he denied the right of the doctor to take a fee under such circumstances, and he demanded the return of the three guineas His demand was certainly made in a peremptory rather than a conciliatory tone, but the answer was still more peremptory —
>
> — Cavendish square, W ,
> February 13 1902.
>
> SIR —My solicitor's name and address are —. —— Esq , ——— street, E C
>
> I am yours faithfully,
>
> — ———

We do not understand why it was lucky that the husband 'did not happen to know any London doctor,' as the trouble seems to have arisen precisely from his ignorance in that direction Nor can we admit that it must have been obvious to the eminent London surgeon from the husband s first letter "that the case was not one for a surgeon," for nothing can ever be certainly deduced from a layman s letters Who diagnosed kidney derangement? Presumably the pharmaceutical chemist And obviously insomnia and swelled feet can each and both have a surgical cause The eminent London surgeon was perfectly right to see the patient If, as the story goes in *Truth*, after a short "consultation' (examination is probably meant) the eminent surgeon was able to say confidently that the case was not one which he could treat we do not think that he should have asked for, or retained, a fee But if the valuable time of the eminent surgeon was much taken up in finding out that the case was a medical case—not a point that it would be as easy for an eminent surgeon as for a pharmaceutical chemist to decide—and certainly if there was any consultation, he ought to be paid for his trouble If the husband had consulted his family medical man in the first instance he would not have made a mistake that has led to his wasting three guineas, but because he has not a family medical man and *is so unfortunate as not "to know any London doctor*, why should he waste an eminent surgeon s time with impunity? By the way, there are only four surgeons living in Cavendish square, but perhaps "Cavendish Square' is a sort of generic address for an eminent surgeon

### WANTED—A HOME

*To the Editors of* THE LANCET

SIRS,—Could any of your readers inform me if there are any homes, either seaside or country, where a weak minded boy could be taken care of and at the same time receive a little education? In this case the parents are not well off but could afford to pay a small amount a year

I am, Sirs, yours faithfully,

E CHAMBERS MUSPRATT

27, Darlington street, Wolverhampton

### THE "TRIUMPH' STOKER.

AGAIN and again have we urged that in the case of the furnaces of factories or of electric light generating stations or of mammoth hotels there can be no excuse for the production of filthy black smoke It is only deliberate negligence in regard to stoking which leads to the formation of smoke in these instances Our attention in this connexion has been drawn to a new mechanical stoker known as the "Triumph" stoker which gives most satisfactory results for not only is the production of smoke prevented, but, as is inevitable, an economy of fuel and a clear gain of heating efficiency result The "stoker" secures the sprinkling of the coal over the fire at intervals in such a way that two successive charges never fall in the same place In other words the fire is never choked by adding an excess of fuel and the furnace is thus cooled down as little as possible while air gains access to every particle of fuel The apparatus works quite automatically and with little attention and we could detect no smoke issuing from the chimney on the occasion of more than one surprise visit which we paid to a factory where the ' Triumph' stokers were at work There can be little doubt that if such an appliance could be universally adopted the evil of fog would be greatly minimised And there is no reason why it should not be so for the apparatus is quite simple and easily managed, while it leads to a great saving of fuel which would amply repay the manufacturer or others for the initial outlay incurred The "Triumph' stoker is manufactured by Messrs. Ransomes and Rapier, engineers, of London and Ipswich

### ' PUBLIC HEALTH IN ITALY

WE have received a copy of a little paper published in Rome entitled "Public Health in Italy Official Notes Probably some of our readers have seen the paper already, which has for its laudable object " the patriotic intention to remove all the Calumnies which foreign newspapers propagate respecting the sanitary state of Italy.' The programme of the paper is better than its English, judging by the specimen which has been sent to us The sanitary office of the Commune of Rome for example, states that —

> ' Last January we enjoyed a very good weather and it is well known that no infective disease passed through Rome On such a purpose we may add that Rome is not a fruitful ground for infective diseases so that in Rome it is very difficult to such disease to unfold themselves As to what regards the *malaria* there is no need to spend too many words to state that during these months there is no *malaria* in Rome '

This particular number includes an article on Rome as a health resort by Mr J. J. Eyre

### THE NASAL DOUCHE AS A PREVENTIVE

*To the Editors of* THE LANCET.

SIRS,—Now that we are in the midst of an epidemic of small pox I should like to call attention to the necessity for the proper sanitation of the nasal passages and would plead for a doctrine which I have preached to my patients for some years—viz , the thorough and regular washing out of the nose and naso pharynx We all know the condition of the inside of the nose with its happy family of microbes &c I am sure that if the organ was properly cleansed daily with a slightly astringent douche such as a weak solution of sea salt, we should hear much less of diseased condition and it would be much less likely to afford a channel for infectious germs The saline douche washes away the accumulation of dirt and acting also as a slight astringent keeps the mucous membrane healthy and renders it less likely to absorb poisonous germs Children should be taught to use the nasal douche when they are taught to use the tooth brush

I am, Sirs, yours faithfully,

Devonshire street, W March 11th 1902 W. R H STEWART.

### THE DIAGNOSIS OF SYPHILIS

*To the Editors of* THE LANCET.

SIRS —May I beg for an answer to the following questions through the medium of THE LANCET —(1) The possibility and reliability of the differential diagnosis of the hard and soft chancre by bacteriological methods, (2) the best method of demonstrating the bacillus of syphilis (Lustgarten) in films from hard chancre, (3) the bacillus of soft sore, how may it be demonstrated and distinguished from other organisms, and (4) literature on the above

I am, Sirs, yours faithfully,

March 17th, 1902 BACTERIOLOGIST.

*** Our correspondent s questions are by no means easy to answer Lustgarten's bacillus is only the most likely organism which has yet been described to prove the cause of syphilis It is very difficult to stain even in a section of a hard sore, and we doubt whether any trustworthy result could be got by staining films from the living sore. Ducrey s bacillus of soft chancre has been cultivated, though with difficulty. The evidence that it really is the cause of soft sore is fairly good A tolerably complete account of the subject with literature will be found in No 6 of the "Referate' of the *Centralblatt für Bakteriologie* for this year (This journal is now published in two parts, "Referate and "Originale') The article to which we refer is a "Zusammenfassendes Referat'—i e, a complete account of the knowledge of the subject up to date —ED L

### CLIMATE AND CHRONIC PULMONARY TROUBLE

*To the Editors of* THE LANCET

SIRS,—Can any of your readers kindly tell me why with some persons where there is a chronic tendency to torpidity (from heart dilatation) of the lungs, tending to slight congestion of the lungs a dry, cold air suits them and not a cold, damp air?

I am, Sirs, yours faithfully,

Bournemouth, March 18th, 1902 HENRY A HAMMOND.

### RECRUDESCENCE OF THE POCKS IN VACCINATION.

*To the Editors of* THE LANCET

SIRS,—Cases of revaccination with recrudescence of the pocks appear to be fairly common but receive no comment in the literature I have seen three cases lately in which from four to six weeks after the revaccination, the scabs having fallen off, a fresh pock has developed on one of the scars and after going through a normal or somewhat hurried cycle has scabbed over. What is the explanation? It is usually supposed, I believe, that fresh pocks cannot be produced after the areola are formed in existing pocks—i.e., until after some years, when the immunity disappears. In these cases, however, it appears as if some re-infection must occur or as if some organism had lain dormant for many weeks and then become active. I should be glad if any of your readers could offer a better explanation.

I am, Sirs, yours faithfully,
S. Henning Belfrage.

## PROPOSED MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH, A.M.S.

*To the Editors of* The Lancet.

Sirs,—I beg to inclose a further list of subscribers to the memorial to Surgeon-General Nash, for favour of publication if you have space.

I am, Sirs, yours faithfully,
B. M. Skinner, Major R.A.M.C.
(Secretary to the Fund).

18, Victoria-street, S.W., March 18th, 1902.

## CONTRACT PRACTICE.

*To the Editors of* The Lancet.

Sirs,—Will you kindly insert the following in the next issue of The Lancet:—

The amalgamated clubs at Retford, Notts, are, we understand, about to advertise for a medical officer. It would be advisable for any gentleman, before entering into a contract with the above clubs, to correspond with any of the undersigned medical men already in practice at Retford.—We are Sirs, yours faithfully,

Trevor J. Pritchard, M.B. Edin.
R. J. Tristan, L R.C.P. Edin.
G. Thomson, M.B., C.M. Edin.
W. E. Cuthbertson, L.R.C.P. Edin.
C. Westbrook, M.D. St. And.
J. M. Thornf, M.R.C.S. Eng.
Retford, March 17th, 1902. P. E. Bfarblock, M.R.C.S. Eng.

## THE R. B. ANDERSON FUND.

The honorary secretary of this fund has forwarded to us the following communication, dated March 18th:—

> Lord Stamford and his committee beg to state that this fund is now closed, and to return their sincere thanks to the Editors and Proprietors of The Lancet and the medical press generally for the valuable space which they have from time to time placed at their disposal. They now take this last opportunity of thanking those who have so generously responded to the appeal. In all, the sum of £257 5*s.* 6*d.* has been sent out to Sir C. C. Knollys, K.C.M.G. Colonial Secretary of Trinidad, who has kindly consented, in conjunction with the Warden of Tobago, to dispose of this amount as far as possible for the permanent benefit of the late Mr. Anderson's widow and twin sons, and in due course to furnish an account of his expenditure for publication. Net amount published: £241 17*s.* Further amounts have been received from Dr. P. Frank, £3 3*s.*; from Dr. B. G. M. Baskett, Mr. H. Cropley, Mr. F. G. Evans, Dr. R. Emmett, Dr. E. Elliott, Dr. Q. Priestly, Mr. G. B. Robathan, Mr. H. L. Smith, Mr. H Stear, Dr. J. Thomarson, and Dr. C. H. Taylor, £1 1*s.* each; from Dr. H. Shelmerdine, Dr. J. O. Brookhouse, and an anonymous donor, 10*s.* 6*d.* each; from Dr. T. C. Beatty and Mr. G. C. Franklin, 10*s.* each; and from Dr. L. Lewis, 5*s.*, bringing up the total to £259 7*s.* 6*d.*, from which £2 2*s.* have been paid to the honorary secretary in respect of some of the out-of-pocket expenses, leaving a sum of £257 5*s.* 6*d.* which has been remitted, together with an additional sum of £1 from Mr. A. E. Prest Hughes (Straits Settlements) which was received after the auditing and certification of the accounts.

## SYPHILIS WITHOUT PRIMARY SORE (?)

*To the Editors of* The Lancet.

Sirs,—I have a case of secondary syphilis under my care. All the usual symptoms are present and it is yielding to the usual remedies. Some years ago the same patient was treated for similar symptoms by the late Mr. Berkeley Hill who had no doubt as to the nature of the case. But the peculiarity is that there is no evidence of chancre or any primary sore. My patient cannot remember any sore on any part of his body and it is difficult to see how such should be overlooked. I write to ask if any such cases have occurred in your experience or that of your readers.

I am, Sirs, yours faithfully,
March 19th, 1902. J. W. A.

## MANUFACTURE OF OZONE.

*To the Editors of* The Lancet.

Sirs,—In reply to your correspondent "Inquirer" in The Lancet of March 15th, p. 789, who desired to know where he could obtain an apparatus for the production of ozone, may I inform him that the Electric Ozone Syndicate of 5, New Union-street, Moorgate, supply such apparatus? I am, Sirs, yours faithfully,

R. V. Wood Hunter,
Technical Manager and Chemist to the Electric
March 18th, 1902. Ozone Syndicate, Limited.

◆

*A. A.*—1. For convenience generally at 60° F. 2. Taking the specific gravity of water at its maximum density—namely, 4° C.—as unity, at 60° F., or 15·5° C., the specific gravity would be 0·9991. 3. Usually to water at 60° F., or 15·5° C. 4. The fluid must be measured and weighed under the same conditions of temperature at which unity is fixed but with known mixtures; tables of corrections at different temperatures can be consulted. 5. The question is not clear, for the examples given purporting to state the specific gravity of a mixture of alcohol and water are considerably higher than the specific gravity of pure water. The specific gravity of an original mixture cannot necessarily be deduced from the specific gravity of the same mixture to which a known volume of water has been added. Shrinkage should be made up by adding more water.

*Mr. P. Dalgado.*—There is no one volume, so far as we know, dealing with the subjects of renal disease and diabetes other than text-books of medicine. Our correspondent will perhaps find what he requires in monographs in vols. iii. and iv. of Allbutt's System of Medicine, also in Dr. R. W. Saundby's "Lectures on Bright's Disease" and "Lectures on Diabetes"; also in Mr. Henry Morris's "Surgical Diseases of the Kidney and Ureter."

*Bella Vista* must consult her usual medical attendant.

Communications not noticed in our present issue will receive attention in our next.

# Medical Diary for the ensuing Week.

## OPERATIONS.

### METROPOLITAN HOSPITALS.

**MONDAY** (24th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.) West London (2.30 P.M.), London Throat (2 P.M.).

**TUESDAY** (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Royal Ear (3 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**WEDNESDAY** (26th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.).

**THURSDAY** (27th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (2 P.M.), St. Mark's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.).

**FRIDAY** (28th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.). West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square, (9.30 A.M.), City Orthopædic (2.30 P.M.).

**SATURDAY** (29th).—Royal Free (9 A.M. and 2 P.M.), London (2 P.M.) Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9 15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.), Throat, Golden-square (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

## SOCIETIES.

**MONDAY** (24th).—MEDICAL SOCIETY OF LONDON (11, Chandos street, Cavendish-square, W.).—8.30 P.M. Discussion on the Treatment of Puerperal Eclampsia (opened by Dr. G. E. Herman). Council Meeting Night.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover square, W.).—7 P.M. Council. 8 P.M. Communications:—Mr. C. W. Glassington: A Composite Odontome.—Mr. E. B. Dowsett: Alveolar Abscess perforating the Palate.—Mr. A. Underwood: Two Cases in Practice.—Mr. D. Lloyd Williams: Fatal Case of Alveolar Abscess.

**TUESDAY** (25th).—CHELSEA CLINICAL SOCIETY (Jenner Institute of Preventive Medicine, Chelsea gardens, Grosvenor-road, S.W.).—8 30 P.M. Annual Clinical Debate:—Cancer, its Nature, Origin, and General Principles of Treatment. The following, among others, will take part in the discussion—Prof. Hewlett, Mr. D'Arcy Power, Dr. H. R. Gaylord (New York) (Communication on Cancer in Swine, with lantern slides), Prof. Adami (Montreal) (Communication), and Dr. J. F. Payne (who will deliver the closing address).

ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8 30 P.M. Mr A. W. Mayo Robson The Surgical Treatment of Obstruction in the Common Bile duct by Concretions, with especial reference to the Operation of Choledochotomy as modified by the author (illustrated by 60 cases).

## LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

**MONDAY** (24th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. T. Colcott Fox: Clinique. (Skin.)

**TUESDAY** (25th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. C. T. Williams: Clinique. (Medical.)

***WEDNESDAY** (26th).—MEDICAL GRADUATES' COLLEGE AND POLY*CLINIC (22, Chenies street, W.C.).—4 P.M. Mr. J. Clarke: Clinique. (Surgical.)

**THURSDAY** (27th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr. J. Hutchinson, jun: Clinique. (Surgical.)

**FRIDAY** (28th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. StClair Thomson: Clinique. (Throat.)

## EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*Lectures, original articles, and reports should be written on one side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*We cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1901, which was completed with the issue of Dec. 28th, and the Title-page to the Volume, were given in THE LANCET of Jan 4th.

### *VOLUMES AND CASES.*

VOLUMES for the second half of the year 1901 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? *Subscriptions paid to London or to local* newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of *subscriptions, post free, either from* THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... ... | 0 16 3 | Six Months ... ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

# The Lumleian Lectures

ON

# THE COMPREHENSIVE STUDY OF THORACIC PHTHISIS.

*Delivered before the Royal College of Physicians of London on March 13th, 18th, and 20th, 1902,*

By F T ROBERTS, M D, F R C P Lond,

HOLME PROFESSOR OF CLINICAL MEDICINE AT UNIVERSITY COLLEGE, SENIOR PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, CONSULTING PHYSICIAN TO BROMPTON CONSUMPTION HOSPITAL ETC

## LECTURE I

*Delivered on March 13th*

Mr President and Gentlemen,—The group of cases which are so sadly familiar under the terms "phthisis" and "consumption" have, for obvious reasons, always exerted a powerful attraction, not only for members of the medical faculty, but also for the laity While they have contributed enormously to the human death rate, and caused widespread and profound misery and distress amongst all classes of the community, high and low, rich and poor, they have been further surrounded with a halo of mystery in the past, which has attached to them a peculiar sentimental interest and dread Moreover, these cases have compelled the attention of many earnest investigators and seekers after truth, and one supreme object has been to endeavour to discover a "cure' for this strange and terrible disease Need it be wondered at that, from the very nature of the conditions, quacks of various kinds have found "consumption" a "happy hunting ground," and a source of considerable financial prosperity, each, of course, claiming to have discovered the long-looked-for "cure" This gold-mine shows no signs of being "worked out," even in this enlightened age

The scientific discoveries and practical advances in our knowledge in relation to tuberculosis and phthisis, which have been such a remarkable outcome of modern researches, have cleared away all mystery and sentiment, and things have now assumed a very commonplace aspect Nevertheless the subject has excited an ever-increasing, deeper, and more widespread interest, mainly on account of the ardent hopes which have been roused with regard to the effective treatment, prevention, and ultimate eradication of a malady which has hitherto been looked upon as a "hopeless scourge" In fact, "consumption" may now be described as being "in the air," I mean figuratively, as well as infectively In this country an "Association for the Prevention of Consumption and Other Forms of Tuberculosis" was established in 1898 and this was followed by the British Congress on Tuberculosis which took place in London last July This Congress was highly successful from a scientific, oratorical, social, and let us hope a practical point of view It was characterised by at least one dramatic incident, and by the enunciation of some strong statements of opinion which have since excited considerable discussion and opposition At its closing general meeting the members of the congress carried certain resolutions, well meaning enough but whether likely to lead to practical results commensurate with the occasion remains to be seen I note that, although the point was referred to by some speakers, the congress did not dare to incorporate in these resolutions any advice to ladies not to sweep up the filth of the streets and pavements, with the disease germs therein contained by means of their trailing dresses

Those who have followed the course of events during the last few months must have realised the fact that the Congress has not been an unmixed benefit Of course, on the one hand, it has been the starting-point of markedly increased activity and development in relation to the agencies and methods for the prevention and cure of consumption which have taken such a firm hold upon the imagination of the community at large, and which have appealed so strongly to the practical sympathy and benevolence of many who have the means to help Moreover, it has led to the discussion in the medical press of important questions which there is every reason to hope may lead to useful results So far good But, on the other hand, much of the correspondence, more particularly in the lay press cannot fail to have led to serious mischief Indeed, in a certain influential daily newspaper the heading "Congress on Tuberculosis" has been ever since until quite recently the introduction to very disagreeable and aggravating reading, the far-reaching injurious effects of which upon a credulous and easily gulled public it is impossible to estimate We can afford as a profession to ignore the insults which have been heaped upon us in this correspondence, and surely we ought to treat with the utmost ridicule and contempt the insolent and impudent suggestions made with regard to "testing" and "scientifically investigating" any supposed "cure for consumption" that is not perfectly open and above board Still, for the sake of humanity we cannot be altogether silent, and personally I feel bound to take this opportunity of protesting strongly against any member of our profession countenancing in the slightest degree such a proposal Of course, we cannot prevent any fussy and officious busybodies or so-called philanthropists from thrusting themselves to the front, giving dogmatic opinions about subjects of which they are absolutely ignorant and supporting any pretentious treatment they choose, but our plain duty is to leave them severely alone

Personally I did not take any active part in the Congress on Tuberculosis, as on these occasions I prefer to be a humble disciple This gathering is, however, somewhat directly responsible for the subject which I have selected for these lectures, for reasons with which I will not trouble you, but which may possibly be revealed in the course of my remarks I trust that my long connexion with the Brompton Hospital for Consumption gives me a certain claim to be heard with respect to thoracic phthisis, at any rate in its more practical and clinical aspects I do not for a moment pretend to bring before you anything original, novel, or startling, and can only hope to present facts or to offer suggestions in such a way as to be of some service to the profession in dealing with this still terrible scourge I fear that I did not realise at starting what an extensive and difficult task I had set myself within the limited time at my disposal, and in the actual delivery of these lectures, at any rate, I must omit the discussion of many points in detail, while, with regard to others, I can confidently rely on the general information and knowledge of my audience You may be glad to know that I have no intention of boring you with dull statistics or with lengthy descriptions of cases Nor do I propose to quote many authorities, though from no want of respect for their labours or teaching

Before proceeding to the actual discussion of my subject I feel bound to offer a mild protest against the modern tendency to regard all questions relating to phthisis too exclusively from the scientific side, and to accept no doctrine or opinion as reliable or authoritative unless it emanates from the pathological or bacteriological laboratory While expressing my profound admiration for, and appreciation of, the valuable work which has been, and is still being, done in these laboratories in relation to tuberculosis, I submit that this does not cover the whole field, and that phthisis, as it comes before us in actual life, must be dealt with and studied on a much broader basis and from other standpoints My friend and colleague, Dr G Vivian Poore, in a recent interesting address on "Milk and its Relation to Health and Disease," holds that the question of the relationship between bovine and human tuberculosis cannot be settled by laboratory experiments only, and that we must not set aside its practical, clinical, and epidemiological aspects This statement of opinion, with which I cordially agree, applies with equal force to many other questions bearing upon tuberculosis and phthisis

The title which I have given to these lectures indicates the intention and scope of my subject I have employed the expression "thoracic phthisis' advisedly, to emphasise what are, in my opinion, two most important practical facts—namely, first, that in the cases of chest disease usually and conveniently grouped as "consumption," the morbid changes are by no means limited to the lungs, but in the large majority of instances other thoracic structures are more or less affected as well, and the mischief may even originate in certain of these structures; and secondly, that, even assuming the disease to be essentially a manifestation of tuberculosis, other lesions and pathological changes may be associated with the tuberculous mischief from the first or from an early period; while they are certain to develop or supervene in various combinations and degrees during the progress of cases which are at all prolonged, and especially in those of a markedly chronic type. Ultimately the conditions not uncommonly become extremely complicated. In other words, "thoracic phthisis" and "pulmonary tuberculosis or consumption" are by no means synonymous terms, a fact which is but too often entirely ignored or forgotten. Recognising these fundamental facts, it is obviously most desirable that thoracic phthisis should be studied, both scientifically and practically, on a comprehensive basis, on certain lines which it will be my business to endeavour to elucidate in these lectures. Having thus adequately mastered the subject in the abstract, and gained a fairly intelligent and definite knowledge of facts, and not of mere theories, assumptions, or doctrines, and having acquired adequate skill in clinical investigation, the trained practitioner must then regard it as his imperative and unfailing duty to deal with every individual case which comes under his care from this comprehensive standpoint, to study it systematically and thoughtfully, so as to be in a position to give rational and reliable advice, to do the best that is possible for this unfortunate class of patients, and to take suitable and adequate measures of a prophylactic or preventive nature, so far as circumstances permit.

The several points which it is my purpose to discuss in these lectures in relation to the comprehensive study of thoracic phthisis come conveniently and naturally under the following familiar general headings: I.—Pathology and Etiology; II.—Morbid Anatomy or Pathological Changes; and III.—Clinical History and Investigation. An intelligent and practical knowledge and appreciation of the facts which we learn from these aspects is absolutely essential as a rational basis for IV.—Treatment and Prevention. A friend said to me when he heard of my choice of a subject for these lectures, "Now be sure to tell us all about the treatment of consumption" Well, Sir, I am sorry to disappoint him, for I do not propose to deal with this branch at all, except, it may be, to make an incidental allusion to particular points, and for the following reasons. In the first place, it hardly comes within the scope of my subject as defined by the title which I have adopted. Secondly, the other divisions include much more than I can possibly discuss satisfactorily within the time at my disposal, and it would be quite absurd and hopeless to attempt to deal with the treatment and prevention of consumption at the fag end in any way commensurate with its immense importance. Thirdly, there is so much written on the subject at the present time, so many "cures" advocated, and such an amount of discussion on various matters of detail, that I feel sure that you must be all pretty well bewildered; if I ventured to say anything I should probably only add to the general confusion and chaos. Personally I really feel so dazed with what I have read and with the statements made that I have almost come to the conclusion that neither I nor anyone else knows much about the matter. And having no "cure." or even "cut-and-dried method of treatment" for thoracic phthisis, I have no special reason for inflicting my views and opinions upon you.

## I.—PATHOLOGY AND ETIOLOGY.

I presume that few, if any, would question for a moment at the present day the essential relationship between tubercle and thoracic phthisis, or would deny that this morbid product takes a most prominent and active part in the pathological manifestations of the disease. Moreover, its direct connexion with the *tubercle bacillus* and its consequent infective nature are almost universally recognised and acknowledged, though there are some who are still unconvinced I read the other day a review of a work dealing with pulmonary consumption in which it is maintained that the disease is not contagious, and that in the large majority of cases it is primarily a neurosis, the pulmonary disintegration being secondary. As a protest against such absurd and mischievous teaching I take the earliest opportunity of emphasising the importance of always bearing in mind infection as a common and dangerous factor in the causation of thoracic phthisis. And in this connexion it would ill become me if I did not pause, to pay my tribute of profound respect and admiration to that greatest of bacteriologists—Koch, whose scientific investigations, culminating in the discovery of the tubercle bacillus, and the complete demonstration of its relation to tuberculous lesions, has been well described as "a classical masterpiece of bacteriological research."

But while fully appreciating and endorsing the infective aspect of the pathology and etiology of thoracic phthisis, on the other hand, it cannot be too strongly enforced at the present day that this does not cover the entire ground. Public attention is now so concentrated upon the "contagiousness of consumption," and the idea of infection is so absorbing and so overshadows all else, that other practical factors in originating or developing the complaint are either entirely lost sight of, or at any rate are not insisted upon or brought into such prominence as they ought to be. Moreover, statements are made bearing upon its causation which in my opinion are not in accordance with fact, and to some of these I shall have to refer in the course of my remarks.

I do not propose to trouble you with any discussion of the different points bearing upon the bacteriology of thoracic phthisis, which at present seems to be in a somewhat unsettled state, including the question of so-called "pseudotuberculosis." I will merely draw attention to the fact that there are other well-known pathogenic organisms besides the tubercle bacillus which are as a rule concerned, more or less, in what I may call the phthisical process, regarding it comprehensively, especially the pneumococcus and the pyogenic microbes with which you are all familiar, and which I need not enumerate. In short, "mixed or combined," as well as "secondary" infections are undoubtedly common, and are especially prominent in many of the more acute cases. Experimental investigations have shown that pyogenic organisms have in all probability an important effect in hastening necrosis and softening of tuberculous consolidation, while later their influence becomes obvious enough in connexion with phthisical lesions. The organisms which occasionally are found in the walls of cavities, including amongst them certain moulds and fungi, may be of some importance as destructive agents, but nothing definite can be stated on this point, so far as I am aware.

I now desire to offer a few remarks on the question of the contagiousness or infectivity of thoracic phthisis, as it comes before us in actual practice. I presume that there are but few, if any, members of the medical profession who regard consumption as contagious in the ordinary and popular acceptance of the term, that is, as being conveyed from one individual to another in the same way as measles or smallpox. But undoubtedly this is the idea which is very prevalent amongst the laity, and I have met with not a few instances in which it has proved a serious inconvenience, difficulty, or hardship. The fact cannot be ignored that the modern prominence given to the contagiousness of consumption has created quite a scare amongst large numbers of people which materially interferes with commercial, professional, social, and practical life. I believe that certain places which actually owe their prosperity to the fact that they claimed special advantages as health-resorts for consumptive patients, now repudiate the attachment altogether and do their utmost to boycott such patients, and to prevent them from coming there, as it is found that they keep other people away whose patronage is now far more lucrative. Some places absolutely refuse all consumptives; and things have gone so far in the United States that the Government has recently issued an order excluding all tuberculous immigrants from that country, which has elicited an emphatic protest from the New York Academy of Medicine. It is our business as a profession at once to endeavour to allay this excessive and unreasoning alarm, and to make the laity understand that, with very simple precautions, there need be little or no fear of infection in this way. The actual experience in health-resorts for consumptives in the higher altitudes does not favour the idea of infection when due care is taken. Nor do I think that we are called upon to warn people, as has been lately suggested, against going themselves or taking their children to the Zoological Gardens lest they should "catch consumption" from our kinsfolk—the monkeys.

But unfortunately there is another side to the case. I suppose we are all pretty well agreed that the main source of infection is the dried sputum, which contains the tubercle bacilli in countless millions, and these are deposited and carried about attached to fine particles of dust, being thus always liable to be inhaled from the atmosphere. There is another view—that infection is chiefly conveyed by the free, finely divided particles of sputum ejected in the act of coughing, which are suspended in the atmosphere and then inhaled. This mode of conveyance ought certainly not to be ignored. It is usually dogmatically stated that the breath of a consumptive patient is not infectious, as tubercle

HOLME PROFESSOR OF CLINICAL MEDICINE AT UNIVERSITY COLLEGE; SENIOR PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, CONSULTING PHYSICIAN TO BROMPTON CONSUMPTION HOSPITAL, ETC.

## LECTURE I.

*Delivered on March 13th*

Mr. President and Gentlemen,—The group of cases which are so sadly familiar under the terms "phthisis" and "consumption" have, for obvious reasons, always exerted a powerful attraction, not only for members of the medical faculty, but also for the laity. While they have contributed enormously to the human death-rate, and caused widespread and profound misery and distress amongst all classes of the community, high and low, rich and poor, they have been further surrounded with a halo of mystery in the past, which has attached to them a peculiar sentimental interest and dread. Moreover, these cases have compelled the attention of many earnest investigators and seekers after truth; and one supreme object has been to endeavour to discover a "cure" for this strange and terrible disease. Need it be wondered at that, from the very nature of the conditions, quacks of various kinds have found "consumption" a "happy hunting ground," and a source of considerable financial prosperity, each, of course, claiming to have discovered the long-looked-for "cure." This gold-mine shows no signs of being "worked out," even in this enlightened age.

The scientific discoveries and practical advances in our knowledge in relation to tuberculosis and phthisis, which have been such a remarkable outcome of modern researches, have cleared away all mystery and sentiment, and things have now assumed a very commonplace aspect. Nevertheless the subject has excited an ever-increasing, deeper, and more widespread interest, mainly on account of the ardent hopes which have been roused with regard to the effective treatment, prevention, and ultimate eradication of a malady which has hitherto been looked upon as a "hopeless scourge." In fact, "consumption" may now be described as being "in the air," I mean figuratively, as well as infectively. In this country an "Association for the Prevention of Consumption and Other Forms of Tuberculosis" was established in 1898 and this was followed by the British Congress on Tuberculosis which took place in London last July. This Congress was highly successful from a scientific, oratorical, social, and let us hope a practical point of view. It was characterised by at least one dramatic incident, and by the enunciation of some strong statements of opinion which have since excited considerable discussion and opposition. At its closing general meeting the members of the congress carried certain resolutions, well-meaning enough, but whether likely to lead to practical results commensurate with the occasion remains to be seen. I note that, although the point was referred to by some speakers, the congress did not dare to incorporate in these resolutions any advice to ladies not to sweep up the filth of the streets and pavements, with the disease-germs therein contained, by means of their trailing dresses.

Those who have followed the course of events during the last few months must have realised the fact that the Congress has not been an unmixed benefit. Of course, on the one hand, it has been the starting-point of markedly increased activity and development in relation to the agencies and methods for the prevention and cure of consumption which have taken such a firm hold upon the imagination of the community at large, and which have appealed so strongly to the practical sympathy and benevolence of many who have the means to help. Moreover, it has led to the discussion in the medical press of important questions which there is every reason to hope may lead to useful results. So far good. But, on the other hand, much of the correspondence, more particularly in the lay press, cannot fail to have led to serious mischief. Indeed, in a certain influential daily newspaper the heading "Congress on Tuberculosis" has been ever since until quite recently the introduction to very disagreeable and aggravating reading, the far-reaching injurious effects of which upon a credulous and easily-gulled public it is impossible to estimate. We can afford as a profession to ignore the insults which have been heaped upon us in this correspondence, and surely we ought to treat with the utmost ridicule and contempt the insolent and impudent suggestions made with regard to "testing" and "scientifically investigating" any supposed "cure for consumption" that is not perfectly open and above-board. Still, for the sake of humanity we cannot be altogether silent, and personally I feel bound to take this opportunity of protesting strongly against any member of our profession countenancing in the slightest degree such a proposal. Of course, we cannot prevent any fussy and officious busybodies or so-called philanthropists from thrusting themselves to the front, giving dogmatic opinions about subjects of which they are absolutely ignorant and supporting any pretentious treatment they choose; but our plain duty is to leave them severely alone.

Personally I did not take any active part in the Congress on Tuberculosis, as on these occasions I prefer to be a humble disciple. This gathering is, however, somewhat directly responsible for the subject which I have selected for these lectures, for reasons with which I will not trouble you, but which may possibly be revealed in the course of my remarks. I trust that my long connexion with the Brompton Hospital for Consumption gives me a certain claim to be heard with respect to thoracic phthisis, at any rate in its more practical and clinical aspects. I do not for a moment pretend to bring before you anything original, novel, or startling, and can only hope to present facts or to offer suggestions in such a way as to be of some service to the profession in dealing with this still terrible scourge. I fear that I did not realise at starting what an extensive and difficult task I had set myself within the limited time at my disposal, and in the actual delivery of these lectures, at any rate, I must omit the discussion of many points in detail; while, with regard to others, I can confidently rely on the general information and knowledge of my audience. You may be glad to know that I have no intention of boring you with dull statistics or with lengthy descriptions of cases. Nor do I propose to quote many authorities, though from no want of respect for their labours or teaching

Before proceeding to the actual discussion of my subject I feel bound to offer a mild protest against the modern tendency to regard all questions relating to phthisis too exclusively from the scientific side, and to accept no doctrine or opinion as reliable or authoritative unless it emanates from the pathological or bacteriological laboratory. While expressing my profound admiration for, and appreciation of, the valuable work which has been, and is still being, done in these laboratories in relation to tuberculosis, I submit that this does not cover the whole field, and that phthisis, as it comes before us in actual life, must be dealt with and studied on a much broader basis and from other standpoints. My friend and colleague, Dr. G Vivian Poore, in a recent interesting address on "Milk and its Relation to Health and Disease," holds that the question of the relationship between bovine and human tuberculosis cannot be settled by laboratory experiments only, and that we must not set aside its practical, clinical, and epidemiological aspects. This statement of opinion, with which I cordially agree, applies with equal force to many other questions bearing upon tuberculosis and phthisis

The title which I have given to these lectures indicates the intention and scope of my subject. I have employed the expression "thoracic phthisis" advisedly, to emphasise what are, in my opinion, two most important practical facts—namely, first, that in the cases of chest disease usually and conveniently grouped as "consumption," the morbid changes are by no means limited to the lungs, but in the large majority of instances other thoracic structures are more or less affected as well, and the mischief may even originate in certain of these structures; and secondly, that, even assuming the disease to be essentially a manifestation of tuberculosis, other lesions and pathological changes may be associated with the tuberculous mischief from the first

3 *Those in which tubercle bacilli are inhaled in a room*, office, workshop, or other place where due care has not been taken with regard to phthisical expectoration, or where proper disinfection after occupation by phthisical patients has not been carried out. How far thoracic phthisis may arise independently and directly in this way must be a matter of speculation, but certainly this mode of infection ought never to be made light of or disregarded. As an illustrative case I may mention that of a young man who was brought to me suffering from pronounced consumption which was attributed to the fact that he had worked at a desk where a clerk had previously worked who died from rapid phthisis. He came from a sound stock, had enjoyed excellent health, had led an active and vigorous life, was quite satisfactory as regards habits in every way, and there appeared no reason whatever why he should have become phthisical, except from this direct infection.

I have seen it stated that no arrangements are made in post-offices in this country as regards expectoration, while in addition their want of ventilation and other sanitary defects are but too evident. Consequently phthisis from direct infection is highly probable under such circumstances, and the mortality from this disease amongst the employés in these offices is stated to be decidedly high, to say nothing of dangers to the public.

### *B.—Infection from Within—Auto-Infection.*

That thoracic phthisis may be secondary to a tuberculous lesion in some other part of the body is well known and acknowledged in a general kind of way, but my belief is that the actual facts bearing upon auto-infection are by no means adequately recognised or appreciated. It has appeared to me that in some instances of this kind tubercle bacilli are not the only infective agents, but that pyogenic organisms have also to be taken into account. *This auto-infection may* apparently be quite independent or accidental; but in other cases it is started or brought out by some more or less definite cause, it may be very slight or quite trivial, or by operative procedures for the cure or removal of tuberculous lesions or their effects. And here it may be noted that the question of infection by food may, from this aspect, have a practical though indirect bearing upon the development of thoracic phthisis, inasmuch as the primary mischief may [illegible] n originated. Direct local infection through [illegible] stem has also to be borne in mind. In other [illegible] mischief may not have been primarily tuber[illegible] has been the result of injury or of inflammatory [illegible] low or suppurative type, the tuberculous infection [illegible] ndary.

[illegible] to the sources of auto-infection in the causation of [illegible] phthisis, I should very much have liked if I could [illegible] cussed at some length this aspect of my subject. [illegible] e present occasion, however, I can only enumerate the [illegible] mary lesions which I *have found to be practically* worthy of consideration, excluding the possible manifestation of active thoracic tuberculosis as a development under favourable conditions of latent congenital *infection* by tubercle bacilli, through the medium of the blood-current or in other ways, which in my opinion is highly probable within certain limits. These lesions are:—1 Affections of the absorbent glands in the vicinity of the chest, especially in the neck and axilla, the thoracic disease being due either to direct extension or to infection through the lymphatic vessels 2 Diseases of bones or joints, often of traumatic origin, and the suppurative or ulcerative lesions associated therewith. In this connexion I must particularly mention disease of the lower jaw, sometimes following injury from tooth extraction, of which I have met with some very definite examples. More commonly, however, the mischief is quite remote. 3 Affections of the throat, tonsils, naso-pharynx, or nasal cavities. I feel that I am trenching here on difficult ground, but there can be *no doubt as to the presence, not uncommonly*, of tubercle bacilli, or organisms resembling them, in these parts, as well as of non-tuberculous lesions of a possibly infective character, and experience has taught me to be on my guard against them in relation to thoracic phthisis, especially if there are chronic so-called scrofulous conditions. 4. Ischio-rectal abscess and subsequent fistula in ano. I regard these conditions as most important foci of auto-infection in relation to thoracic phthisis, of which I have met with many conspicuous examples, and anything of this nature ought to be always regarded as a source of serious danger in individual cases, which calls for efficient operative treatment as a *preventive measure*. 5. Other more definite tuberculous lesions affecting structures outside the chest, especially abdominal. Thus thoracic phthisis may follow such disease of the intestines, not forgetting the appendix vermiformis; the peritoneum (no doubt in some cases by direct extension through the diaphragm); the lacteal glands; the urinary system; the prostate gland; the sexual or generative apparatus in males or females; and the suprarenal capsules. Tuberculous affections of the skin may also be noticed here. As regards the intestines, I have been much surprised at the statement of Koch and others that *primary implication of these structures is rare*, as I have met with several very definite cases of this nature. 6. Latent foci of infection within the chest. Cases originating from such foci may be fairly recognised as a definite group due to auto-infection. It is a well-known fact that the quiescent remains of a former limited phthisical lesion are often found post mortem, of which there is no history whatever, or it has only been suspected, or if detected has been arrested and cured. Again, there may be the remnants of a pleurisy, or the mediastinal glands may be infected with tubercle bacilli or be the seat of definite tubercle or its products, of which we know nothing. Under these circumstances some cause, it may be a very slight and inadequate one, such as a chill, starts an active process, which may end in very rapid and grave tuberculosis, involving different structures within the chest.

### *C.—Personal Inherent Predisposition.*

It requires some courage nowadays even to hint that consumption is not altogether a matter of organisms and infection, and especially that there is any inherent personal tendency to the complaint. I congratulate Sir Dyce Duckworth on the admirable address which he delivered before the Liverpool Medical Institution on Oct. 24th, 1901, on "The Personal Factor in Tuberculosis," in which he stuck up manfully for the "host," and on the discussion which it elicited. I desire to support him in a mild and humble sort of way, and to bring before you prominently what experience has taught me with regard to personal *intrinsic conditions as predisposing to thoracic phthisis*. It is not necessary to refer particularly to race, sex, or age, except to observe that thoracic phthisis may be met with in very young subjects, as well as in old people.

1. *Heredity.*—It must be well known to you all that for a considerable time the idea has been gaining ground that the old notion of the hereditary character of consumption was entirely wrong, and not a few in our profession support this idea in the most aggressive and dogmatic fashion, looking almost with contempt upon anyone who is in any degree of the contrary opinion. The late Sir Richard Thorne, shortly before his lamented death, in an address on "The Prevention of Consumption," which contained much valuable advice, if it could only be carried out, used very strong language on this point, urging his hearers not to "go on believing the lie that consumption ran in families." Koch, at the Congress on Tuberculosis, made this statement: "It has been demonstrated by thorough investigation that, though hereditary tuberculosis was not absolutely non-existent, it was, nevertheless, extremely rare, and we were at liberty in considering our practical measures to leave that form of origination entirely out of account." When an overwhelming authority speaks thus, *ex cathedrâ*, what can one say? And yet I venture to affirm that it is a most dangerous doctrine. Of course, the influence of heredity has been greatly exaggerated in times past, and a large proportion of cases attributed to this cause were merely the result of infection associated with family life. But I have seen too much of hereditary tuberculosis and phthisis under a variety of circumstances where the patients were not exposed to any possible infection beyond what falls to the common lot to allow myself to shut my eyes to the fact that it is an etiological factor which ought never to be disregarded or made light of, from different points of view. I do not mean to say that the occurrence of a single case of consumption in a family, or still more in some collateral relative, implies heredity, but the probability of the transmission of the complaint in this way is increased in proportion as it seems to run in a family, particularly through succeeding generations, or if the predisposition exists on both sides.

Now I do not wish to make too much of this question of heredity, and it is decidedly necessary to warn people, on the other hand, against supposing that, because they come bacilli cannot be detected in the expired air, but personally I do not feel altogether satisfied on this point; at any rate, it is well to err on the safe side. One most disagreeable, not to say disgusting, possible mode of infection by tubercle bacilli has been suggested—namely, the imperfect washing of glasses in public-houses and restaurants into which consumptive patients have coughed, the expectoration being thus left in the glass or clinging to its edge.

It would be an impertinence on my part if I were even to mention the measures which must be familiar to all, and which are now carried out on such an extensive scale, for dealing with the expectoration of phthisical patients on preventive lines. But there comes the serious question—How far are they successful? In institutions and amongst communities where they can be effectually practised of course incalculable good is being done in this direction, and it would to-day be a disgrace to any fairly educated and respectable individual, or to a household where phthisis existed, if the instructions at command for dealing with the sputum were not thoroughly attended to. But unfortunately there are many obvious reasons which must render our utmost efforts for exterminating the tubercle bacillus only partially successful At present things are certainly anything but satisfactory. In our open streets, even in those inhabited by the "upper classes," as well as by "fashionable physicians" and "specialists on consumption," to say nothing of the main highways of commerce or of side streets or "slums," one may still see at any time on the pavement or the roadway enough phthisical sputum to infect a whole district or city, having regard to the enormous number of organisms which it contains, and their distribution *is abundantly promoted and aided by the ordinary* methods of sweeping pavements and streets, the hoisting of all kinds of filth and débris into dust-carts, and various other performances, not forgetting the "trailing dresses," by which the air we breathe is polluted and poisoned. What the state of things is in the large majority of houses or rooms where phthisis exists it is not pleasant to contemplate; while often no effort whatever is made subsequently to get rid of the infectious elements, to disinfect rooms, or to deal with contaminated fomites. Then bacilli are also thrown at you in countless abundance by the shaking of mats and carpets in your very face. And, notwithstanding polite requests, stringent regulations, by-laws, and penalties, the filthy habit of spitting is *still* quite common in places of general resort and in public vehicles. Things are little or no better in the smaller towns and villages or hamlets

There are two other points which more immediately concern the medical profession and the nursing department to which I must allude in this connexion. I have a strong impression that much phthisical sputum, even in hospitals, is often only very imperfectly disinfected, and is then disposed of in a casual manner down a water-closet or in some other way. What happens afterwards depends upon circumstances, but it is not unreasonable to suppose that *infection may thus* be carried far and wide. Another point of importance is that other discharges besides expectoration, coming from tuberculous lesions, as well as tainted urine or fæces, contain tubercle bacilli, it may be in large numbers, and if neglected, as they often are, may become a prolific source of infection.

Now, the picture which I have drawn of the existing state of things, though there is, I hope, the promise of progressive improvement as education advances, is rather alarming, and seems *to indicate considerable* risk of infection in various directions to all members of the community who are obliged to go out into the world, and to take part in its active life or work, while thousands upon thousands, from the unavoidable conditions of their normal existence, are necessarily and inevitably exposed more or less constantly to the possible injurious effects of tubercle bacilli in a pronounced and concentrated form. And the danger is increased from the fact that these organisms possess such a remarkable tenacity of life and resisting powers, so that they can live for a long time after their discharge in all kinds of places, and may thus set up disease at a remote period The only natural agent that seems to *destroy them speedily* and efficiently is the powerful light of the sun, but, unfortunately, that does not help us much in this country as a rule. Undoubtedly, too, tubercle bacilli retain their virulence for an indefinite period in connexion with stained handkerchiefs, bed-clothes, under-garments or other articles of clothing, and various other materials which may act as fomites. In one part of the correspondence in the lay press elicited by the British Congress on *Tuberculosis*, to which I have before referred, an attempt was made to fix grave suspicion as a possible source of phthisical infection upon a material much used for the external protection and decoration of humanity named "Harris tweed." I know nothing about the matter personally, but I believe that the defenders of the "tweed" came off victorious, so that any of us who have been accustomed to wear it under any circumstances may "breathe again." The stuffing of dolls was also vigorously attacked from this point of view, but I think this is rather a "straining at gnats." I have not dealt with the question of tuberculous infection by milk or other kinds of food, as it does not apply directly to thoracic phthisis, and is still unsettled and *sub judice*.

While thus placing the contagious aspect of thoracic phthisis in the forefront, things are not nearly so formidable from this point of view as they appear to be at first sight, and it cannot be too strongly insisted upon that it depends in very large measure upon individuals and communities how far the disease shall prevail, and what ravages it shall make The fact must never be ignored or made light of that there are numerous causes and conditions, call them "predisposing," "favouring infection," or what you will, which hold an important, it may be an essential, relation to the complaint, as etiological factors under various circumstances, and many of which are to a great extent under our control.

I now submit in tabular form a comprehensive arrangement or classification of cases of thoracic phthisis, from a pathological and etiological point of view, which may afford a convenient basis for further discussion.

TABLE I.—*Etiological Classification of Thoracic Phthisis.*

A.—Definite infection from without.
B.—Infection from within—Auto-infection.
C.—Personal inherent predisposition.
D.—Causes acting on general system—Acquired personal predisposition.
E.—External conditions and environment.
F.—Special causes
G.—*Local causes, acting more or less directly on respiratory apparatus.*
H.—Local predisposing morbid conditions.
I.—General or remote predisposing diseases.

I propose to discuss briefly each of the etiological groups mentioned in the foregoing table.

### *A.—Definite Infection from Without.*

The cases which I would place in this group are those in which thoracic phthisis can be distinctly traced to some definite source of infection, there being no personal predisposition or other cause at all noteworthy or evident, and the patient having been previously in sound health. Of these directly infective cases I have met with some striking instances, and they belong to one or other of the following categories.

1. Those originated in the post-mortem room or in the pathological or bacteriological laboratory. Apart from accidental inoculation, I believe that phthisis may possibly arise from inhalation of tubercle bacilli in the course of experimental *investigations or researches*, and I feel sure that it is well to exercise due care when carrying out such investigations in connexion with tuberculous lesions or their organisms.

2. Those in which the infective agent passes directly from individual to individual. Some authorities would place a large proportion of cases in this division, especially as they occur in conjugal and family life. Of course, under such circumstances there would always appear, *à priori*, to be more or less danger of this mode of transmission, but there are generally other factors to be taken into account. My own opinion is that an exaggerated idea of this uncomplicated direct infection is often entertained, and this opinion is supported by the oft-quoted experience of the Brompton Hospital, in relation to the medical staff, residents, and nurses Still, I have met with some very remarkable instances in which it has taken place. It can then be as a rule readily explained by prolonged, intimate, and more or less constant companionship in a small and close room; personal devotion in nursing; and, not uncommonly, frequent kissing Thus phthisis may be conveyed, not only from one member of the family to another, but *from a patient to an individual in no* way related Of this I had a striking example in the case of a young man who was engaged *to* be married, but his intended bride developed consumption. He was in her company a great deal during her illness, and was a "devoted lover" until her death Soon after he was brought to me suffering from rapid and extensive pulmonary tuberculosis.

3. Those in which tubercle bacilli are inhaled in a room, office, workshop, or other place where due care has not been taken with regard to phthisical expectoration, or where proper disinfection after occupation by phthisical patients has not been carried out. How far thoracic phthisis may arise independently and directly in this way must be a matter of speculation, but certainly this mode of infection ought never to be made light of or disregarded. As an illustrative case I may mention that of a young man who was brought to me suffering from pronounced consumption which was attributed to the fact that he had worked at a desk where a clerk had previously worked who died from rapid phthisis. He came from a sound stock, had enjoyed excellent health, had led an active and vigorous life, was quite satisfactory as regards habits in every way, and there appeared no reason whatever why he should have become phthisical, except from this direct infection.

I have seen it stated that no arrangements are made in post-offices in this country as regards expectoration, while in addition their want of ventilation and other sanitary defects are but too evident. Consequently phthisis from direct infection is highly probable under such circumstances, and the mortality from this disease amongst the employés in these offices is stated to be decidedly high, to say nothing of dangers to the public.

### *B.—Infection from Within—Auto-Infection.*

That thoracic phthisis may be secondary to a tuberculous lesion in some other part of the body is well known and acknowledged in a general kind of way, but my belief is that the actual facts bearing upon auto-infection are by no means adequately recognised or appreciated. It has appeared to me that in some instances of this kind tubercle bacilli are not the only infective agents, but that pyogenic organisms have also to be taken into account. This auto-infection may apparently be quite independent or accidental; but in other cases it is started or brought out by some more or less definite cause, it may be very slight or quite trivial, or by operative procedures for the cure or removal of tuberculous lesions or their effects. And here it may be noted that the question of infection by food may, from this aspect, have a practical though indirect bearing upon the development of thoracic phthisis, inasmuch as the primary mischief may have thus been originated. Direct local infection through the genital system has also to be borne in mind. In other cases such mischief may not have been primarily tuberculous, but has been the result of injury or of inflammatory changes of low or suppurative type, the tuberculous infection being secondary.

Coming to the sources of auto-infection in the causation of thoracic phthisis, I should very much have liked if I could have discussed at some length this aspect of my subject. On the present occasion, however, I can only enumerate the primary lesions which I have found to be practically worthy of consideration, excluding the possible manifestation of active thoracic tuberculosis as a development under favourable conditions of latent congenital infection by tubercle bacilli, through the medium of the blood-current or in other ways, which in my opinion is highly probable within certain limits. These lesions are:—1. Affections of the absorbent glands in the vicinity of the chest, especially in the neck and axilla, the thoracic disease being due either to direct extension or to infection through the lymphatic vessels. 2. Diseases of bones or joints, often of traumatic origin, and the suppurative or ulcerative lesions associated therewith. In this connexion I must particularly mention disease of the lower jaw, sometimes following injury from tooth extraction, of which I have met with some very definite examples. More commonly, however, the mischief is quite remote. 3. Affections of the throat, tonsils, naso-pharynx, or nasal cavities. I feel that I am trenching here on difficult ground, but there can be no doubt as to the presence, not uncommonly, of tubercle bacilli, or organisms resembling them, in these parts, as well as of non-tuberculous lesions of a possibly infective character, and experience has taught me to be on my guard against them in relation to thoracic phthisis, especially if there are chronic so-called scrofulous conditions. 4. Ischio-rectal abscess and subsequent fistula in ano. I regard these conditions as most important foci of auto-infection in relation to thoracic phthisis, of which I have met with many conspicuous examples, and anything of this nature ought to be always regarded as a source of serious danger in individual cases, which calls for efficient operative treatment as a preventive measure. 5. Other more definite tuberculous lesions affecting structures outside the chest, especially abdominal. Thus thoracic phthisis may follow such disease of the intestines, not forgetting the appendix vermiformis; the peritoneum (no doubt in some cases by direct extension through the diaphragm); the lacteal glands; the urinary system; the prostate gland; the sexual or generative apparatus in males or females; and the suprarenal capsules. Tuberculous affections of the skin may also be noticed here. As regards the intestines, I have been much surprised at the statement of Koch and others that primary implication of these structures is rare, as I have met with several very definite cases of this nature. 6. Latent foci of infection within the chest. Cases originating from such foci may be fairly recognised as a definite group due to auto-infection. It is a well-known fact that the quiescent remains of a former limited phthisical lesion are often found post mortem, of which there is no history whatever, or it has only been suspected, or if detected has been arrested and cured. Again, there may be the remnants of a pleurisy, or the mediastinal glands may be infected with tubercle bacilli or be the seat of definite tubercle or its products, of which we know nothing. Under these circumstances some cause, it may be a very slight and inadequate one, such as a chill, starts an active process, which may end in very rapid and grave tuberculosis, involving different structures within the chest.

### *C.—Personal Inherent Predisposition.*

It requires some courage nowadays even to hint that consumption is not altogether a matter of organisms and infection, and especially that there is any inherent personal tendency to the complaint. I congratulate Sir Dyce Duckworth on the admirable address which he delivered before the Liverpool Medical Institution on Oct. 24th, 1901, on "The Personal Factor in Tuberculosis," in which he stuck up manfully for the "host," and on the discussion which it elicited. I desire to support him in a mild and humble sort of way, and to bring before you prominently what experience has taught me with regard to personal intrinsic conditions as predisposing to thoracic phthisis. It is not necessary to refer particularly to race, sex, or age, except to observe that thoracic phthisis may be met with in very young subjects, as well as in old people.

1. *Heredity.*—It must be well known to you all that for a considerable time the idea has been gaining ground that the old notion of the hereditary character of consumption was entirely wrong, and not a few in our profession support this idea in the most aggressive and dogmatic fashion, looking almost with contempt upon anyone who is in any degree of the contrary opinion. The late Sir Richard Thorne, shortly before his lamented death, in an address on "The Prevention of Consumption," which contained much valuable advice, if it could only be carried out, used very strong language on this point, urging his hearers not to "go on believing the lie that consumption ran in families." Koch, at the Congress on Tuberculosis, made this statement: "It has been demonstrated by thorough investigation that, though hereditary tuberculosis was not absolutely non-existent, it was, nevertheless, extremely rare, and we were at liberty in considering our practical measures to leave that form of origination entirely out of account." When an overwhelming authority speaks thus, *ex cathedrâ*, what can one say? And yet I venture to affirm that it is a most dangerous doctrine. Of course, the influence of heredity has been greatly exaggerated in times past, and a large proportion of cases attributed to this cause were merely the result of infection associated with family life. But I have seen too much of hereditary tuberculosis and phthisis under a variety of circumstances where the patients were not exposed to any possible infection beyond what falls to the common lot to allow myself to shut my eyes to the fact that it is an etiological factor which ought never to be disregarded or made light of, from different points of view. I do not mean to say that the occurrence of a single case of consumption in a family, or still more in some collateral relative, implies heredity, but the probability of the transmission of the complaint in this way is increased in proportion as it seems to run in a family, particularly through succeeding generations, or if the predisposition exists on both sides.

Now I do not wish to make too much of this question of heredity, and it is decidedly necessary to warn people, on the other hand, against supposing that, because they come from a sound stock they are therefore in little or no danger of becoming phthisical, and can take any liberties they please with their health It is a well known fact that a considerable proportion of individuals who suffer from consumption have no hereditary tendency to the complaint whatever, so far as can be ascertained, though I have reason to know that statistics and statements on this point cannot be implicitly relied upon

There are several interesting practical questions relating to the hereditary aspect of phthisis but I cannot discuss them on the present occasion, and I will only mention the fact that often there is nothing in the general appearance, physiognomy, or conformation of the individual, or any obvious structural or other peculiarities, which indicate such predisposition Indeed, what has struck me is the number of instances in which before the development of the complaint the patient has been healthy in all respects, well nourished, or even strong and robust, while he may have been active, perhaps too active in games, athletics, sports and the like, and yet without any special exposure to infection he becomes consumptive It may also be noted on the other hand, that young subjects with a strong hereditary taint, and obviously delicate, may, by proper management develop into healthy individuals, and never have any tuberculous mischief

2 *Diathesis and temperament* —I take it for granted that you are all familiar with the characters which have been attributed to the "tubercular' and 'scrofulous or strumous" diathesis respectively, and to which at one time, considerable importance was attached In my experience it certainly has not been common to find persons not actually suffering from tuberculosis in some form who correspond in any marked degree with the classical description of the tuberculous diathesis, but, still, it is sometimes observed in a pronounced form

The scrofulous diathesis is much more frequently met with, but Sir Dyce Duckworth, in the address to which I have already referred strenuously opposed the modern doctrine that "scrofula is tuberculosis," and maintained that it was possible to be scrofulous throughout life without becoming tuberculous I am inclined to agree with him, but on the other hand, those persons whom we are accustomed to describe as "strumous or 'scrofulous' are certainly predisposed in a marked degree to tuberculosis and to thoracic phthisis for reasons which can be easily explained In my experience temperament has not appeared to have much if any, influence in relation to the disease, nor have I been able to associate with it any particular facial physiognomy

3 *Bodily conformation and general condition* —The majority of persons who become phthisical are of a very ordinary type and many are in every way quite up to the average standard as regards conformation and general condition Not a few, indeed are models of health and it is an important practical point that no individual is safe however robust he may be, and however free from any hereditary taint At the same time the predisposition to the disease is decidedly increased in subjects who are naturally "delicate of slender build and feeble constitution with signs of textural frailty quite apart from heredity, and one always feels anxious about young persons who are pale thin, and anæmic and especially if they grow rapidly to an unusual height without corresponding development of the bodily frame My experience is quite in accord with that of Dr James E Pollock as to the comparative infrequency of phthisis among chlorotic females though of course it is dangerous to assume such immunity in any individual case

### *D —Causes Acting on the General System—Acquired, Personal Predisposition*

Now we come to one of the most formidable and often sad aspects of the etiology of thoracic phthisis and that is to consider the causes or conditions more immediately associated with the individual and his mode of life which are such potent factors in producing what may be termed an "acquired predisposition' They not only lower or depress the system generally but render the local structures much less able to resist the pathogenic action of the invading organisms The causes are but too well known and they make one almost despair of producing any marked or lasting effect upon the prevalence of consumption There are certain special factors belonging to this category which have however, a wider influence and to these more particular reference will be made later Although they are quite familiar it may be well to mention prominently, without entering into any details the general nature of the causes which come under this head and they may be grouped as follows —

1 Insanitary conditions and surroundings, as regards overcrowding habitual want of ventilation entire absence of sunlight close confinement in a used up or even foul atmosphere want of cleanliness both personal and domestic, and in short often an entire neglect of all recognised sanitary or hygienic regulations which affect the general health This is further frequently associated with cold, damp insufficient clothing and other distressing accompaniments of poverty

2 Deficiency of proper nutriment either as regards quantity or quality of food, or both, from an inability to obtain it—in a word from various degrees of starvation—especially in young and growing subjects or because the individual is unable or unwilling to take sufficient or suitable diet, or from neglect of proper meals Phthisis may supervene in cases of so called "anorexia nervosa", and I have certainly known the disease to be promoted by religious fasting The want of good milk is in my opinion, notwithstanding the dread of infection a powerful cause of the tendency to tuberculosis in children

3 Intemperance, and various other injurious habits, as well as faulty modes of living Among these may be mentioned want of exercise or of any active out door life, or on the other hand, frequent excessive exertion and fatigue, late hours, with their almost inevitable accompaniments which are such a common feature in modern social life, sexual excesses or masturbation, and in not a few instances an utter disregard of all "rules of health," culminating in what I may term "general debauchery," the effects of which in helping to develop thoracic phthisis are but too manifest Alcohol will be separately considered.

4 Occupation, which is another of the causes to be referred to separately

5 Conditions which occasion a frequent or more or less constant drain upon the system often accompanied with want of adequate or proper nourishment, and other factors detrimental to health, especially rapid child bearing and prolonged lactation and probably menorrhagia in some cases A chronic non tuberculous diarrhœa may be followed by phthisis

6 Mental depressing causes of various kinds I feel sure that causes coming under this category do not always receive the attention they deserve as factors predisposing to tuberculosis Undoubtedly excessive mental work or study may have more or less influence, especially when associated with other causes Other depressing factors associated with the nervous system are prolonged worry or anxiety, profound and lasting grief pronounced and persistent lowness of spirits or melancholia the shock and depression or other effects produced by sudden and unexpected loss of fortune or other social reverse and now and then disappointed affection or ambition The frequent occurrence of phthisis amongst those mentally affected is well known but here various causes are usually at work.

### *F —External Conditions and Environment*

Under this head come the questions relating to climate, season temperature meteorological changes, soil, altitude, locality residence and its surroundings and allied conditions as predisposing to thoracic phthisis That these factors have considerable and widespread influence cannot be doubted and it is well to recognise them to the fullest extent though of course being prepared to meet with the disease under all possible circumstances even in the higher altitude which ought to be exempt This aspect of the subject is well understood and it is adequately dealt with in text-books and special works on consumption though I have noted in some quarters a tendency to throw doubt upon certain views commonly entertained In this country we are all but too familiar with the meteorological conditions and changes and other factors which depress the general system and at the same time tend to damage our respiratory structures We have one advantage over some of the warmer and drier climates in that the tubercle bacilli in sputum have as a rule not such a chance of drying rapidly and becoming diffused through the atmosphere and to a certain extent therefore we may be in less danger of infection, though on the other hand we have during the greatest part of the year no powerful sunshine to destroy them The question of soil is an important one not only in its more or less wide scope but also in relation to particular residences

The late Sir Richard Thorne, in the address to which I have before referred, affirmed in regard to the prevention of phthisis that nothing would do good unless people refused to live on a damp sub-soil. The beneficial effects of efficient drainage as a preventive measure have been demonstrated in several instances and are always worthy of attention, though they have not proved so permanently useful in some localities as was anticipated at first.

### *F.—Special Causes.*

There are three factors which stand out so prominently in their etiological relation to thoracic phthisis, while often acting more or less together, and which are so much under our control, that they demand special notice—namely, *air*, *alcohol*, and *occupation*. An entire lecture might easily be devoted to these factors, but I can only refer to them very briefly.

*Air.*—The injurious effects upon the respiratory organs which the air we breathe is capable of producing are obvious enough, and, theoretically at least, they appear at the present day to be widely, if not almost universally, recognised and appreciated. Indeed, fresh air and plenty of it is now the popular cry everywhere. and the "open-air" treatment holds the field, and. as one authority says, "has come to stay." The idea is by no means new or of modern growth, as many seem to imagine, for writers have insisted upon it long ago. Amongst others the late Dr. MacCormac of Belfast, the illustrious father of an illustrious son, strenuously insisted upon the dangers of "re-breathed" air in relation to consumption. The New Sydenham Society has recently republished a remarkable essay on "The Treatment and Cure of Pulmonary Consumption" by Dr. George Bodington, a general practitioner at Sutton Coldfield, who died on Feb. 5th, 1882, in his eighty-third year. This essay was first published in 1840. Dr. Bodington certainly appears to have been the originator of the modern "open-air treatment" in its main essentials, and he particularly advocated the advantages of pure, dry, "frosty" air. He earnestly protested against keeping consumptives closely and carefully confined, as was then the practice, as "forcing them to breathe over and over again the same foul air contaminated with diseased effluvia of their own persons."

The ways in which the inspired air may be injurious are various, such as by conveying infection, lowering the general tone and resisting power of the individual, irritating the respiratory passages, and so on, but I cannot enter into details on this point. But coming to the practical aspect of the matter, what is the actual state of things even now with regard to the air we are obliged to breathe under various circumstances? Well, I think it is about as bad as it can be, not only in our large cities and towns but everywhere To say nothing of the conditions under which the working classes, and especially the poorer members of the community, are compelled to live and work, the idea of the necessity of fresh air and good ventilation is by no means carried out in practice in the homes of the so-called "middle" and "upper" classes in anything like the degree in which it ought to be, and I really think that medical men are sometimes the worst offenders in this respect. Then go into almost any shop or office, and you can seldom fail to be oppressed with the feeling of "stuffiness" and "used-up air." I have already alluded to post-offices, and amongst other really dangerous places may be mentioned courts of justice, where recently some of our judges have been seriously affected by the vitiated air; places of public entertainment, in some of which things are made far worse by the modern practice of permitting smoking, the atmosphere being often thus rendered absolutely irrespirable; churches and chapels; restaurants or dining-saloons; and railway-carriages or other public vehicles When you are half stifled with the foul atmosphere, try to open a window, and you will soon find what people think of fresh air and ventilation. But bad as things are in this country my experience is that they are far worse on the continent, where everybody is supposed to be so advanced in all kinds of scientific knowledge and practice, and where the "open-air" treatment is so flourishing In short, while there is so much talk about the imperative necessity of proper ventilation, fresh air, open air, and the like, as a matter of fact the large majority of people are still living more or less constantly in an impure or foul atmosphere, often from choice, which cannot but have a widespread and powerful influence in the production and propagation of thoracic phthisis.

*Alcohol.*—The evil effects of intemperance in the use of alcohol in relation to thoracic phthisis are appalling and incalculable. Not only does this factor act as a powerful predisposing cause in starting the disease in different ways, but it is often continued during its progress, thus helping seriously to promote its activity and to hasten its course. In his address at the Congress on Tuberculosis on "The Prevention of Consumption," Brouardel said that "alcoholism is the most potent factor in propagating tuberculosis," and "any measures, state or individual, tending to limit the ravages of alcoholism, will be our most precious auxiliaries in the crusade against tuberculosis." Dr. J. F. W. Tatham has shown by his statistics the connexion between occupation as affording temptations or opportunities for indulgence in drink, and the mortality from phthisis. Indeed, its effects are but too evident on all hands, and create a feeling almost of despair.

*Occupation.*—This etiological factor also accounts for an enormous number of cases of thoracic phthisis, directly or indirectly, and it acts as a rule in more ways than one. Indoor occupations often expose individuals to almost every possible anti-hygienic condition that can be imagined, including the habitual inhalation of a close, used-up, or foul atmosphere for long hours, and frequently accompanied with bad living. Then the dangers of infection are commonly very considerable, even when precautions are taken, which, however, are still much neglected. On the whole, outdoor occupations are much more favourable, except in so far as they entail exposure to cold and wet, to marked changes of temperature, or to the vicissitudes of weather, which tend to affect the respiratory organs. No doubt, however, individuals can efficiently harden themselves in a rational way against such causes. Other injurious aspects of occupation are that it frequently involves the direct inhalation of irritant particles; hard physical work, or working in certain postures, which tends to damage the thoracic structures; mental strain or anxiety, or worry; or the dangers of alcoholism already referred to.

### *G.—Local Causes.*

The injurious effects of different causes connected more immediately with the chest or respiratory organs, as factors in the development of thoracic phthisis, do not, judging by my own observation, as a rule receive the consideration which they deserve, and I desire to draw special attention to the following points.

1. Although a large proportion of phthisical patients start with a chest quite up to the average in conformation and capacity, still it is obvious that the more contracted and ill-developed this region is, the worse must it be for the lungs, and the more likely are they to become damaged. The different forms of so-called "phthinoid" chest are well known. I cannot doubt for a moment, further, that habitual imperfect use of these organs, or compression of the thorax by belts, tight-lacing, unyielding corsets, and the like, are more or less conducive to phthisis. It may also be associated with various chest-deformities, especially when these are pronounced, though certainly it is remarkable how often persons who present even extreme deformities of this region escape. On the other hand, I have met with a considerable number of cases, particularly among soldiers, where over-training and undue distension of the chest and lungs in subjects unfitted for such development has appeared to me to be a predisposing factor in relation to consumption.

2. Traumatic causes may certainly lead, directly or indirectly, to the development of thoracic phthisis. The lodgment of a foreign body in a bronchus or lung, which cannot be removed by operation, accounts for one very definite class of cases. Blows on the chest, without any obvious injury to the solid framework, and with or without hæmoptysis, may also start the trouble, or render it active in chronic and quiescent cases. A patient of mine, an amateur boxer, who suffered from very chronic phthisis, was struck over the seat of disease in a friendly encounter, which caused profuse hæmoptysis, and from that moment he went rapidly down hill. Traumatic lesions of the thoracic walls, of a more definite and serious nature, such as fractures or gun-shot wounds, may also be followed by consumption. I have seen a remarkable case from time to time during recent years, in which the chest was run over, and whatever actual damage was done at the time, the condition is now one of very definite phthisis affecting the upper part of both lungs.

3. The effects of local irritants, of various kinds and degrees, which are inhaled and thus come into direct contact

with the air-passages or pulmonary structures, are obviously of much moment in relation to the etiology of phthisis. Though some people seem to think that these organs can resist anything except the tubercle bacillus, we cannot ignore the directly injurious effects of very cold or cold and damp air, as well as of an impure atmosphere or one laden with dust, soot, fog, smoke, or what not, with which we are all but too familiar. Dare I venture to hint that even excessive tobacco-smoking is not free from danger from this aspect? The most pronounced and definite causes coming under this category, however, are the easily recognised irritants, either of a chemical nature, or in the form of minute solid particles, the latter being chiefly inhaled in connexion with different occupations, giving rise to the various forms of *pneumoconiosis* or so-called "mechanical phthisis." I have known some very definite cases of thoracic phthisis to originate from inhaling irritant gases in chemical laboratories. The interesting and important fact may be noted here that typical tubercles can be produced even in man by mechanical particles.

4. Another factor which I feel sure is not uncommonly important in relation to the etiology of phthisis, but which is much disregarded, is the act of coughing, especially when severe and persistent, which I believe has a damaging effect upon the apices of the lungs, as well as being injurious in other ways. Such cough is frequently quite independent of pulmonary trouble, being more particularly associated with the throat and main air-passage. In relation to the throat an elongated uvula has to be specially borne in mind, and I have met with very definite cases of irrepressible cough due to this cause, in which well-marked physical signs appeared at one or both apices, but these cleared up completely after removal of the uvula and consequent cessation of the cough. While referring to the throat, it may be also noted that great enlargement of the tonsils as well as adenoids may cause further trouble by obstructing the breathing, thus interfering with the proper use of the lungs and the development of the chest. With regard to the larynx and trachea, apart from actual tuberculous disease, chronic or recurring affections of these parts may certainly promote the development of thoracic phthisis, and even huskiness or hoarseness, and still more cough originating here, should never be neglected. From this point of view, excessive use or straining of the voice, in preaching, public speaking, teaching in schools, singing, or shouting in the streets, as in the case of costermongers, hawkers, cheap-jacks, &c., may indirectly predispose to phthisis.

5. The relation of pulmonary hæmorrhage to thoracic phthisis as an etiological factor cannot, in my opinion, be questioned for a moment, and I fail to see why there should be any difficulty in acknowledging it. We meet with cases of blood-spitting, even in considerable amount, the source of which cannot be located, and in which complete recovery follows with no after ill-effects. When, however, hæmorrhage takes place from some part of a lung, or blood finds its way there from the air-passages, it is very liable to originate further trouble, forming a suitable medium for the growth and multiplication of tubercle bacilli. It is generally assumed that such hæmorrhage always implies previous tuberculous mischief but this is by no means proved. I have met with cases where hæmoptysis resulted from a definite and powerful strain, in connexion with running, swimming, cycling, and different kinds of athletics, or from a blow on the chest, in persons apparently perfectly healthy, and this was followed by acute phthisis, with rapid formation of cavities, or a progressive but slower type of the disease. But even where there has been previous trouble in the lung, which is often evident enough, the occurrence of considerable or continuous hæmoptysis often seems to give it a fresh start, and to make it advance with increasing severity and rapidity.

### *H.—Local Predisposing Morbid Conditions.*

It cannot be too strongly insisted upon that thoracic phthisis is by no means always a primary and independent disease, but is in a fair proportion of cases added to or grafted upon, so to speak, some preceding definite morbid condition within the chest. This fact does not in any way invalidate the tuberculosis theory, or call in question the influence of tubercle bacilli. Indeed, it is generally believed that these organisms cannot do harm unless there has been some lesion which enables them to gain a footing, be it only a slight erosion of the mucous surface or removal of the ciliated epithelium from any cause. The more obvious conditions which from this point of view may help in the development of phthisis may be thus indicated:—

1. Persistent or repeated catarrh of the throat, main air-passages, or larger bronchi.

2. Pronounced chronic bronchitis, usually associated with more or less emphysema. The danger of the supervention of tuberculosis in cases of this kind should always be borne in mind; and I emphatically affirm, from much personal observation, that phthisis is not uncommon in cases of extensive or even extreme emphysema. It may also follow bronchiectasis. Not a few "asthmatic" cases become phthisical sooner or later.

3. Pneumonia of different kinds. The general view is that any case of pneumonia which, either speedily or gradually, turns out to be phthisical, is really tuberculous from the outset. While, no doubt, this is true as a rule, I can see no reason why a pneumonic condition not originally tuberculous may not become infected, especially if the morbid products remain long unabsorbed. In certain cases of so-called "fibroid phthisis" there is unquestionably no tubercle at first, though this may develop subsequently.

4. Pleuritic conditions. The relation of pleurisy to thoracic phthisis is a very important and interesting problem, to which I shall again have to refer in another connexion. I do not at all agree with the opinion now very widely entertained that the large majority, or as some think, practically all cases, of pleurisy with effusion are essentially tuberculous. That phthisis often develops in course of time in such cases is another matter, though the statistics on this point differ considerably. I have followed a large number of cases for many years where there have been no after-effects of this kind and the patients still enjoy excellent health. My explanation of the frequent occurrence of phthisis after pleurisy, sooner or later, is that no proper care has been taken to prevent the formation of firm and thick adhesions or to expand the lung properly, and in this view I believe that I am supported by Koch. Similar adhesions form occasionally after dry pleurisy, and they are also often left after pneumonia. Of course, if unabsorbed morbid products remain in the pleural cavity the danger is still greater. Remarkable extensive adhesions sometimes form very slowly and insidiously, even on both sides, and I have known phthisis to develop in such cases. However we look upon this question, there can be no doubt as to the practical relation of pleurisy and its effects to thoracic phthisis as etiological or pathological factors of considerable importance, favouring the action of tubercle bacilli or other organisms.

There is another class of cases to which I must allude here, for I feel sure that the condition does not uncommonly lay the foundation for apical phthisis, but is seldom recognised—namely, those in which there is a firm adhesion at the apex of the lung, binding it down, usually on the right side, due to hard manual work or other causes producing local irritation. I have a strong impression that many of the cases of "cured" phthisis at an apex are of this nature originally, the condition favouring the invasion of organisms.

Phthisis may follow non-tuberculous empyema, especially if it bursts into the lung or is not efficiently treated by operation. This mode of origin of the complaint is, however, comparatively exceptional in proportion to the number of cases of empyema which are met with in practice.

5. Pressure upon or other obstruction of the trachea or of a main bronchus. The pulmonary changes which are likely to follow difficulties of this nature may certainly lay the foundation for phthisis and are very favourable to infection. In this way the complaint may complicate aneurysm, mediastinal tumour, enlargement of the bronchial glands, not necessarily tuberculous, syphilitic changes involving the air-passages, and other conditions. Aneurysm has also been supposed to help in the development of phthisis by reducing the activity of the pulmonary circulation.

6. Miscellaneous conditions. Under this head it will suffice to note that thoracic phthisis, of a tuberculous nature, may supervene upon syphilitic lesions in the lung, pulmonary abscess or growth, abscess opening into the lung from the abdomen, hydatids, congenital disease of the pulmonary artery, and possibly actinomycosis.

### *I.—General or Remote Predisposing Diseases.*

An important group of cases of thoracic phthisis is that in which the complaint is set up in connexion with certain acute diseases, usually as a sequel; or which supervene in the course of chronic general morbid conditions or particular complaints, having nothing whatever to do directly with tuberculosis or with the chest. Its well-known relation to measles, whooping-cough, and influenza is readily explained; and it also occasionally follows enteric fever or other acute specific diseases. I feel sure that the constitutional condition produced by congenital syphilis sometimes predisposes to thoracic phthisis, of a pronounced tuberculous type. Amongst other diseases with which it may be associated as a secondary event it will suffice to mention diabetes, prolonged indigestion or definite affections of the alimentary canal interfering with the consumption or assimilation of food, gastric ulcer, hepatic cirrhosis, chronic Bright's disease, arterio-sclerosis, chronic cardiac disease, and various nervous diseases, especially the different forms of sclerosis of the nerve centres.

On the other hand, certain conditions are believed to be antagonistic to tuberculosis, but to these time forbids me to refer, except to say that I by no means agree with all that is stated on this point. Sir Dyce Duckworth is strongly of opinion that persons of gouty predisposition are largely immunised against tuberculosis; and that when this lesion occurs in the gouty its course is much modified, as it makes but little progress as a rule, tends to obsolescence, and fibrotic changes are prominent. I believe that there is a sound foundation for these statements.

*Combination of causes.*—I have endeavoured in the preceding discussion to indicate in a practical manner what I believe to be the important individual factors in originating and promoting the development of thoracic phthisis. In the large majority of cases, however, these are combined in various ways, and unfortunately we often have to deal with numerous and diverse causes, acting in concert. Hence it is easy to understand why the complaint is so much more prevalent in large cities and towns, especially in their more crowded and poorer districts; in localities where there are numerous and extensive manufactories of different kinds; and among communities gathered together in large numbers in various institutions, which I need not enumerate. Phthisis is, however, but too prevalent in the smaller towns and villages, as well as in country districts, where tiological conditions are much less complicated. ver. it is *not uncommon* even in houses and homes may be quite isolated, and to all appearance under favourable circumstances from a sanitary point of view. course, climate and season have often considerable luence in such cases; but we have also to bear in mind rticularly the dangers of preventable infection, hereditary endency, and acquired predisposition, which is unfortunately ut too frequently due to habits.

As a rule, it is not possible to refer the onset of thoracic phthisis to any distinct and recognisable *exciting cause.* Reference has been made to certain modes of origin of the disease which might come under this category, such as when it follows an acute illness, or results from injury or accidental hæmorrhage. I would here, however, warn against the modern tendency to ignore altogether the old-fashioned ideas as to the danger, from the aspect of exciting causes, of getting wet through and remaining in wet clothes; chill of any kind, but especially when perspiring, even in the summer; exposure to cold and damp air, or to certain winds; inclement seasons; defective clothing, and the like. These may set up an acute affection of some part of the respiratory apparatus, which, if not phthisical from the first, becomes so later. Nor is it safe to make light of even a "slight cold," which, if neglected, may undoubtedly lay the foundation for this complaint.

The preventive treatment of thoracic phthisis can only be rationally founded on a full and comprehensive knowledge and appreciation of its pathology and etiology in all its details. The tendency nowadays is unquestionably to take a narrow, incomplete, often entirely one-sided view of this aspect of the subject, and to lose sight of many important causes or conditions which ought never to be forgotten or overlooked. Unfortunately, when we come face to face with the problems we have to grapple with, our difficulties begin, and I must honestly say that, humanity and the inevitable conditions of life and of so-called civilisation being what they are, I cannot share in the extraordinarily hopeful views now so widely entertained and so freely expressed as to the final eradication and extermination of this "terrible scourge." Still, we can do a great deal as a profession, if we work on intelligent and practical lines. Obviously the prevention of infection is of first importance, and in relation to this question I will only say on the present occasion that I should like to see far more stringent measures taken with regard to the disgusting habit of spitting in public places; that I consider it much safer to destroy by fire all phthisical sputum, when this is practicable, rather than merely to disinfect it; and that I am strongly in favour of voluntary notification of cases of phthisis.

# NOTES ON THE TREATMENT OF FURUNCULOSIS, SYCOSIS, AND ACNE BY THE INOCULATION OF A STAPHYLOCOCCUS VACCINE,

## AND GENERALLY ON THE TREATMENT OF LOCALISED BACTERIAL INVASIONS BY THERAPEUTIC INOCULATIONS OF THE CORRESPONDING BACTERIAL VACCINES.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY.

THE circumstance that inoculation against pyogenic bacteria has not, up to the present, been resorted to would seem to be due to the fact that our range of thought is in this, as in every other direction, limited by pre-suppositions. The following are among the pre-suppositions which are current in connexion with inoculation. 1. Since methods of inoculation find their special sphere of application in connexion with septicæmic diseases there would be little prospect of a useful application of such methods in connexion with any local invasion of the tissues by pyogenic bacteria. 2. Since pyogenic micro-organisms can always be held off from operation wounds by a rigid observance of aseptic precautions there would be no prospect of a useful application of inoculations such as we have here in view in connexion with operative procedures. 3. Since bacterial invasions of the skin and mucous membranes can be dealt with by the application of chemical antiseptics a resort to inoculations directed against the invading bacteria would here also be out of place. 4. Inoculations with vaccines can be of avail only when they forestall infection. 5. Where a vaccine containing toxic bacterial products is introduced into the organism of a patient who is already infected this must inevitably be followed by an aggravation of that patient's condition.

Let us take the above assumptions in order and see how far each of them is justified.—The first assumption can be disposed of in a few words. It is in point of fact merely the expression of the belief of a period when inoculation—using the term in its widest sense—had as yet been applied only in connexion with the prophylaxis of small-pox. Since the period in question methods of inoculation have, as reflection will show, been successfully applied in connexion with almost every form of bacterial invasion.—In connexion with the second assumption it will suffice to remark that even assuming that inoculations against pyogenic bacteria would fail to find any useful application in connexion with operative procedures, such inoculations might conceivably render service in connexion with bacterial invasions of the skin and mucous membranes.—The next assumption—to wit the assumption that bacterial invasions of the skin and mucous membranes can be dealt with by the application of chemical antiseptics—altogether ignores the defects and limitations of this method of treatment. These defects and limitations—already fully realised in connexion with the treatment of operation wounds—are, (*a*) the injury to the tissues inflicted by the antiseptic; (*b*) the difficulty of destroying bacteria which have penetrated below the surface; (*c*) the difficulty of applying the antiseptic over the whole affected area in such a manner as to make an end once for all of the invading bacteria; and (*d*) the difficulty of preventing the re-invasion of the disinfected from the neighbouring still infected areas. Let us note that, assuming that it were found possible to inoculate in such a manner as to call into action the defensive powers of the organism, all these difficulties would have been effectually overcome.—We next pass on to consider how far we can uphold the assumption that inoculations with bacterial vaccines must be unavailing unless where they forestall infection, and the further assumption that inoculations of sterilised bacterial cultures—i.e., inoculations which involve the introduction of toxic bacterial substances into the organism—are necessarily with the air-passages or pulmonary structures, are obviously of much moment in relation to the etiology of phthisis. Though some people seem to think that these organs can resist anything except the tubercle bacillus, we cannot ignore the directly injurious effects of very cold or cold and damp air, as well as of an impure atmosphere or one laden with dust, soot, fog, smoke, or what not, with which we are all but too familiar. Dare I venture to hint that even excessive tobacco-smoking is not free from danger from this aspect? The most pronounced and definite causes coming under this category, however, are the easily recognised irritants, either of a chemical nature, or in the form of minute solid particles, the latter being chiefly inhaled in connexion with different occupations, giving rise to the various forms of *pneumoconiosis* or so-called "mechanical phthisis." I have known some very definite cases of thoracic phthisis to originate from inhaling irritant gases in chemical laboratories. The interesting and important fact may be noted here that typical tubercles can be produced even in man by mechanical particles.

4. Another factor which I feel sure is not uncommonly important in relation to the etiology of phthisis, but which is much disregarded, is the act of coughing, especially when severe and persistent, which I believe has a damaging effect upon the apices of the lungs, as well as being injurious in other ways. Such cough is frequently quite independent of pulmonary trouble, being more particularly associated with the throat and main air-passage. In relation to the throat an elongated uvula has to be specially borne in mind, and I have met with very definite cases of irrepressible cough due to this cause, in which well marked physical signs appeared at one or both apices, but these cleared up completely after removal of the uvula and consequent cessation of the cough. While referring to the throat, it may be also noted that great enlargement of the tonsils as well as adenoids may cause further trouble by obstructing the breathing, thus *interfering with the proper use of the lungs and the development of the chest.* With regard to the larynx and trachea, apart from actual tuberculous disease, chronic or recurring affections of these parts may certainly promote the development of thoracic phthisis, and even huskiness or hoarseness, and still more cough originating here, should never be neglected. From this point of view, excessive use or straining of the voice, in preaching, public speaking, teaching in schools, singing, or shouting in the streets, as in the case of costermongers, hawkers, cheap-jacks, &c., may indirectly predispose to phthisis.

5 The relation of pulmonary hæmorrhage to thoracic phthisis as an etiological factor cannot, in my opinion, be questioned for a moment, and I fail to see why there should be any difficulty in acknowledging it. We meet with cases of blood-spitting, even in considerable amount, the source of which cannot be located, and in which complete recovery follows with no after ill effects. When, however, hæmorrhage takes place from some part of a lung, or blood finds its way there from the air-passages, it is very liable to originate further trouble, forming a suitable medium for the growth and multiplication of tubercle bacilli. It is generally assumed that such hæmorrhage always implies previous tuberculous mischief but this is by no means proved I have met with cases where hæmoptysis resulted from a definite and powerful strain, in connexion with running, swimming, cycling, and different kinds of athletics, or from a blow on the chest, in persons apparently perfectly healthy, and this was followed by acute phthisis, with rapid formation of cavities, or a progressive but slower type of the disease. But even where there has been previous trouble in the lung, *which is often evident enough, the occurrence of considerable* or continuous hæmoptysis often seems to give it a fresh start, and to make it advance with increasing severity and rapidity.

### II.—*Local Predisposing Morbid Conditions.*

It cannot be too strongly insisted upon that thoracic phthisis is by no means always a primary and independent disease, but is in a fair proportion of cases added to or grafted upon, so to speak, some preceding definite morbid condition within the chest. This fact does not in any way invalidate the tuberculosis theory, or call in question the influence of tubercle bacilli. Indeed, it is generally believed that these organisms cannot do harm unless there has been some lesion which enables them to gain a footing, be it only a slight erosion of the mucous surface or removal of the ciliated epithelium from any cause. The more obvious conditions which from this point of view may help in the development of phthisis may be thus indicated:—

1. Persistent or repeated catarrh of the throat, main air-passages, or larger bronchi.

2. Pronounced chronic bronchitis, usually associated with more or less emphysema. The danger of the supervention of tuberculosis in cases of this kind should always be borne in mind; and I emphatically affirm, from much personal observation, that phthisis is not uncommon in cases of extensive or even extreme emphysema. It may also follow bronchiectasis. Not a few "asthmatic" cases become phthisical sooner or later.

3. Pneumonia of different kinds. The general view is that any case of pneumonia which, either speedily or gradually, turns out to be phthisical, is really tuberculous from the outset. While, no doubt, this is true as a rule, I can see no reason why a pneumonic condition not originally tuberculous may not become infected, especially if the morbid products remain long unabsorbed. In certain cases of so-called "fibroid phthisis" there is unquestionably no tubercle at first, *though this may develop subsequently.*

4. Pleuritic conditions. The relation of pleurisy to thoracic phthisis is a very important and interesting problem, to which I shall again have to refer in another connexion. I do not at all agree with the opinion now very widely entertained that the large majority, or as some think, practically all cases, of pleurisy with effusion are essentially tuberculous. That phthisis often develops in course of time in such cases is another matter, though the statistics on this point differ considerably. I have followed a large number of cases for many years where there have been no after-effects of this kind and the patients still enjoy excellent health. My explanation of the frequent occurrence of phthisis after pleurisy, sooner or later, is that no proper care has been taken to prevent the formation of firm and thick adhesions or to expand the lung properly, and in this view I believe that I am supported by Koch. Similar adhesions form occasionally after dry pleurisy, and they are also often left after pneumonia. Of course, if unabsorbed morbid products remain in the pleural cavity the danger is still greater. Remarkable extensive adhesions sometimes form very slowly and insidiously, even on both sides, and I have known phthisis to develop in such cases. However we look upon this question, there can be no doubt as to the practical relation of pleurisy and its effects to thoracic phthisis as etiological or pathological factors of considerable importance, favouring the action of tubercle bacilli or other organisms.

There is another class of cases to which I must allude here, for I feel sure that the condition does not uncommonly lay the foundation for apical phthisis, but is seldom recognised—namely, those in which there is a firm adhesion *at the apex of the lung, binding it down, usually on the* right side, due to hard manual work or other causes producing local irritation. I have a strong impression that many of the cases of "cured" phthisis at an apex are of this nature originally, the condition favouring the invasion of organisms.

Phthisis may follow non-tuberculous empyema, especially if it bursts into the lung or is not efficiently treated by operation. This mode of origin of the complaint is, however, comparatively exceptional in proportion to the number of cases of empyema which are met with in practice.

5 Pressure upon or other obstruction of the trachea or of a main bronchus The pulmonary changes which are likely to follow difficulties of this nature may certainly lay the foundation for phthisis and are very favourable to infection. In this way the complaint may complicate aneurysm, mediastinal tumour, enlargement of the bronchial glands, not necessarily tuberculous, syphilitic changes involving the air-passages, and other conditions Aneurysm has also been supposed to help in the development of phthisis by reducing the activity of the pulmonary circulation

6 Miscellaneous conditions. Under this head it will suffice to note that thoracic phthisis, of a tuberculous nature, may supervene upon syphilitic lesions in the lung, pulmonary abscess or growth, abscess opening into the lung from the abdomen, hydatids, congenital disease of the pulmonary artery, and possibly actinomycosis.

### I.—*General or Remote Predisposing Diseases.*

An important group of cases of thoracic phthisis is that in which the complaint is set up in connexion with certain acute diseases, usually as a sequel; or which supervene in

In a somewhat extensive series of observations—carried out on three samples of the patient's blood and upon 13 control samples of normal blood drawn off from six normal persons—only inconstant and very inconsiderable differences were found between the number of colonies developing in the tubes filled in with three different admixtures particularised above. We are thus entitled to conclude that neither the serum of the patient nor any of the control sera exerted any inhibitory effect upon the growth of the staphylococcus.

*Investigation of the agglutinating power exerted by the serum upon the staphylococcus.*—This was undertaken by mixing together in capillary tubes equal volumes of a suspension of an agar culture of staphylococcus and serum in various dilutions. The observations were undertaken on three different samples of the patient's blood On one occasion only was a sedimentation obtained, and this was obtained only in the two-fold dilution of the serum The sera of four normal men were at the same time examined by the same method. Two of these showed an agglutination reaction in all dilutions up to a 16-fold dilution. The two others showed the reaction only in the two-, four-, and eight-fold dilutions.

*Preparation of the staphylococcus vaccine which was employed in the treatment of the patient.*—Nutrient broth was inoculated with a staphylococcus aureus which had been subcultured from one of the original cultures obtained from the patient. After cultivation for three weeks at a temperature of 37° C. the culture was sterilised by exposure for 20 minutes to a temperature of 65° C. An addition of 0·5 per cent. lysol was made to the sterilised culture. The toxicity of the vaccine was then tested on guinea-pigs. It was found that when the quantum of the vaccine inoculated corresponded to 2 per cent. of their body-weight a moderate amount of œdema and a certain amount of constitutional disturbance were produced.

*Details of the inoculations carried out upon the patient and resulting clinical symptoms.*—On Oct. 25th, 1900, the patient was inoculated subcutaneously in the flank with one cubic centimetre of the above vaccine. Twelve hours afterwards there was considerable headache, the patient's temperature stood at 100·6° F., and considerable redness and tenderness had developed at the site of inoculation. The symptoms had entirely passed off after the expiration of 36 hours. On Nov. 1st 1·5 cubic centimetres of the same vaccine were inoculated. The inoculation was followed by similar but somewhat less severe local and constitutional symptoms. On the 13th 1·5 cubic centimetres of the same vaccine were inoculated. Both the local reaction and the general reaction were very slight, the temperature not rising above 99 4° F.

### DATA OF BLOOD EXAMINATIONS INSTITUTED IN THE PERIOD SUPERVENING UPON INOCULATION.

*Investigation of the agglutinating power exerted by the serum upon the staphylococcus*—A determination of the agglutinating power instituted subsequently to the second inoculation showed that the serum now agglutinated the staphylococcus in all dilutions up to a 16-fold dilution

*Investigation of the growth-inhibiting power exerted upon the staphylococcus.*—An estimation carried out in the interval between the first and second inoculations showed that the serum had not acquired any power of inhibiting the growth of the staphylococcus.

The results of two successive estimations of the growth-inhibiting power instituted soon after the dates of the third inoculation are subjoined in tabular form (Table I ).

TABLE I.—*Estimation of the Growth-inhibiting Power exerted upon the Staphylococcus Aureus by the Blood of Patient 1 soon after his Third Inoculation.*

| Date on which the blood was examined. | Number of colonies of staphylococcus which developed in the capillary tubes filled in each case with 5 c.mm. of a gelatin culture of staphylococcus (previously diluted 100,000 fold and 1,000,000-fold respectively with nutrient gelatin) and | | | | Number of colonies of staphylococcus which developed in control tubes filled in each case with 5 c.mm. of same dilution of gelatin culture and 5 c mm. of sterile broth. | | |
|---|---|---|---|---|---|---|---|
| | 5 c.mm. of patient's serum. | 5 c mm. of a 2-fold dilution of patient's serum. | 5 c mm. of a 4-fold dilution of patient's serum. | 5 c.mm. of an 8-fold dilution of patient's serum | Tube 1. | Tube 2. | Tube 3. |
| Nov 14th, 1900. | 0 | 2 | 5 | 10 | 57 | 22 | 50 |
| ,, 19th ,, | 8 | 7 | 7 | 10 | 29 | 36 | 23 |
| Average ... ... | 4 | 4·5 | 6 | 10 | 36·1 | | |

The results of the estimations set forth above would seem to indicate that the blood of a patient in the period immediately subsequent to inoculation constituted a somewhat unfavourable medium for the development of the staphylococcus. The question as to whether any actual bactericidal action was exerted was unfortunately not determined.

*Clinical history of the patient subsequently to inoculation.*—From the date of the first inoculation in October, 1900, the patient's condition began to improve. With the exception of two small superficial boils which developed between the dates of the second and third inoculations and two further similar small boils which developed in the earlier part of 1901 the patient has been absolutely free from furunculosis. The sycosis, eczema, and the affection of the eyelids also began to mend from the date of the first inoculation; the two former had practically disappeared within a month from the beginning of the treatment. The ophthalmia tarsi lasted a little longer. His face is now, and has for a period of over 12 months been, absolutely clean and free from eruption.

*Data of blood examinations instituted more than a year after the date of the original inoculation.*—Recently the patient's blood has been examined by the method devised by my colleague, Major W. B. Leishman,[8] for measuring the phagocytic power of the blood in vitro. The results of these estimations are subjoined in tabular form (Table II.):—

TABLE II.—*Results of the Estimations of the Phagocytic Power of the Blood of Patient 1 instituted more than 12 Months after the Date of Inoculation.*

| Date on which the blood was tested. | Source and variety of staphylococcus employed. | Average number of staphylococci ingested by each polynuclear white blood corpuscle of the *control* blood. | Average number of staphylococci ingested by each polynuclear white blood corpuscle of the *patient's* blood. | Phagocytic ratio—i.e., the proportion in which the number of staphylococci ingested by polynuclear white blood corpuscles of the *control* blood stood to the number ingested by polynuclear white blood corpuscles of the *patient's* blood. |
|---|---|---|---|---|
| 1901.<br>Dec. 2nd. | Staphylococcus aureus subcultured from Patient 1. | 9·3 | 21·7 | 1 : 2·3̄ |
| ,, 15th. | Ditto. | 6·5 | 9·5 | 1 : 1·45 |
| ,, ,, | Staphylococcus albus subcultured from Patient 3. | 12·2 | 12·9 | 1 : 1·07 |
| 1902.<br>Jan. 23rd. | Ditto. | 32·8 | 35·7 | 1 : 1·07 |

The control blood employed in the three first-recorded estimations was derived from W. B. L.; in the last estimation it was derived from A. E. W.

It will be manifest that the capacity of the patients' white blood corpuscles for ingesting staphylococci—and more particularly for ingesting the variety of staphylococcus with which he had been inoculated—was in each case found to be greater than that of the white blood corpuscles of the normal blood used as a control. These observations—more especially when taken in association with the observations made in connexion with the cases recorded below—lend probability to the assumption that the patient's continued freedom from staphylococcus invasion is the result of the inoculations undertaken

CASE 2.—The patient, an elderly maiden lady, presented associated with risk when undertaken upon patients who are already the subject of the corresponding bacterial infections. Consideration shows that these assumptions express the results of experience derived from an observation of the effect of inoculations undertaken in the case of animals and men when already affected with septicæmic diseases. Confining ourselves to the case of man and to the case of inoculations undertaken with sterilised bacterial cultures, there would, indeed, seem grounds for believing that an aggravation of the patient's condition has in some instances followed in the case where the patient has been inoculated with anti-typhoid[1] and anti-plague[2] vaccine respectively while in the incubation stage of these diseases. But we cannot generalise from such instances. For I have in a previous communication[3] dealing with the changes effected in the blood by anti-typhoid inoculation pointed out that there is an all-important difference between the effects produced respectively by large and small doses of vaccine. It was shown in the paper just referred to (1) that where the dose of bacterial vaccine employed was sufficient to produce marked constitutional symptoms inoculation was followed, first, by a negative phase of diminished bactericidal power—corresponding, it may be presumed, to a phase of diminished resistance—and, then, after an interval of a few days by a positive phase of increased bactericidal power—corresponding, it may be presumed, to a phase of increased resistance; (2) that where the dose of vaccine was such as to produce only very slight constitutional disturbance the negative phase was suppressed, the positive phase being already distinctly marked within 24 hours after inoculation; and (3) that where the dose of vaccine was such as to produce very considerable constitutional disturbance the negative phase was exaggerated and prolonged, while the positive phase was considerably, possibly indefinitely, postponed.

---

[8] Brit. Med. Jour., Jan. 11th, 1902.

Since an essentially similar succession of a negative and a positive phase manifests itself after the inoculation of the toxins of both tetanus and diphtheria and, as we shall see below, also in connexion with the inoculation of staphylococcus vaccine, and since the extent and duration of the phase of diminished resistance are in each case a simple function of the dose administered, it would seem clear that the doctrine of the necessary inefficacy and invariable risk of inoculations undertaken upon patients already infected must be abandoned. Manifestly, inoculation will be associated with risk only where the dose of vaccine employed is such as seriously to diminish the patient's resisting power.

It may be noted here that Mr. Haffkine has from the outset contended that his anti-plague vaccine possesses a power of aborting and diminishing the severity of an attack of plague in the case of any patient who may have been inoculated in the incubation stage of the disease. Mr. Haffkine is entitled to the fullest recognition of the fact that in certain of the cases recently recorded by Miss Corthorn[4] and, it may be presumed, in other cases included in the statistical table published by Major W. B. Bannerman, I.M.S.,[5] the event would appear to have been quite in accordance with Mr. Haffkine's anticipations.

Leaving out of consideration all incidental issues, such as that of the expediency of inoculating in the incubation stage of any septicæmic disease unless with duly reduced doses of a standardised vaccine, let us here concentrate our attention upon the fact that it would seem possible—given the employment of the appropriate dose of a vaccine and given also certain other conditions presently to be considered—to obtain benefit from bacterial inoculations even in the case where the patient is already the subject of bacterial infection. If it holds true that inoculations with bacterial vaccines may upon occasion have a therapeutic value in the incipient stages of bacterial invasions which may afterwards assume a septicæmic form, it must *a fortiori* hold true that inoculations conducted with appropriate doses of bacterial vaccines may render useful services in the case of bacterial invasions which manifest themselves from first to last only in the form of localised inflammatory processes. For—and this is clearly brought out by a comparative study of bacterial disease in animals, as well as by the study of any series of cases of one and the same bacterial infection in man—the localisation and restriction of a bacterial invasion may always be taken as an indication of a relatively high grade of resistance on the part of the infected organism.

If we consider the matter rightly we shall see that the process of bacterial inoculation as applied to a patient who is the subject of a bacterial invasion is, in reality, a process of temporarily taking away from a patient's power of resistance with a view to his receiving back that power with usury. It is, in short, a process of trading upon the patient's balance of resistance. When exploiting the method it will, then, be wise to inform ourselves beforehand concerning the resisting power of the patient. It will be wise, also, before adventuring, to learn what we can about the demands which will be made upon the patient's resisting power by the inoculation of that definite quantum of the bacterial vaccine which we propose to employ.

Having now, so far as I can, made clear the situation, I pass on to set forth the results of some preliminary work recently undertaken in connexion with the therapeutic application of anti-staphylococcus inoculations in the treatment of localised staphylococcus invasions. The vaccines employed consisted in each case of staphylococcus cultures which had been sterilised by heating. The cases, six in number, which are reported below include all that I have treated by this method.

CASE 1.—The patient, a man, 40 years of age, consulted me in September, 1900, with a view to seeing whether anything could be done for him. He had suffered from furunculosis complicated by sycosis and eczema of the face since 1893. In that year, while engaged in clearing out a tracheotomy tube which had been removed from a patient who had been operated upon for acute laryngitis, he accidentally inoculated himself in the forefinger with some of the septic material. In spite of three deep incisions made successively into the finger and the palm of the hand infection spread upwards to the axilla (giving origin there to a bubo) and thence onwards into the blood-stream, setting up high fever and septic peritonitis Since that time the patient, who had not previously suffered in this way, had been afflicted with the disorders referred to above. During the seven years which had elapsed since the onset the patient declared that he had never been free from boils for more than three months consecutively Change of climate, every form of medicinal treatment, and local applications of the most varied description had all failed to afford any permanent relief The patient was now suffering from an exacerbation of his symptoms. Recently he had hardly ever been quite free from styes on the eye and boils. These last apparently occurred in two varieties—small superficial boils taking their origin in the skin on the neck and face, and larger deep-seated boils occurring in the subcutaneous tissue in any and every region of the body. The condition of sycosis was associated with weeping eczema and was best marked on the region of the chin. The infiltration of the deeper layers of the skin was even there relatively inconsiderable. The hair follicles of the eyelashes and eyebrows were affected by an inflammatory process similar to that which was affecting the hair follicles of the beard.

*Data of the bacteriological examination of the contents of the boils.*—A cultivation, made on Sept. 16th, 1900, from a small superficial boil on the face yielded a pure cultivation of the staphylococcus albus. A cultivation made on Sept. 19th from a larger and more deep-seated boil on the forehead yielded a pure cultivation of the staphylococcus aureus. A cultivation made on the 24th from a large boil on the forearm yielded a pure cultivation of the staphylococcus aureus.

*Data of the blood examinations instituted before inoculation.*—A count of the different varieties of white corpuscles showed these to be present in the blood in normal proportions. A measurement[6] of the alkalinity of the serum showed a normal degree of alkalinity : $\frac{N}{35}$.

*Estimation of the inhibitory power exerted by the serum on the growth of the staphylococcus.*—Comparative counts[7] were made of the number of staphylococcus colonies which developed in a series of measured volumes of gelatin culture mixed (*a*) with sterile broth, (*b*) with serum derived from normal men, and (*c*) with serum derived from the patient.

[6] The technique employed was that described by me in THE LANCET of Sept. 18th, 1897, p 719

[7] The technique employed was that described by me in THE LANCET of Dec. 1st, 1900, p 1556.

and the ear. The general health also is said to have markedly improved and the patient was able to go about and to enjoy life. Two months from the date of the first inoculation the patient presented herself for examination. She had not had any recurrence of the boils but had been troubled by a few irritable pimples on the hands. A sample of blood having been withdrawn from the finger an estimation of the phagocytic power of the blood was undertaken. The results of the estimation are subjoined (Table V.).

In view of the result of this estimation the patient was warned that a recurrence of the boils must probably be anticipated. After a free interval of three and a half months the patient early in January, 1902, developed a deep-seated boil. This last ran a similar course and was attended by as much pain as the deep-seated boils which had occurred before the date of inoculation. The patient was seen again on Jan. 28th, 1902 Her condition was then quite satisfactory, but she still suffered from occasional irritable pimples. An estimation of the phagocytic power of the blood carried out at room temperature gave the following results: average number of staphylococci ingested by a white blood corpuscle of a normal blood,[13] 4 6; average number ingested by a white blood corpuscle of the patient's blood, 3 5. The proportion of staphylococci ingested by normal blood to staphylococci ingested by patient's blood was thus 1 : 0 75

On March 17th the patient reported that she had no recurrence of the boils and that she was no longer troubled with pimples.

CASE 3.—The patient, a medical man, about 30 years of age, presented himself for treatment on Dec. 6th, 1901. He had suffered continuously for the previous 12 months from small but very irritable pustular pimples and superficial boils on the back of the neck. He was still suffering in this way. A cultivation made from one of his boils yielded a pure cultivation of staphylococcus albus.

### DATA OF BLOOD EXAMINATIONS INSTITUTED BEFORE INOCULATION.

A count of the different varieties of white blood corpuscles showed that the relative numbers were as follows: eosinophil, 1 per cent.; polynuclear, 53 per cent.; basophile, 1 per cent.; and large mononuclear and lymphocytes, 45 per cent. In an estimation of the phagocytic power of the blood the following results were obtained:—

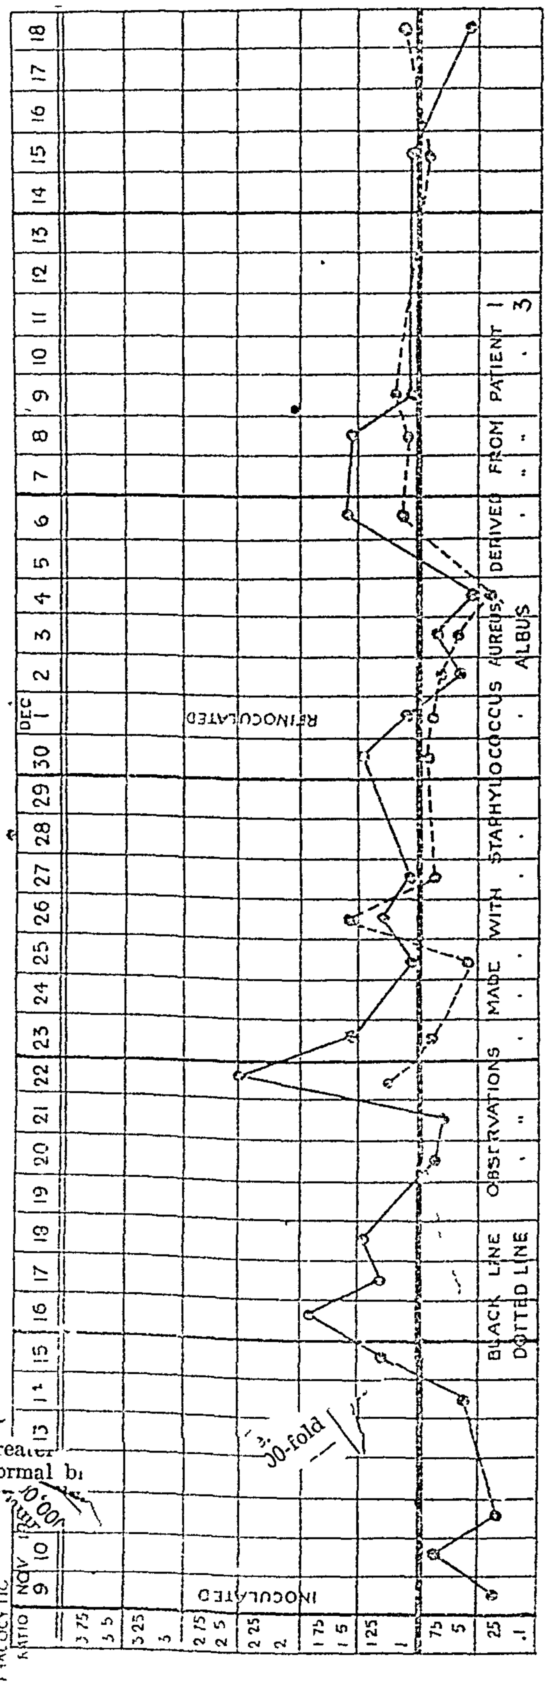
TABLE VI.—*Estimation of the Phagocytic Power of the Blood of the Patient in Case 3 anterior to Inoculation*

| — | Average number of staphylococci ingested by each polynuclear white blood corpuscle of the *control* blood. | Average number of staphylococci ingested by each polynuclear white blood corpuscle of the *patient's* blood. | Phagocytic ratio—i.e., the proportion in which the number of staphylococci ingested by each white blood corpuscle of *normal* blood stood to the number of staphylococci ingested by each white blood corpuscle of the *patient's* blood. |
|---|---|---|---|
| First estimation . | 16 6 | 6 5 | 1 . 0 39 |
| Second estimation .. | 21 0 | 8 0 | 1 . |

It will be seen that the phagocytic power of the pa[illegible] white blood corpuscles was between two and three times [illegible] than the phagocytic power of the white blood corpuscles of a normal blood.

*Particulars of the inoculations which were carried out and the clinical symptoms resulting from these.*—On Nov. 11th 1901, the patient was inoculated with one cubic centime[illegible] of the same staphylococcus vaccine which was employed [illegible] Case 2 (*supra*). The symptoms at the site of inoculation were comparatively trifling; the patient, however, felt a little out of sorts for two days. On Dec. 1st the patient was inoculated with 0 75 cubic centimetres of a staphylococcus vaccine prepared from agar cultures of the staphylococcus albus subcultured from himself. This quantum of vaccine represented the quantum of culture which developed on 1·5 square centimetres of agar surface. Marked local reaction was produced at the site of inoculation. The constitutional reaction was only very slight

*Particulars with regard to the effects produced upon the blood and upon the localised staphylococcus invasion.*—The effects exerted upon the condition of the neck and the concurrent changes in the blood are set forth below with some detail in parallel columns (Table VII.). The results of the blood examination are also presented in a synoptical manner in the form of a graphic curve (Curve 1).



CURVE 1 (relating to Patient 3).

The curve expresses the phagocytic ratio of the patient's blood (as estimated by Leishman's method), the phagocytic power of the control blood being everywhere taken as 1.

---

[13] This blood was derived from A. E. W.

herself for treatment on Sept. 28th, 1901. She stated that she had undergone a somewhat serious operation some 21 months previously. Since the date of that operation she had suffered from a succession of very painful deep-seated boils (a reference to her diary showed that the exact number of these had been 25). In addition she had constantly suffered from superficial boils and pimples which had made sitting uncomfortable. She complained also of a pustular discharge occurring intermittently from her nose and ears. The patient was for the moment free from deep-seated boils. A sample of blood was withdrawn for examination and the patient was inoculated with 0 75 cubic centimetre of staphylococcus vaccine.[9]

### DATA OF THE BLOOD EXAMINATIONS UNDERTAKEN BEFORE INOCULATION.

*Estimation of the inhibitory power exerted by the serum on the growth of staphylococcus.*—For the purposes of this estimation a 24 hour old broth cultivation of the staphylococcus aureus was diluted[10] with liquefied nutrient gelatin until a dilution of 1 in 1,000,000 had been arrived at. To a five-cubic-millimetre volume of this dilution was then added in each case an equal volume of (*a*) the patient's serum, (*b*) the patient's serum after this had been heated for 10 minutes to 60° C, (*c*) serum from a normal person, and (*d*) sterile nutrient broth. After these admixtures had been made the diluted culture was in each case drawn up into a capillary tube Three such tubes were being filled in with each variety of admixture. The following table shows the numbers of colonies[11] which developed:—

TABLE III.—*Showing the Number of Staphylococcus Colonies which Developed in Capillary Tubes filled in with Five Cubic Millimetres of the Diluted Gelatin Culture of Staphylococcus mixed with Five Cubic Millimetres of Serum or Broth as Particularised in Column 1 below*

| Admixtures which were made to the 1,000,000-fold dilution of staphylococcus culture. | Number of staphylococcus colonies which developed in each capillary tube | | | |
|---|---|---|---|---|
| | Tube 1. | Tube 2. | Tube 3. | Average of three tubes. |
| Patient's serum ... ... | 10 | 15 | 10 | 11·2 |
| Patient's serum previously heated to 60°C. for 10 minutes . . | 9 | 6 | 20 | 11·2 |
| Normal serum . . . | 11 | 13 | 11 | 11 1 |
| Sterile broth . . . . . | 18 | 9 | 16 | 14 0 |

Here manifestly the same results are obtained as in the case of the estimations undertaken before inoculation in connexion with Patient 1 (*vide supra*). In other words, no indication was obtained of anything in the nature of an inhibitory effect being exerted upon the staphylococcus by either the control blood or the patient's blood. We shall see in connexion with the next cases that the difference between the blood of patients suffering from staphylococcus invasions and the blood of normal persons is to be sought elsewhere.

*Particulars with regard to the subsequent inoculations and resulting clinical symptoms.*—The first inoculation was followed by very little in the way of either local or constitutional symptoms. Two further inoculations, in each case with one cubic centimetre of the same vaccine, were undertaken within the next three weeks. As in the case of the first inoculation the symptoms were very slight.

### DATA OF BLOOD EXAMINATIONS UNDERTAKEN A WEEK AFTER THE THIRD INOCULATION.

*Estimation of the agglutination power exerted by the blood upon the staphylococcus.*—The patient's blood now gives complete sedimentation in an eight-fold dilution The res[illegible] obtained with the control blood are, however, indef[illegible]

*Estimation of the bactericidal power.*—A 1,[illegible] dilution of a 24-hour old broth culture of the staphylococcus having been made, six measured volumes of this were transferred to the surface of agar. In the first of the six agar tubes (inoculated with 25 cubic millimetres of the diluted culture) nine colonies of staphylococcus made their appearance. In the second and third tubes (inoculated in each case with 15 cubic millimetres) the number of colonies which developed were in each case six. In the fourth tube (inoculated with 10 cubic millimetres) two colonies made their appearance. The fifth and sixth tubes (inoculated in each case with five cubic millimetres) remained sterile This gives an average of 3 07 colonies to each 10 cubic millimetres of the 1 in 1,000,000 dilution employed. Figuring this out we arrive at 307,000,000 as the number of staphylococci contained in a cubic centimetre of the undiluted culture.

The procedures connected with the enumeration of the culture having been completed, graduated dilutions of the original staphylococcus culture were made and were mixed in capillary tubes with the patient's serum and a normal serum respectively. In each case about five cubic millimetres of serum and diluted culture were employed. After an interval of 24 hours, during which the tubes were digested at 37° C, the capillary tubes were filled in[12] with sterile broth with a view of determining whether any bactericidal effect had been exerted. The results are subjoined:—

TABLE IV.—*Showing the Absence of Bactericidal Power in the Patient's Blood after these Inoculations.*

| Dilutions of the staphylococcus culture which were digested with the serum. | Results obtained on incubating the tubes after filling in with sterile broth. | |
|---|---|---|
| | Tubes containing the patient's serum, | Tubes containing normal serum. |
| 100-fold dilution. | Growth of staphylococcus. | Growth of staphylococcus. |
| 1000- „ „ | „ „ | „ „ |
| 10,000- „ „ | „ „ | „ „ |
| 100,000- „ „ | „ „ | „ „ |
| 1,000,000- „ „ | „ „ | „ „ |
| 10,000,000 „ „ | Tube remains sterile. | Tube accidentally contaminated. |

It will be manifest from these results set forth above that neither the normal serum nor the patient's serum exerted any bactericidal action upon the growth of the staphylococcus. Comparison with the result of the enumeration shows that five cubic millimetres of either serum failed to kill 1·5 staphylococci.

*Particulars with regard to the patient's condition after inoculation and estimations of the phagocytic power of the blood.*—The patient recorded that she felt herself better within 24 hours after the first inoculation. For the first time for months she could sit with ease. There was also a complete cessation of the purulent discharge from the nose

TABLE V.—*Showing the Phagocytic Power of Patient Two Months after Inoculation.*

| [illegible]ety of [illegible]lococcus [illegible]ich was employed | Average number of staphylococci ingested by each polynuclear white-blood corpuscle of *normal* blood. | Average number of staphylococci ingested by each polynuclear white blood corpuscle of the *patient's* blood. | Phagocytic ratio—i.e., the proportion in which the number of staphylococci ingested by *normal* blood stands to the number of staphylococci ingested by the polynuclear white-blood corpuscles of the *patient's* blood. |
|---|---|---|---|
| [illegible]aphylococcus aureus subcultured from Patient 1 ... .. | 25 7 | 10 6 | 1 : 0·41 |
| Staphylococcus albus subcultured from Patient 3 ... ... | 39 3 | 21·6 | 1 : 0 55 |

---

[9] This vaccine was a suspension in normal salt solution of a 24-hour-old culture of the staphylococcus aureus subcultured from Patient 1. The suspension was sterilised at 65° C. The quantum injected corresponded to the quantum of culture which was obtained from 0 75 square centimetre of agar surface.

[10] The dilutions were made with the diluting pipette figured by me in THE LANCET of June 1st, 1901, p 1532.

[11] The colonies were counted under the microscope by the technique described in THE LANCET of Dec. 1st, 1900, p. 1556.

[12] The technique that was employed was that described by me in THE LANCET of June 1st, 1901, p. 1532.

Three important points are clearly brought out by the observations made upon the patient. 1. The first of these points is that changes in the phagocytic power of the blood in the form of a negative phase of diminished phagocytic power succeeded by a positive phase of increased phagocytic power follow upon a staphylococcus inoculation. The negative and positive phases here obtained are plainly precisely analogous to the negative and positive phases of bactericidal power which I have shown to supervene upon an anti-typhoid inoculation. They are analogous also to the negative and positive phases which Ehrlich and Madsen have shown to supervene upon the inoculation of tetanus and diphtheria toxin respectively. 2. The second and equally important point which is brought out by the comparison of the clinical record with the results of the blood examination is that the negative and positive phases of phagocytic power stand in the very closest relation to the resisting power of the organism. So close and intimate does that association appear to be that it was, in this and the subsequent cases, always easy from the consideration of the local appearances to anticipate the results of the phagocytic estimation. 3. The general result of the blood examinations is in entire accordance with the theory of immunity put forward by Metchnikoff.

Case 4.—The patient, aged 21 years, a medical student, presented himself for treatment on Dec 20th, 1901. For the previous two months he had been suffering from boils chiefly on the nape of the neck, but also on the shoulder and forearm. Immediately anterior to the commencement of the boils the patient had suffered from an attack of influenza. The nape of the neck was seen to be the seat of a localised inflammatory process, the surface being occupied by three or four angry pimply boils, while the deeper tissues were considerably infiltrated and tumefied. The glands on both sides of the neck were somewhat swollen. On the cheek, in the neighbourhood of the nose, there were a certain number of very prominent spots of pustular acne. A cultivation made from one of the pustular pimples on the back of the neck yielded a pure cultivation of the staphylococcus aureus.

*Particulars of the inoculations undertaken, of the resulting symptoms and blood changes, and of the effect produced on the localised staphylococcus invasion.*—The course of treatment pursued and the effects which resulted from that treatment will perhaps be best gathered from a consideration of the subjoined tabular statement (Table VIII.).

The general deductions which can be drawn from a consideration of this case are precisely the same as those drawn from a consideration of Case 3. The absence of a negative phase in this particular case is no doubt to be imputed to the fact that very small doses of staphylococcus vaccine were employed. Interesting as bearing on the association between the changes in the phagocytic power of the blood and the changes in the condition of the patient are (1) the rapidity with which the therapeutic result was achieved taken in connexion with the rapid increase in the phagocytic power of the blood, and (2) the coincidence of the development of the pustular pimple on Jan. 3rd with the result of the blood examination instituted on that day. A further and very interesting feature which arrests attention in connexion with this case is the fact that the first inoculation was followed by considerable inflammatory swelling at the seat of infection. This phenomenon, which, as we shall see, made its appearance again in a very marked manner in connexion with Case 5, is a phenomenon which would seem to be precisely analogous to the local inflammatory reaction which is obtained after the injection of tubercle vaccine (Koch's tuberculin). It will be noticed in this connexion that no inflammatory reaction supervened upon the second inoculation, and generally that nothing of this kind has come under notice in connexion with inoculations undertaken upon patients whose tissues were presumably at the date of inoculation free, or comparatively free, from staphylococcus.

Case 5.—The patient, a private soldier, invalided home from Rawal Pindi for intractable sycosis, was first seen on Dec. 24th, 1901. The patient gave the following history. In 1893 he developed a little sore on the scalp which was followed by a general eruption all over the scalp and face. He was admitted to, and remained under

Table VIII.—Setting forth in Connexion with Case 4 (*a*) the Phagocytic Power of the Patient's Blood; (*b*) the Details of the Treatment Adopted; and (*c*) Particulars with regard to the Clinical Condition of the Patient.

| Date. | Variety of staphylococcus employed in the test. | Phagocytic ratio—i.e., the proportion which the number of staphylococci ingested by white blood corpuscles of *control* blood bore to number of staphylococci ingested by *patient's* blood. | Brief notes regarding the conditions of the localised staphylococcus invasion and the general condition of the patient. |
|---|---|---|---|
| 1901.<br>Dec. 20th | Staphylococcus albus from the patient in Case 3. | 1* . 0·78 | Condition as described in the text (*supra*). |

Inoculated with 0·3 cubic centimetre of a staphylococcus vaccine prepared from agar cultures of staphylococcus albus subcultured from the patient in Case 3. The quantum inoculated corresponds to the quantum of culture which developed on 0 6 square centimetre of agar surface.

| Date. | Variety of staphylococcus employed in the test. | Phagocytic ratio. | Brief notes. |
|---|---|---|---|
| Dec. 21st | Staphylococcus albus from the patient in Case 3<br>Staphylococcus aureus derived from the patient himself. | 1 . 2<br>1 : 3 8 | There has been very little local reaction at the site of inoculation and only slight constitutional disturbance. Considerable swelling has, however, developed in the neck. Signs of improvement in the fact that the superficial boils have lost their angry look. There is considerable polynuclear leucocytosis. |
| ,, 24th | Staphylococcus aureus from the patient himself. | 1† : 6·48 | The patient reports that there has been very considerable inflammatory swelling of the neck and of the lymphatic glands. The swelling has now almost subsided. The boils have entirely disappeared and the leucocytosis has passed off. |

Inoculated with 0 5 cubic centimetre of a vaccine prepared from agar culture of the patient's own staphylococcus aureus. The quantum inoculated corresponds to the quantum of culture which developed in 0 5 square centimetre of agar surface.

| Date. | Variety of staphylococcus employed in the test. | Phagocytic ratio. | Brief notes. |
|---|---|---|---|
| Dec. 27th | Staphylococcus aureus from the patient himself. | 1 · 2 | No constitutional reaction. Congestion and tenderness for 48 hours at the seat of inoculation. No further swelling of the glands or inflammatory reaction in the neck. The patient is quite free from boils and acne. There is some leucocytosis. |
| 1902.<br>Jan. 3rd | ,, | 1 : 1 | One small inflamed pimple has developed on the neck. The patient otherwise is quite well and there is no leucocytosis. |
| ,, 10th | Staphylococcus albus from the patient in Case 3. | 1‡ : 0 95 | The neck is perfectly well. No trace remains of boils, acne, or swollen glands. |
| ,, 17th | — | — | The patient, who is leaving the neighbourhood, reports himself as being perfectly well. A similar report was received on March 15th, 1902. |

---

* The control blood employed in this and the five following estimations was derived from A. E W.

† This result may conceivably have been due to some error of technique or to some incidental lowering of the phagocytic power of the control blood. Vide in this connexion the remarks appended to Table IX. and Curve 2.

‡ The control blood here employed was derived from W. B. L. The phagocytic power of this blood has invariably been found to be higher than that of A. E. W.'s blood.

TABLE VII.—SETTING FORTH IN CONNEXION WITH CASE 3 (*a*) THE PHAGOCYTIC POWER OF THE PATIENT'S BLOOD; (*b*) THE DETAILS OF THE TREATMENT ADOPTED; AND (*c*) PARTICULARS WITH REGARD TO THE PATIENT'S CLINICAL CONDITION.

| Date | Variety of staphylococcus employed in testing the blood | Phagocytic ratio—i.e., the proportion in which the number of staphylococci ingested by each polynuclear leucocyte of the *control* blood stood to the number of staphylococci ingested by each of the *patient's* polynuclear leucocytes | Brief notes regarding the localised staphylococcus invasion and the general condition of the patient |

* In this and all subsequent estimations unless where otherwise specified the control blood employed was derived from W. B. L.

† The control blood used in this estimation was derived from F. N. W.

‡ Three normal bloods, those of W. B. L., F. N. W., and A. A., were here employed as controls. The results obtained in the case of these bloods were in the closest agreement.

§ The blood here employed was derived from A. E. W. It is a blood which possesses a low phagocytic power.

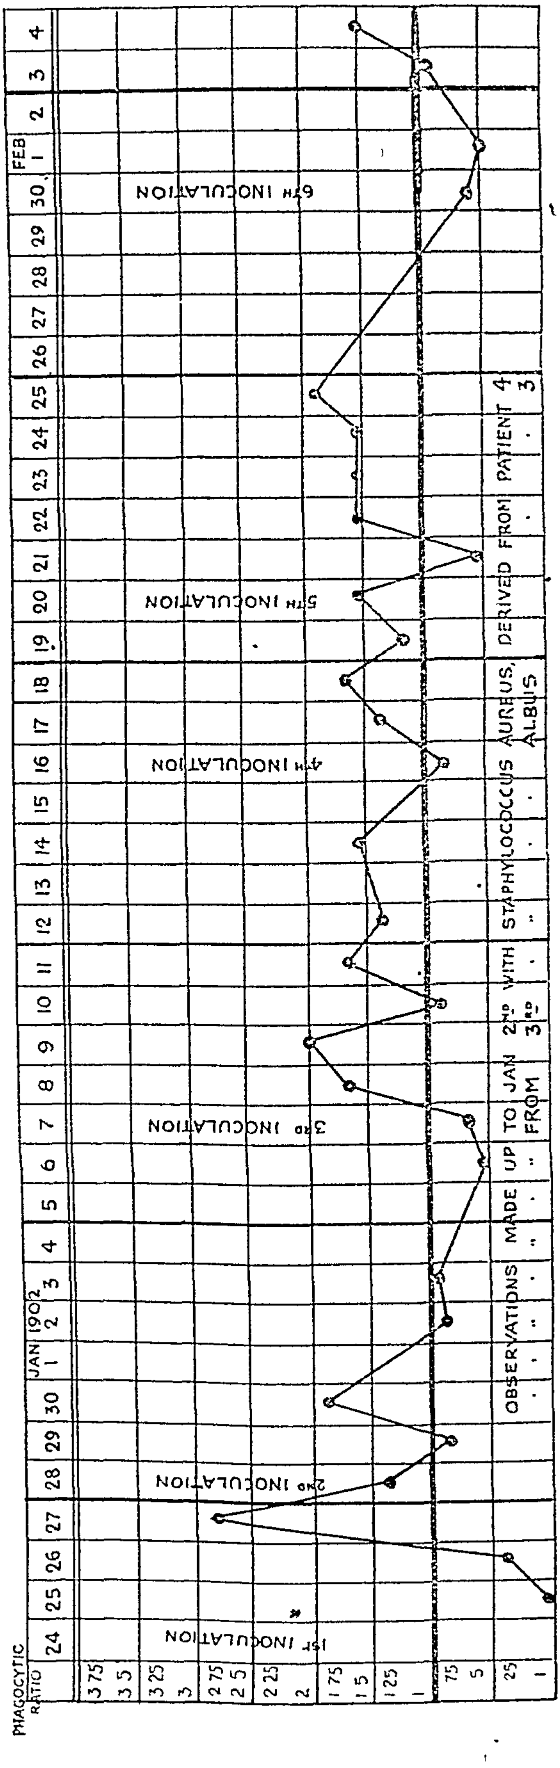
treatment in, the Camberwell Infirmary for six weeks and was then discharged "cured." When he enlisted in 1897 he had, however, still a minute patch of eruption in front of his left ear. After serving for six months he was admitted to hospital for a deep-seated boil in the left parotid region which developed in connexion with the uncured patch of eruption just spoken of. He remained under treatment for about a fortnight. In the same year he proceeded to India and remained well for a time. In 1899 he attended hospital for three months for sycosis and eczema of the face. He relapsed again in 1900 and spent nine weeks in hospital, afterwards attending as an out-patient. He was readmitted in 1901 and was invalided home after spending six or seven months in hospital under energetic treatment. The patient, whose face and head were entirely swathed in dressings, was suffering from a very aggravated form of sycosis complicated by eczema. The whole area of the chin, the cheeks, and the under surface of the jaw was extensively infiltrated and was thickly covered in places with moist scabs. A number of pustular points were interspersed between the prominences corresponding to the inflamed hair follicles. The bony contours of the jaw were almost obliterated by dense masses of infiltrated tissue. The scalp and in particular that portion of it overlying the squamous portion of the left temporal bone was the seat of a scabby sero-pustular affection corresponding to that described under the name of acne varioliformis. The eyebrows and the margins of the eyelids were the seat of a chronic pustular inflammation.

*Data of the microscopical and bacteriological examinations which were instituted.*—A careful examination of the hairs of the beard showed that these were not invaded by any parasitic mycelium. Cultivations made from the pustular points on the face yielded pure cultivations of the staphylococcus aureus.

*Details of the inoculations undertaken and of the effects of these upon the blood and the localised staphylococcus invasion.*—The particulars of the inoculation undertaken and of the effects produced on the blood and on the area invaded by the staphylococcus are subjoined with some detail in tabular form (Table IX.). The results of the blood examinations are given also in the form of a curve (Curve 2).

Attention may be drawn to the following points in connexion with the table and the curve. 1. The high expression obtained for the phagocytic power of the patient's blood in the case of the first estimation recorded in the table would seem to have been due either to an under estimation of the phagocytic power of the control blood due to an error in the technique or to some incidental lowering of the phagocytic power of that blood. There are thus in this case no trustworthy data relating to the phagocytic power of the patient's blood before inoculation. 2 It will be observed that, as in the cases already considered, an increase of phagocytic power was registered after each inoculation. 3 In the case of the first and second and again in the case of the fifth and sixth inoculations undertaken respectively with a double and a treble dose of the vaccine the positive phase was preceded by a negative phase of diminished phagocytic power. 4 The clinical record shows that a condition of diminished phagocytic power, whether produced by inoculation or occurring spontaneously, was in each case associated with aggravation of the local affection. 5. The clinical record further shows that a condition of increased phagocytic power was invariably associated with an inflammatory (phagocytic) reaction in the area invaded by the staphylococcus and with a subsequent improvement in the form of a restriction of the invaded area 6. It would appear from the consideration of the present case, taken in association with the cases already considered, that where the scale is turned against the invading staphylococci, it is turned not by a change produced in the blood-fluids, but by a succession of immunising impulses, each such impulse expressing itself in an inflammatory (phagocytic) reaction localised in the invaded tissues.

The results of the continuation of the treatment up to March 15th have confirmed the premonitions of a proneness to relapse which may be gathered from the previous history as well as from the results of the blood examinations and clinical data incorporated in the table and curve. In each case, after an improvement extending over three or four days subsequently to inoculation, symptoms of a certain amount of relapse have manifested themselves both in the condition of the local infection and in the results of the blood examinations. At present, after 10 further staphylococcus inoculations which have been timed, and varied with respect to dose, in accordance with the results of the daily blood examinations, the patient's condition is still that of a chronic staphylococcus invasion associated in places with a certain amount of scabbing and infiltration. There would thus appear to be a very definite limit to the defensive reaction of the organism, a limit which comes into consideration also in the case of other inoculations.



CURVE 2 (relating to Patient 5).

The curve expresses the phagocytic ratio of the patient's blood, the phagocytic power of the control blood being everywhere taken as 1.

* The control blood employed in these estimations was derived from A. E. W.

† The control blood employed in these estimations was derived from W. B. L. It is a blood which possesses a high phagocytic power.

Vide in connexion with results of phagocytic estimation on Dec. 24th, 1901, note † appended to Table VIII.

### CONCLUDING REMARKS.

*Possibility of a still wider extension of the treatment of localised inflammatory conditions by inoculation.*—We may inquire, in conclusion, into the prospects of successfully exploiting bacterial vaccines in the treatment of localised inflammatory processes produced by pathogenic micro-organisms other than the staphylococcus. Much that is of value can be learned upon this subject by a careful consideration of Koch's tuberculin inoculations and by a comparison of these with the inoculations of staphylococcus vaccine with which we have been dealing above. In each case a bacterial vaccine is, for therapeutic purposes, inoculated into patients already the subject of a corresponding infection. In each case, as the result of the inoculation, an acute inflammatory reaction is set up at the seat of infection. In each case, again as a result of the inflammatory reaction in question, the nidus in which the bacteria are lodged is broken up.

At this point an all-important difference emerges. In the case where the localised inflammation process is due to a staphylococcus infection the breaking up of the nidus has involved, so far as has hitherto appeared, a destruction of the bacteria which have been fluttered. In the case of a tubercle infection the destruction of the nidus has, on the other hand, been shown to be compatible with the continued survival of the tubercle bacilli. Judging by the event recorded in connexion with many tuberculin inoculations, the tubercle bacilli when set free by the inflammatory reaction would appear to have been merely carried away by the white blood corpuscles or lymph current to give origin to new localised foci of infection, or, in exceptional cases, to a generalised form of tuberculosis.

When we consider what may be the reason of this difference in the event which has followed the inoculation of these two different bacterial vaccines we realise that it must be attributed primarily to the fact that the tubercle bacillus possesses, as compared with the staphylococcus, an infinitely greater capacity for maintaining its vitality in the interior of the organism.

A further reason for the difference in event we may perhaps find in the fact that while it was possible in the case of the staphylococcus inoculations described above to graduate the doses and time the injections in accordance with the data supplied by the measurement of the patient's resistance (as judged by his phagocytic reaction and by the condition of the invaded tissues) it was impracticable to do this—although it was infinitely more important to do so—in the case of Koch's inoculations of tubercle vaccine. We are thus by a comparison of the inoculations undertaken with staphylococcus vaccine with those undertaken with Koch's tuberculin again led back to the cardinal principle that we must, in connexion with every therapeutic application of a bacterial vaccine, consider, on the one hand, the capacity of resistance with which the particular species of invading micro-organism is endowed, and, on the other hand, the capacity of resistance possessed by the particular patient at the time of inoculation.

The ideal to be kept in view must everywhere be so to graduate the doses of the bacterial vaccine and so to time the injections as to leave to the infected patient in any negative phase which may supervene after inoculation a sufficient margin of resistance to safeguard him against any generalisation of his infection.

In connexion with the possibility of a wider extension of the principle of therapeutic inoculation we may with advantage keep in view (1) the consideration that patients who have been suffering from long-continued localised inflammation processes would seem, so far as can be judged from clinical experience, to have acquired a defensive power such as suffices to ward off the more generalised forms of their particular infections; and (2) the consideration that where bacterial invasions manifest themselves only under the form of "surface-invasions" the conditions in the interior of the organism must be assumed to be *ab initio* hostile to the growth of the invading micro-organisms.

These considerations would seem to point to the desirability of testing the effect of therapeutic inoculations of sterilised streptococcus cultures in the case of patients who are the subject of indolent and relapsing forms of erysipelas. In applying an inoculation treatment to the forms of erysipelas referred to it would of course be necessary to keep in view the fact that the streptococcus possesses, as compared with the staphylococcus, a much greater capacity for generalising itself in the organism.

The above considerations would also seem to point to the desirability of determining whether any therapeutic advantage could be derived from the inoculation of the appropriate bacterial vaccines into patients suffering from chronic "surface-invasions." There would be opportunity of applying such inoculations in connexion with the treatment of bronchitis, ozæna, gleet, leucorrhœa, and those forms of the bacteriuria[14] which depend upon a bacterial invasion of the mucous membranes of the genito-urinary tract. It would of course be necessary in each case, after determining the particular species of invading micro-organism which was giving rise to trouble, to consider (1) the question of technique in connexion with the preparation of the vaccines; (2) the question as to whether the particular invading micro-organism possessed any power of generalising itself in the system; and (3) the question of the resisting and reacting power of the particular patient. In connexion with the estimation of these last, the methods of estimating the bactericidal power of the blood which have been described by myself[15] and the method of estimating the phagocytic power of the blood which has been described by Major Leishman[16] are, I think, capable of rendering services.

In bringing this communication to a close I desire to express my acknowledgements to Captain G. McIver C. Smith, I.M.S., for helpful collaboration in connexion with the study of Case 1. To my colleague, Major Leishman, R.A.M.C., I am indebted for manifold and unwearying assistance and valuable criticism throughout the whole course of this investigation.

Netley.

# THE SURGERY OF NON-MALIGNANT GASTRIC ULCER AND PERFORATION.

BY C. B. KEETLEY, F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON HOSPITAL.

THE following notes are rather detailed. Experience of detail is exactly what I have felt the need of when commencing non-malignant gastric surgery. Some of the cases are of exceptional interest, otherwise they would not have come under the surgeon's notice, as they are derived from sources most of which had not at the time realised how much surgery can do for commonplace cases of obstinate gastric trouble. The cases here reported are not selected, but with those of "severe gastric hæmorrhage" reported in THE LANCET in June last year,[1] with three cases of ulceration of the stomach and œsophagus from hydrochloric acid poisoning, which form the subject of a paper read before the Royal Medical and Chirurgical Society,[2] and with a case of tetany of gastric origin briefly noticed in THE LANCET,[3] they form a complete though small series of 22 non-malignant gastric cases. Most were operated on—a few were not. Remarks are appended to some of the cases individually. A few general observations may be divided into (1) those on perforation cases; and (2) those in which evidence of perforation was wanting or very inconclusive.

### PERFORATION.

Precision or certainty in diagnosis is, in most cases of gastric perforation, not possible, even to experienced persons. *But it is not necessary.* The medical man who waits for a case in which the peritoneal cavity is obviously distended with gas, obliterating the liver dulness, while the vomit contains blood, while excruciating pain and tenderness are localised in the stomach region, and there is a known previous history of gastric ulcer, with hyperacidity, hæmatemesis, epigastric tenderness, pain after meals, and dilatation

---

[14] Experiments in connexion with the application of inoculation in connexion with the last of these disorders are now in progress.

CASE 6.—The patient, a man, about 40 years of age, was first seen on Feb 18th, 1902. A fortnight previously he began to suffer from an acute inflammation of the hair follicles associated with a considerable amount of serous discharge and itching. The inflammatory process now occupies the whole area of the beard and hairy portion of the cheeks, and it has spread backwards and has affected the nape of the neck and the lower portion of the back of the scalp. The whole of the affected area is thickly occupied by discrete, for the most part dry, scabs conforming to the type of acne varioliformis Associated with these there is in places a certain amount of serous discharge. The scalp generally is extremely scurfy. Cultivations made from the surfaces exposed by removal of the scabs yielded a pure cultivation of staphylococcus aureus. The particulars of the treatment and details as to the result obtained are subjoined in Table X.

TABLE X.—SETTING FORTH IN CONNEXION WITH CASE 6 (*a*) THE PHAGOCYTIC POWER OF THE PATIENT'S BLOOD; (*b*) THE DETAILS OF THE TREATMENT ADOPTED; AND (*c*) PARTICULARS WITH REGARD TO THE PATIENT'S CLINICAL CONDITION.

* The control blood employed was that of W. B L

† The control blood employed was that of W. G. L.

It will be noted on study of the above table that there was a marked increase in the phagocytic power of the patient's blood on the day succeeding the inoculation. On this and the next two days the clinical condition improved in an astonishing manner. The phenomena which succeeded upon reinoculation are of less conspicuous interest. It will be seen that after the second inoculation, which was resorted to with a view to checking the falling away of the phagocytic power which manifested itself on the third day after the first inoculation, a pronounced negative phase of diminished phagocytic power came under observation. This negative phase, presumably owing to the fact that the invading bacteria had already been disposed of, was unaccompanied by anything in the nature of an aggravation of the patient's symptoms At the date of the patient's discharge the negative phase was apparently giving place to a positive phase of increased phagocytic power.

### CONSIDERATIONS IN CONNEXION WITH THE POSSIBLE PROPHYLACTIC AND THERAPEUTIC APPLICATIONS OF ANTI-STAPHYLOCOCCUS VACCINE.

Having in the foregoing considered the results obtained by the inoculation of staphylococcus vaccine into patients affected with furunculosis, sycosis, and acne, we may naturally be led on to inquire whether there are any other forms of staphylococcus invasion in connexion with which these inoculations *might perhaps find a useful application.*

*Possible prophylactic applications.*—Dealing first with the question of a possible application of these vaccines in connexion with *the prophylaxis of septic invasion*, it would seem that advantage might possibly be derived from their application in connexion with compound fractures and further in connexion with operative procedures, such as those associated with the upper jaw and air passages, where it is impossible to secure the asepticity of the wound. It is, perhaps, venturesome to suggest that there might also be other cases where the surgeon might be willing in his operative procedures to avail himself of the increased resistance to staphylococcus invasion which would, it can hardly be doubted, be obtained by a prophylactic inoculation of staphylococcus vaccine. I would urge in defence of this suggestion that the adoption of measures designed to increase the resistance of the organism to septic invasion would seem to be only a legitimate development of the accepted practice of relying upon the protective agencies of the organism instead of upon the application of antiseptics for the destruction *of such septic bacteria as may upon* occasion in spite of aseptic precautions obtain access to wounds

*Apart from* actual surgical procedures it would seem possible that prophylactic inoculation of staphylococcus vaccine might find a scientifically interesting and conceivably a practically useful application in connexion with anti-small-pox vaccination. In view of the apparently septic character of the inflammation which is frequently associated with vaccination wounds and the fact that staphylococci are constantly present in vaccine lymph even in glycerinised lymph I take it that it would be desirable to determine how far the staphylococcus is responsible for the *symptoms which have done so much to discredit vaccination* in the popular mind The information which is required could probably be obtained by noting the effects produced by the inoculation of one and the same variety of vaccine lymph into persons or animals immunised against the staphylococcus and into persons or animals not so protected I shall be glad to place a supply of staphylococcus vaccine at the disposal of any medical man possessing facilities for undertaking such inquiry.

Comparatively little remains to be added to what has already come *under consideration in connexion with the* therapeutic employment of staphylococcus vaccine. It is possible that the vaccine might find a useful application, not only in connexion with the treatment of furunculosis, acne, and sycosis, but also in connexion with the treatment of Veldt sores, old ulcers, sinuses, and septic vaccination wounds.

other similar cases in the practice of surgeons who suture the mucous edges together. When suppuration threatens beneath the skin we can often prevent it by removing sutures, but an analogous practice is impossible in the stomach. This Case 8 is interesting as having been apparently one of capillary hæmorrhage, as no ulceration was discovered even post mortem. The patient in one case had in the course of five years been twice "cured" by rest in bed and a milk diet, the cure once lasting for a whole year. In connexion with this case a few words may be said about Murphy's button.

*Murphy's button.*—Gastro-enterostomy by this means is, as von Miculicz and others point out, singularly free from the risk of the "circulus vitiosus" or persistent regurgitation into the wrong arm of the jejunal loop and so back into the stomach and round and round. Murphy's button seems to me to have other advantages. It keeps together broad surfaces of the two parts to be united. It keeps them uniformly together if carefully applied. It runs no risk of a weak point where one suture has not been put in so carefully as its neighbours or where one suture is exposed to undue strain. It is an obvious protection against recurrent hæmorrhage, a real danger in gastric operations. Further, it protects the parts of both stomach and intestine beyond its circumference from septic infection, just as a ligature round a finger would keep snake venom out of the general circulation. The speed with which it can be applied is a secondary consideration; indeed, I suspect that it tends to discredit the button, because it leads to its being selected for specially bad cases, and also leads to its being put in hurriedly. No hurry should be used; on the contrary, great care and precision are indicated in (1) adjusting the cut edges of the inner serous aperture to the central cylinder of the button, turning in all mucous membrane; (2) in putting in and tying the two or three silk sutures which finally reduce the size of the aperture; and (3) in bringing the two parts of the button correctly together and gradually closing them until the two serous surfaces are in absolutely close contact *all round* the button and slightly compressed together.

The chief drawback to the use of the button is its liability in gastric cases to fall back into the stomach, or even, it is said, into the wrong part of the jejunal loop. The former accident has happened to me twice, and once also the button remained for several weeks fixed in the gastro-enterostomy opening (in a case of hydrochloric acid poisoning not in this series). In the latter case I had not pressed the halves of the button tightly enough together. In these cases the button was easily localised with the x rays and as easily removed. Even before the advent of antiseptics and long before surgeons were as accustomed as they now are to gastric surgery gastrotomy for the removal of a foreign body was a very safe operation.

It has recently been said that "it is difficult to imagine anything more likely to irritate the ulcer than a Murphy's button being continually churned against it." The question is not one of imagination at all but of experience, which shows that the use of the button permits the ulcer to heal rapidly. And, why not? Murphy's button is not a solid chunk of cast iron, rough and angular, but is a hollow, light, rounded and polished ring of thin sheet metal. With regard to "churning," the stomach is a muscular organ, and when, thanks to a successful gastro-enterostomy, it has acquired the power of emptying itself with ease it grasps its contents and moves them on in an orderly and quiet manner. I am reminded of an objection urged by the late Mr. Adams of Bungay against lithotrity—that it "turned a man's bladder into a gravel pit."

The knob of each half of the button can be introduced through a surprisingly small cut in either the stomach or the intestine, a cut shorter than the diameter of the knob. An assistant should hold two points of the cut edge with catch forceps; the surgeon should then seize another point with dissecting forceps. The opening thus becomes triangular and through it the button knob, gripped by the edge with a pair of catch forceps, should be gently rotated and persuaded to pass in. The forceps which grips the button edge should then be handed to the assistant, while the surgeon puts in a couple of fine silk sutures through the "sero-muscularis" to tighten up. The substitution of these interrupted sutures for a running suture all round the button is, so far as I know, due to Carle and Fantino. Each button should be examined, tested, and found in good order as regards the spring and catches. But for this precaution I should on one occasion have used a defective button. In searching for a retained button with the x rays it is necessary to turn such patients as are not very thin on their faces. The button then falls forward close to the anterior abdominal wall, against which the screen should be placed.

*A Table by which this Small Series of 22 Cases may be Analysed into 11 Distinct Varieties.*

| Variety and No. of case. | — | Operated on or not. | Recovered or died. | — |
|---|---|---|---|---|
| I. 1 | Perforation operated on as such (Cases 1, 2, 3, and 4). | Operation. | Recovered. | Case 1 was a "spontaneous" rupture of the stomach. |
| 2 | | ,, | ,, | Each operated on from 24 to 30 hours after the perforation. |
| 3 | | ,, | ,, | |
| 4 | | ,, | ,, | |
| II. 5 | Perforations operated on as cases of general septic peritonitis two cases, each at least four days after perforation (Cases 5 and 6). | ,, | Died. | — |
| 6 | | ,, | ,, | Death partly due to a second perforation after operation on the first. |
| III. 7 | Perforations not operated on (Cases 7 and 8). | No operation. | ,, | — |
| 8 | | ,, | ,, | |
| IV. 9 | First seen as subphrenic abscess (Cases 9 and 10). | Operation. | Recovered. | — |
| 10 | | No operation. | ,, | Still imperfectly recovered. |
| V. 11 | Revolver shot wound of the stomach and the liver with extrusion of omentum (Case 11). | Operation. | Died. | — |
| VI. 12 | Persistent capillary (?) hæmatemesis (Case 12). | ,, | ,, | — |
| VII. 13 | Acute severe hæmorrhage (Case 13). | ,, | Recovered. | — |
| VIII. 14 | Old history of ulcer and very severe hæmorrhage, gastric dilatation. Tetany; death before there was time to summon a surgeon (Case 14). | No operation. | Died. | — |
| IX. 15 | Ulcer several times relapsed after dietetic treatment in hospital (Case 15). | Operation. | Recovered. | — |
| X. 16 | The three cases of hydrochloric acid poisoning. | Operation. | Recovered. | — |
| 17 | | ,, | ,, | Much better for gastrostomy, but died nearly two months afterwards from progressive ulceration of the œsophagus and direct infection of the lung. |
| 18 | | No operation. | Died. | — |
| XI. 19 | The four severe hæmorrhage cases.* | Operation | Recovered. | |
| 20 | | ,, | ,, | — |
| 21 | | No operation. | Died. | — |
| 22 | | ,, | ,, | — |

* See THE LANCET, June 8th, 1901, p. 1597.

Thus of the 15 cases operated on 11 patients recovered and four died. Of the seven cases not operated on, six patients died, and the sole survivor is still more or less an invalid. Of the four fatal operated cases, two were of general septic peritonitis operated on four days after perforation; one was that of the infant shot through the liver and of the stomach, may expect to become responsible for such melancholy cases as Case 3 and Case 4 detailed hereafter.

Quite a small number of the above symptoms should suffice to excite grave suspicions if they come on suddenly, and they need not be at all well-marked. If, then, the physician or practitioner cannot make up his mind as to what has happened, that uncertainty is not an indication for waiting but for immediately calling in the surgeon. The surgeon then shares the responsibility, and a grave and difficult one it often must be, especially if the case is far away in the country and "now or never" is the time for decision. The cases here recorded tend to show that it is best to settle the question of diagnosis by an immediate exploratory operation Compare, for example, the results in Cases 1, 2, 3, and 4 with the results in Cases 5 and 6.

Sudden and severe abdominal pain with faintness and with or without vomiting are ominous symptoms in either women or men, especially if there is anæmia and a history suggestive of chronic indigestion. Note that in Case 2 there was absolutely no abdominal tenderness, no vomiting, and little pain or distension. Yet there was a gastric perforation, while the pus and lymph in the pelvis and elsewhere showed that the case was fully started on the course which led the patients in Cases 5, 6, and 8 to the grave and the subject of Case 9 into a condition of chronic invalidism.

With due care, gentleness, and experience an exploratory laparotomy becomes a simple and safe affair. If a large hole be made in the abdomen, the arm thrust in half way up to the elbow, and the hand carried round and round all over the viscera from the diaphragm to Douglas's pouch, a patient may be made alarmingly ill by it, especially if strict asepsis is not secured. But any procedure so rough as this is very rarely, if ever, necessary. Almost always a shrewd guess at localisation can be made before incision, and generally the pylorus or the cæcum, or whatever has to be dealt with, can easily be drawn outside and the neighbourhood explored with two or three fingers.

One of the first rules in all doubtful cases is, "Do not feed by the mouth." And do not be in a hurry to leave off rectal feeding. In Case 8 the patient who refused to be operated on was at first in a favourable position because so many hours had elapsed between the time of the perforation and of the last meal, but three or four days afterwards, when she had ceased to be under my care, oral feeding was recommenced. This may have contributed to bring about the fatal termination.

After operation, especially if Murphy's button be used and the patient be very low and not vomiting, liquid food may be allowed by the mouth very early, or even immediately. As vomiting would prevent this, very little general anæsthetic should be given, and that only during the really painful part of the operation. If ether or chloroform is being given the mask or other appliance should be taken off the mouth as soon as the stomach is brought out and not reapplied till the need for it is apparent. The surgeon ought to be allowed to *see* that the anæsthetic is not being given. Even if the patient soon vomits a little no great inconvenience is caused to the operator who has a reasonably good assistant. In the value of ether or any other drug "as a stimulant" during operation I do not myself believe. Let the patient be kept warm, the blood-vessels full, and the breathing free, and no stimulant will be needed If these are neglected no stimulant is any good. After operation for perforation it is better to give only hot water, in half-ounce doses hourly by the mouth for several days and peptonised milk enemata, four ounces every four hours, with occasionally a 10- or 20-ounce enema of hot water to relieve the thirst or to strengthen the pulse. Plasmon is useful (one drachm to four ounces of milk). Opium is a great reliever of pain, but even as an anodyne it is a good deal less effective than correct surgical treatment, which it often fatally obstructs and hampers. I rarely give it. Large doses are bad and small ones are generally either ineffective or not necessary. Both large and small doses are apt to lull into a false feeling of security. This fault was conspicuous in several of these cases.

The precise nature of the illness of the patient in Case 7 was never determined. There may have been even at first hæmorrhage, but, in spite of her sex, I think that it was more probably perforation of a duodenal ulcer, localised peritonitis, improvement for 10 days, and finally severe hæmorrhage due to erosion or sloughing of some considerable vessel and death. It shows how insufficient even strict rectal feeding and rest may prove even in a most favourable case. Perhaps a timely gastro-enterostomy would have saved this patient.

One of the dangers of delay and of not applying surgery until a case is in a depressed and bad condition is that operation is then liable to be hurried and essentials may be thus overlooked. The pelvis was not explored and cleansed in Case 5. The pelvic peritoneum should always be examined, and, if necessary, cleansed, even when the peritonitis or perforation is in the upper half of the abdomen. The converse is not absolutely true. I mean it is not always desirable to examine the perihepatic peritoneal spaces when peritonitis has begun in the pelvis or about the appendix, but some lives are lost even through this not being done. Case 6 was in too desperate a condition for much surgery, and the fact that the prime focus of mischief was behind the stomach, through the foramen of Winslow, was not discovered till after death. I think it would have been quickly found at the operation had the surgeon been called in before the suppurative peritonitis was universal.[4]

Just as several of these cases show clearly the evil of delay and of waiting for death and a diagnosis to arrive together, sometimes treading close on the heels of surgery applied too late, so clearly is great credit due to the promptitude, knowledge, and acumen of Dr. A. H. W. Clemow, Dr. Otto Grunbaum, Dr. D. Fairweather, and Dr. H. Lawson, to which the patients in Cases 1, 2, 3, and 4 owe their lives.

As in Case 1 the rupture did not take place through an ulcer, but only in, or close to, a cicatrix, and as it was not the result of external violence I think it comes under the classification of "spontaneous rupture."

Although in Case 2 the lower limit of liver dulness was only pushed up about two centimetres above the edge of the rib cartilages, and even that was caused by air in the greatly distended transverse colon rather than by the small quantity of gas free in the peritoneal cavity, Dr. Grünbaum rightly attached great weight to the symptom. Diagnosis in this case was further complicated by the nervous and hysterical state of the patient. She had no abdominal tenderness.

In Case 11, that of the infant who was shot through the liver and stomach and who died on the eighth day, there are several obvious points which recall the case of President McKinley. This unfortunate child, aged 14 months, was handicapped by (1) marked rickets; (2) whooping-cough; and (3) a burn to the bone on the right heel. I regret now not having excised the whole of the bruised and extruded omentum. It was, however, carefully cleaned, not only by us, but by Mr. H. W. Chambers of Goldhawk-road who sent the patient into hospital so promptly. The oblique incision parallel to the edge of the rib cartilages proved admirable for exposing the whole stomach and even the spleen.

The patient in Case 5 had parotitis after operation for perforation performed on the fifth day. This case was also remarkable on account of the second perforation, which I am certain followed the laparotomy performed for the first perforation and polluted the sutures which lay near it, thus destroying what little chance of life this case possessed.

*Sub-diaphragmatic abscess.*—Cases 9 and 10 illustrate the long and dangerous period of chronic invalidism which may ensue even if a case of gastric perforation which is not operated on escapes the immediate danger to life.

### NON-PERFORATIVE CASES.

In THE LANCET of June 8th, 1901 (p. 1597), I have published four of these cases in which severe hæmorrhage occurred Case 12 in this series ought really to have been published with those four, but it was forgotten, probably because it was not operated on. With regard to Case 8 the result may be traced, I think, to several causes. 1. To the overloading of the whole colon with masses of fæces, which overloading was due partly to the prolonged previous use of opium and partly to insufficient preparation of the patient before operation. It is quite possible that the persistent vomiting which had lasted for five weeks daily was itself partly caused by the opium and the constipation. 2. To the close continuous glover's suture with which I sutured the edges of mucous membrane together. Abscess between the layers of the stomach wall occurred and the suture in question must have tended to prevent the discharge of the pus into the gastro-intestinal canal. I know of two following passage. Captain Yule says, after describing Maphoon :—

---

[4] Kingston Barton writes "If there is delay the symptoms become more general and less clear and the surgeon himself fails to recognise the necessity of immediate operation. Several of my cases sent to hospital were lost for this reason." (Records from General Practice, vol. i., p. 7.)

"Her husband and her two boys accompanied her. The elder, about four or five years old, had nothing abnormal about him. The youngest, who was 14 months old and still at the breast, was evidently taking after his mother. There was little hair on the head, but the child's ear was full of long silky floss, and it could boast a moustache and beard of pale silky down that would have cheered the heart of many a cornet"

Dr. Cholmeley has had the portrait of Maphoon and her infant son reproduced and has sent it to me together with the above quotation. Owing to his courtesy I am able to exhibit portraits of the man at two different ages and thus to add considerably to the interest of this communication.

Weymouth-street, W.

# A CASE OF APPENDICITIS IN WHICH THE APPENDIX WAS LODGED IN, AND ADHERENT TO, THE FEMORAL CANAL.

By JOHN HENRY GALTON, M.D. Lond.,

SURGEON TO THE NORWOOD COTTAGE HOSPITAL, &C.

The patient was a woman, aged 32 years whose previous history was to the effect that in January, 1900, she had an attack of appendicitis from which she recovered. I saw her on Oct 11th, 1901, when she had been suffering for some days from indigestion and abdominal pains, and was at the time complaining of pain in the right lower abdomen, with tenderness over McBurney's point. Her temperature was 98° F. and her pulse-rate was 90 ; there was no abdominal tension at any part. She was given an ounce of castor oil with 15 minims of tincture of opium and 20 minims of spirits of chloroform. On Oct. 12th at 11 A.M. her temperature was 107° and her pulse-rate 118 ; in the right iliac region there was great pain together with dulness and muscular tension, but there was no general abdominal tension. She was given 10 grains of citrate of potassium and eight minims of tincture of belladonna every four hours. At 7.30 P.M. her temperature was 101·4° and her pulse 100. On the forenoon of the 13th her temperature was 102°, her pulse 100, and her respiration 30 ; at 6 P.M. her temperature was 102° and her pulse 100. On the 14th her temperature was 101·6°, her pulse 87, and her respiration 26 At 9 A.M. she had an enema which acted well, producing a solid motion. The swelling in the right iliac region reached to within an inch from the umbilicus. At 10 A.M. on the 15th her temperature was 100·4°, her pulse 88, and her respiration 24 ; at 6 P.M. her temperature was 99°, her pulse 80, and her respiration 23. On the 16th her temperature was 98°, her pulse 70, and her respiration 23 On the 17th her temperature was 98°, her pulse 68 and her respiration 22. On the 18th her temperature was 97°, her pulse 70, her respiration 21, and so on to complete recovery.

On Nov 2nd she was admitted to Norwood Cottage Hospital and her food and bowels were regulated till the 4th. At 11.30 A.M. on that day chloroform was administered by Dr. C. E. Michael and with the assistance of Mr. J. Sidney Turner and Mr. A. Scott-Turner the following operation was performed : An incision four inches long was made parallel to Poupart's ligament and one and a half inches above it, and the peritoneum was carefully opened at the upper end. The head of the colon was found to be adherent to the anterior abdominal wall just below the incision. It was extremely difficult to find the appendix, which was firmly bound down by a strong meso-appendix adherent throughout its length to the posterior wall of the abdomen and dipping down for a quarter of an inch into the femoral canal, to which it was adherent. A strong and old adhesion also bound it to the ileum. The meso-appendix was pierced at an inch from the cæcum and a ligature which was passed round the appendix at this part gave control over the process during the operation. The adhesions of the appendix to the posterior wall were soft and separable by the nail, but in the process of doing this the soft and swollen appendix was torn in the middle and both ends were at once secured with Spencer-Wells forceps and ligatures of carbolised silk. The separation was then continued till the tip of the appendix had been enucleated from the femoral canal. The strong adhesion to the ileum was then ligatured and tied with silk and the meso-appendix was divided into four parts each of which was separately ligatured. A portion of peritoneum was then dissected back from the appendix above the temporary ligature and a permanent ligature applied half an inch from the cæcum ; the whole appendix was then cut off, a drop of strong carbolic acid was applied to the mucous membranes, and the deflected peritoneum was drawn over and secured by two fine silk ligatures. During the operation the parts were isolated by two flat sponges and pads of iodoform gauze well packed behind the parts. Four deep stout silver wire sutures including the peritoneum and five horsehair sutures closed the wound which was dressed with iodoform gauze wool and a spica bandage The operation lasted for one hour and 40 minutes. The appendix, which was three and a half inches long, was much thickened throughout, the termination being as large as the thumb (male), and it contained fluid stercoraceous matter, and at the distal end a stercolith quite square with well-defined angles, fairly hard, but crumbling on pressure and dry in the centre, having apparently no nucleus of foreign matter.

After the operation the patient's temperature was 98° and her pulse 74 ; at 10 P.M. her temperature was 98·4° and her pulse 80 ; there were retching and a little sickness ; only sips of hot water were given for 24 hours. At 2 A.M. on Nov. 5th her temperature was 100°, her pulse 81, and her respiration 20. A nutrient suppository was given every six hours. In the forenoon her temperature was 99°, her pulse 78, and her respiration 21 ; there was good abdominal respiration. At 6 P.M. her temperature was 99·4° and her pulse 79 ; milk and barley-water were given, one drachm every two hours. On the 6th her temperature was 90°, her pulse 70, and her respiration 21 ; there was slight abdominal pain. On the 7th her temperature was 98°, her pulse 70, and her respiration 20 ; menstruation came on, 10 days overdue ; three pints of milk were given, with beef essence twice a day. On the 8th her temperature was 98·4° and her pulse 72 ; an enema of soap-and-water brought away a good solid motion. On the 9th she had fish and on the 10th she had chicken. On the 11th the wound was dressed for the first time ; union was found to be firm throughout and all sutures were removed. On the 16th she left the hospital quite well.

The case is worthy of record as one of an unusual position of the appendix. Mr. A. H. Tubby in his excellent monograph on appendicitis only mentions one such case as recorded by Sir F. Treves, and this was associated with a femoral hernia and therefore more easily explicable. The condition of the parts during the operation also and the ease with which the more recent adhesions were separated pointed to some ground for determining the period of selection for operation, for had the present case been deferred till a later period it would have been impossible to separate the adhesions which time would then have strengthened.

Upper Norwood.

# Clinical Notes:

## MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

### A CASE OF INOPERABLE CANCER ; FAVOURABLE RESULT FROM OÖPHORECTOMY AND THYROID FEEDING.

By Walter Edmunds, F.R.C.S. Eng.,

SURGEON TO THE TOTTENHAM HOSPITAL ; SURGEON FOR OUT-PATIENTS TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

A woman, aged 36 years, married and with four children, had noticed for two years a tumour in the left breast. It appeared to be an adenoma but on operation it was found to be a carcinoma with infection of one at least of the lymphatic glands. The breast and axillary glands were removed. This was in 1894 and 15 months later a recurrence appeared at or near the scar. This was excised. Except for one or two minute recurrences which were removed under cocaine the patient continued well till October, 1899—five years from the first operation—when she became extremely ill with symptoms of intra-thoracic growth and bronchitis.

stomach, and one patient alone could be fairly said to have died from operation. On the 15 patients who were operated on 17 laparotomies were done.

(*To be concluded.*)

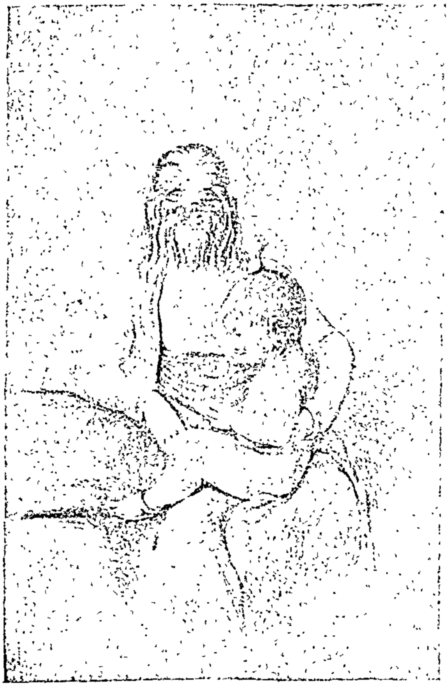
# AN EXAMPLE OF UNIVERSAL HIRSUTENESS.

BY A. J. BALMANNO SQUIRE, M.B. LOND.,
M.R.C.S. ENG.,
SURGEON TO THE BRITISH HOSPITAL FOR DISEASES OF THE SKIN, ETC.

THE extreme rarity of cases of universal hirsuteness and the fact that a portrait of this example of it in his middle age has never been published by anyone else may perhaps be a sufficient apology for my submitting it to the notice of the readers of THE LANCET. The person represented is the son of the Burmese woman named Maphoon who was a classical instance of the same peculiarity, her father, Shevémaong, having also presented the same condition. *Among the most noted instances of universal* hirsuteness are a Russian, Andrian Jeftichjew, and his son Feodor, the hairy family of Ambras, and the Burmese child Krao. The condition is hereditary, it is also congenital, and it is accompanied by a congenital deficiency of the teeth.

In the family to which the person here represented belonged the condition ran through three generations, but Maphoon, who was the youngest of four sisters (she had no brother), was the only one of the four who was affected in the same manner as her father. She had two sons, of whom the younger alone inherited her peculiarity (Fig. 1).

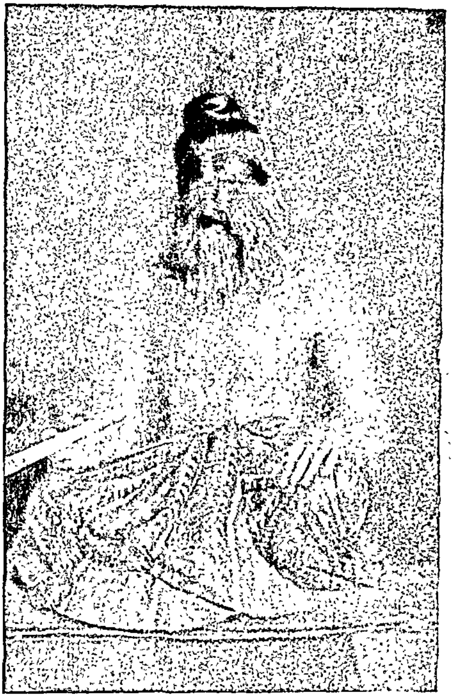
FIG. 1.



Maphoon and her younger son in 1855. From a drawing by Mr. Colesworthy Grant, by permission of Messrs. Smith, Elder, and Co.

Although the condition is congenital it develops itself slowly. Shevémaong and his hirsute daughter and grandson were not born universally hairy but with abnormal hairiness of the ears only; during their infancy and their earlier childhood they became by degrees universally hairy. As to the congenital deficiency of teeth which accompanies this condition Shevémaong at no time had any back teeth. When he was 30 years *old the only* teeth which he had were the four incisors in his upper jaw and the four incisors and the left canine in his lower jaw, but he had never lost any tooth. *His daughter, Maphoon, in adult age had developed only the* eight incisors. As to her son, of whom an illustration is given herewith (Fig. 2), I have no information as to the condition of his teeth. However, in the case of Andrian Jeftichjew *the back teeth of his upper jaw never appeared,* although the row of teeth was complete in his lower jaw. His son Feodor when three years old had an absolutely toothless upper jaw and possessed only the four incisors in his lower jaw.

FIG. 2.



Maphoon's younger son in middle age.

In the case portrayed in this paper the normally bare surfaces, but more particularly the face, are covered with an abundant growth of hair. The face is completely covered with thick and long hair excepting only the red margin of the lips and the upper eyelids, so that his face presents a scarcely human appearance. The hair growing on those regions which are usually bare is soft and fine in texture so as to resemble wool rather than ordinary hair. The hair is more abundant over the shoulders, back, and breast than over the abdomen and the limbs. The palms, the soles, and the last joints of the digits are absolutely bald.

For the portrait of Maphoon and her infant younger son I am indebted to the kindness of Dr. H. P. Cholmeley, whose father, the late Dr. Henry Cholmeley, of the Madras Service, went as medical officer to the escort of *a mission sent to the* Court of Ava by the then Governor-General of India in 1855 and saw the child when he was 14 months old. In the Narrative of the Mission, written by Captain Yule and published by Messrs. Smith, Elder, and Co., occurs the of deep inflammatory redness. On the swollen areola round the base of the nipple were situated six similar but smaller vesicles, each one being distinctly umbilicated. Four of them were on the inner side and the remaining two were on the upper and outer side of the base of the nipple. Over the greater part of the breast the skin was red and tense and the axillary glands were enlarged. There was great tenderness over the whole of the breast The temperature, taken in the mouth, was 100·6° F. and the pulse was 120.

Although the vesicles were suggestive of vaccinia in their appearance and in the history of their development the diagnosis of the case would probably have been somewhat puzzling from the unusual situation of the lesions but for my recollection of the fact that on Dec. 4th I had vaccinated the four children of this patient, none of whom had been previously submitted to the operation. In each case good results were obtained and when the arms were inspected on the tenth day they each presented four perfect though somewhat slowly developed vesicles. In the case of the two-month-old baby there was a good deal of inflammation and I therefore saw the child again on the 16th, when I found the vesicles had been broken and there was then a considerable amount of discharge from them which the mother afterwards told me continued for some days. I advised her to bathe the arm frequently and to dredge over it some boric powder. On questioning her closely I learnt that she had misunderstood my directions and had merely wiped away the discharge with a small piece of dry wool and that she was in the habit of putting the child to the breast immediately afterwards without previously washing her hands. In doing so she no doubt conveyed the vaccine matter directly from the baby's arm to the abraded surfaces on her own left nipple and thus unwittingly infected herself. It may be added that she had not been vaccinated since she was two years old.

## ST. GEORGE'S HOSPITAL.

### A CASE OF PERFORATED DUODENAL ULCER; OPERATION; RECOVERY.

(Under the care of Dr. CYRIL OGLE and Mr. A. MARMADUKE SHEILD.)

DUODENAL ulcer is decidedly more common in men while [illegible]stric ulcer is more frequent in women but the symptoms [illegible]duced by perforation of a duodenal ulcer resemble so [illegible]osely those arising from perforation of a gastric ulcer that a diagnosis between the two conditions is rarely possible before the abdomen is opened. It is very desirable that all cases should be recorded in which an operation has been performed for a perforated duodenal ulcer, whatever may have been the result, so that we may obtain data on which to found trustworthy statistics. For the notes of the case we are indebted to Mr. T. Crisp English.

A man, aged 36 years, walked into St. George's Hospital on July 26th, 1901, giving the following history. Four hours previously, when at work, he had been suddenly seized with violent abdominal pain which completely "doubled him up." This was accompanied by vomiting, collapse, and profuse sweating. In a short time he recovered but as the pain and vomiting continued he went to the hospital. He attributed these symptoms to having eaten half a pound of unripe cherries on the previous evening. In the past medical history of his life there had been no similar attack nor had there been any dyspepsia or other gastric trouble. Free indulgence in beer and spirits was admitted. On examination the patient presented an alcoholic aspect with marked acne rosacea. There was nothing in his appearance to suggest that he was seriously ill but he complained of intermittent colicky pain about the umbilicus and was sweating freely. There was slight tenderness in the epigastrium but there was no distension or rigidity of the abdominal wall which moved freely with respiration; the liver dulness was normal. There were no signs pointing to trouble in the region of the vermiform appendix. The pulse was 80, of good quality, and the temperature was 98·4° F. The only obvious symptoms, therefore, were colicky pain and slight epigastric tenderness and the diagnosis rested between intestinal colic resulting from the unripe cherries, biliary and renal colic, lead colic, and an acute peritoneal lesion in the stage of reaction.

The case was obviously one to be carefully watched and the patient was admitted by Dr. Cyril Ogle. Food by the mouth was withheld and the pain was treated by hot applications; enemata were administered and acted freely; no morphia was given throughout the case. The patient was at first much relieved but in the evening the pain again became severe, whilst the pulse-chart which had been carefully taken showed a progressive increase in frequency. At 6 P.M. it was 96, at 10 P.M. 110, at 12 midnight 116, and at 2 A.M. 128. The abdomen was now becoming markedly rigid and tender and vomiting occurred three times. The liver dulness, which as previously stated was normal on admission, now disappeared to the left of the right nipple line. On the following morning, after a consultation between Dr. Cyril Ogle and Mr. Marmaduke Sheild, a diagnosis of perforated gastric or duodenal ulcer was made and operation was determined upon. Mr. Sheild opened the abdomen in the middle line above the umbilicus (28 hours after perforation) and found free gas and a large quantity of bile-stained fluid in the peritoneal cavity, with early general peritonitis. A rapid examination of the stomach showed that this organ was intact, but on examining the duodenum a small perforation was found on its anterior aspect, just beyond the pylorus. This was closed with a double row of Lembert sutures which held readily and an omental graft was also sewn on the part of the operated area. The peritoneum was then thoroughly irrigated and cleansed with sponges, special attention being paid to the right kidney pouch and iliac fossa. The abdominal wound was closed, no drainage being employed. The operation lasted 25 minutes. The patient was kept on rectal feeding for four days, after which small quantities of peptonised milk were given and the amount was gradually increased. There was no return of pain or vomiting; the bowels were very freely opened by enemata containing one drachm of magnesium sulphate, one and a half drachms of glycerine, and water to four ounces. The wound healed perfectly and recovery was complete, the patient getting up at the end of the third week.

*Remarks by* Mr. ENGLISH.—Very few cases are on record of successful operation for perforated duodenal ulcer. Indeed, Mr. B. G. A. Moynihan[1] in an exhaustive examination of all the recorded cases, could only find eight instances of recovery. Within the last few years this subject has come prominently under the notice of surgeons and it is of importance that all cases, fatal or otherwise, should be reported, that in this way a reliable foundation may be built on which to extend our knowledge of the disease.

In connexion with the above case may be related another case of perforated duodenal ulcer in which death took place shortly after admission to the hospital, on May 11th, 1901. The patient was a dairyman, aged 32 years, who for one week had suffered from indigestion with vomiting. On May 10th at 11 A.M. he was seized with sudden agonising pain in the abdomen followed by severe vomiting and profound collapse. He was taken home and seen by a medical man. The pain and vomiting continued and the abdomen became distended but the patient was not sent to hospital until 9.30 P.M. on May 11th. On admission he was extremely pale and collapsed, the radial pulse could scarcely be felt, the temperature was 96° F., and the extremities were cold. Intense abdominal pain was complained of. The abdomen was greatly distended, tender, and rigid. Liver dulness was completely absent, a tympanitic note being obtained all over. In spite of full doses of strychnine subcutaneously, brandy, &c., he died in about half an hour, 35 hours after perforation. The necropsy revealed advanced general peritonitis, with much gas and fluid in the peritoneal cavity. In the upper aspect of the

---

[1] THE LANCET, Dec. 14th, 1901, p. 1656.

There was also a recurrence in the right (remaining) breast. The bronchitis got better but the patient remained very weak and emaciated, and suffered from dyspnœa on exertion together with frequent asthmatic attacks. In January, 1901, she was seen in consultation with Dr. C. R. Box. There was a tumour in the right breast with enlargement of the axillary glands, also a small flat tumour in the skin behind the left ear. She complained of shortness of breath and attacks of dyspnœa at night. There was evident stridor which was bilateral. The chest was fairly resonant save at the left base where the vocal fremitus was diminished. There was still, therefore, clear evidence of intra-thoracic pressure. The catamenia had ceased during the illness in October, 1899, and had not reappeared. Oöphorectomy with subsequent thyroid feeding was recommended. This was consented to, and the operation was performed on March 11th, 1901. One ovary was found to be atrophic, the other appeared normal. Thyroid feeding was commenced early. On March 26th (15 days after the operation) the tumour in the breast and that behind the ear were both thought to be smaller.

The patient came up to be seen on May 14th (two months after the operation). She was clearly much better and stronger. The tumour in the right breast and the glands in the axilla had almost disappeared and the recurrence behind the left ear was also much smaller and the stridor had disappeared. The breath sounds over the right lung were harsh and over the left lung faint. The stridor had disappeared. On March 4th, 1902 (a year after the operation and commencement of thyroid treatment), the patient had gained flesh, become much stronger, been nearly free from dyspnœa, and, in fact, was quite a different woman There was then a small tumour in the right breast (the patient said that at one time it had completely disappeared), and a lymphatic cord could be felt running up towards the axilla, but there were no enlarged glands in the axilla and the small growth behind the ear had disappeared. Dr. Box reported that the signs in the chest were practically unaltered since the examination of May, 1901—two months after the operation. The thyroid feeding was continued regularly for four months after the oöphorectomy and irregularly up to the present time.

Whatever may be the further history of this case, the great benefit which has been enjoyed for a year has entirely justified the operation. As both oöphorectomy and thyroid feeding were had recourse to this case throws no light on their relative efficiency, but Mr. Stanley Boyd gave no thyroid in his cases, and Mr. H T. Butlin found no benefit from thyroid feeding alone. Mr. F. Page and Dr. W. H. Bishop,[1] however, have recorded a case in which this treatment did much good, and in a recent paper by Mr A. M Sheild[2] reference is made to another case in which great relief is stated to have followed thyroid feeding without oöphorectomy. In cancer of the uterus Dr. R Bell of Glasgow[3] has recorded two cases cured or greatly benefited by thyroid treatment, and quite recently Dr. H. A. Beaver[4] has given us another such case. Thyroid feeding, too, as is well known, will greatly reduce or cure certain goitres, so there is nothing incredible in it benefiting other tumours. As our primary object is clinical and not scientific, it would seem best in the present state of knowledge to give thyroid and to continue it, if it produces no ill-effect, for the rest of the patient's life Occasionally in cancer of the breast recurrence occurs only very late—in another case the disease reappeared 11 years after the original operation. Now one explanation of these cases is that a focus of disease has been lying dormant till it is stimulated into active growth by some change in the metabolism of the body, in which the partial atrophy of the thyroid which occurs with advancing years may be a factor It would therefore be rash to conclude that there can be no use in these cases in thyroid feeding.

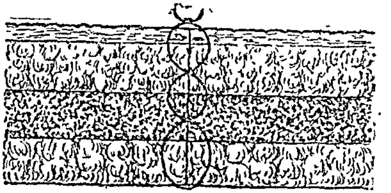
Devonshire place, W.

## A NEW DEEP SUTURE.

By S. L. Woolmer, M.R.C.S. Eng., L.S.A.

I BEG to introduce to the profession a new form of deep suture which has in my hands proved very useful and which must commend itself where sutures have to be applied in superimposed planes. In all laparotomy wounds, in wounds of the body involving muscles and tendons, and in amputations, the general rule has been to suture each layer separately, and of these layers, when they are three, two become necessarily "buried." Only surgeons whose experience is extensive know what are the ulterior results of many buried sutures in spite of their perfect asepticity. The suture which I propose overcomes all objections which can be laid to the account of permanent buried sutures, for the reason that it is only a *temporary* buried suture. It also saves time in its application, as there is only one knot to be tied and one pair of suture ends to be cut off, instead of three, when the suture is applied separately to each plane.

The illustration represents its use in a case of laparotomy, where its application first suggested itself to me. A piece of silkworm gut of sufficient length is threaded with a double needle and the first insertion is made at the bottom of the wound, including subperitoneal fat and peritoneum. The needle is then carried across the peritoneal section and made to emerge in the subperitoneal fat of the other side at a point opposite that of its first entrance. Thence it is carried across the wound and made to penetrate the two layers of the aponeurosis within the rectus muscle. The other needle is now made to embrace the opposite side and is then crossed to penetrate the tegument, the suture being completed by the first needle, which issues from the skin on the opposite side. The suture is tightened with a slight rocking movement and tied in the ordinary manner. In order to effect its removal the silkworm gut is pulled upon on one side of the knot and then cut close, whereupon it recedes within the skin. Slight traction upon the knot is sufficient to withdraw it It will thus be seen that one can secure perfect apposition of a deep wound without any of the disadvantages which accompany a permanent buried suture. I have only applied it in a case of laparotomy, a deep incised wound of the muscles of the forearm, and an amputation of the thigh, but its applications are obvious and extensive For example, it should be the ideal suture in a case of ventrofixation of the womb.



Section of tissues showing suture in position.

I have not seen this form of suture described in any work of reference within my reach and if I am guilty of piracy the act has been unintentional.

Concordia, Argentine Republic

## NOTE ON ACCIDENTAL VACCINAL INFECTION OF THE NIPPLE.

By Frederick Spurr, L.S.A.

ALTHOUGH accidental vaccination is by no means an unheard of occurrence the following case is sufficiently unusual to be worth recording.

On Dec. 25th, 1901, a married woman, 34 years of age, came to me complaining of great pain and tenderness in the left breast, soreness of the nipple, and a painful swelling in the axilla of the same side She had had four children, all of them living, the last confinement taking place two months before She had suckled all her children and had previously suffered from "cracked" nipples She informed me that for several weeks the left nipple had been slightly "cracked" and sore at intervals On Thursday, Dec 19th, she noticed several whitish spots on and around the nipple, which became larger from day to day and more and more painful, but it was not until Christmas Day that she sought advice. On examining the breast I found the nipple swollen, reddened, and having an areola of intense inflammation round its base. This inflamed areola extended for about half an inch beyond the root of the nipple and was quite œdematous in appearance. On the inner side of the nipple itself there was a circular vesicle, one-third of an inch in diameter, with raised margin and a depressed centre, surrounded by a zone

# Medical Societies.

## MEDICAL SOCIETY OF LONDON.

*Discussion on the Treatment of Puerperal Eclampsia.*

A MEETING of this society was held on March 24th, Dr. W. H. ALLCHIN, the President, being in the chair.

Dr. G. ERNEST HERMAN opened a discussion on the treatment of puerperal eclampsia by a paper entitled, "Some Points in the Treatment of Eclampsia." The two points, he said, to which he would confine his attention were (1) Was emptying the uterus the appropriate treatment and would it stop the fits? and (2) the use of the tepid bath in the treatment of the condition. Dr. Herman quoted the teaching of old and recent writers to the effect that emptying the uterus stopped the fits and that therefore this procedure should be the first thing in treatment. He pointed out that although this had been taught for at least three generations its recent defenders tacitly recognised that it still needed proof. He brought forward statistics drawn from the practice of many lying-in hospitals, based upon a large number of cases, and showed that in every institution in which experience was large enough it was found that fits continued after delivery about as often as they ceased with it. He showed that the statement that "after delivery the fits at once cease" could not possibly be reconciled with the facts. But even if the fits did not at once cease, perhaps the acceleration of delivery might yet favour recovery? Dr. Herman inquired if this were so and he found that in the most recent maternities, conducted in the best manner with strict antisepsis, the mortality of eclampsia cases delivered naturally and of those in which the emptying of the uterus was accelerated was about the same. In some institutions in pre-antiseptic times the mortality of accelerated delivery had been in eclampsia cases much higher than that of those allowed to be naturally delivered; and this would probably be so again were it taught that labour in all circumstances should be induced. Dr. Herman then referred to those cases of eclampsia in which death took place by steadily rising temperature and pulse. He thought that the most hopeful and reasonable treatment of such cases was to bring down temperature with the tepid bath. He related a case in which, with a temperature of 105° F. and a pulse of 170, the former was reduced to 102° by the bath and recovery followed. He also referred to a somewhat similar case in private practice.

Dr. J. M. AMAND ROUTH remarked that the prevailing belief in the treatment of emptying the uterus depended on the reasons given for the operation. It was generally admitted that the nephritis was largely dependent upon the toxic condition of the blood, a condition which was largely relieved when the child and the after-birth came away. The treatment by the tepid bath was not always so successful as in the case quoted by Dr. Herman; and he (Dr. Routh) narrated a case in illustration. The temperature, which went up to 107°, was reduced to 101° several times but the patient died. After death the axillary temperature was 109°.

Dr. F. J. MCCANN remarked that puerperal eclampsia was now known not to be due to pressure on the vessels and he quoted some older authors who taught that rapid delivery was not the correct treatment. Morphia and saline injections evidently aided the tepid bath in Dr. Herman's case. The fact that the fits continued after delivery did not prove that emptying the uterus was not the correct treatment. The fits often underwent considerable diminution after delivery though they might not altogether cease.

Dr. W. J. GOW remarked that the actual pathology of the disease was unknown. A certain number of patients in these cases died and others got well whatever was done, and the real question was whether treatment aided the recovery of those who would otherwise die. The appropriate treatment would be to eliminate the poison on which the convulsions depended. Failing this half measures might be adopted such as calming the nervous system. His opinion was that the mere process of induction of premature labour aggravated the fits, though the emptying of the uterus might ultimately relieve them. Morphia or chloroform with an expectant treatment was preferable to more violent methods.

Dr. H. CAMPBELL POPE referred to cases of eclampsia which occurred largely in one particular village in which there seemed to be a special tendency to the disease.

Dr. W. RIVERS POLLOCK remarked that whatever was done violent methods for the rapid induction of labour such as those suggested by Dührssen should not be adopted, though milder methods might be applicable.

Mr. JONATHAN HUTCHINSON, jun., asked whether trephining the head might not be useful. He had seen one case in which the patient, a male, suffering from eclampsia, had received immediate relief in this way.

Dr. R. A. GIBBONS remarked that the etiology of the condition was uncertain. It was, at any rate, a poison which could produce rapid degeneration of the vessels of the liver and other large glands. The patient might die from the intensity of this poison. Anything, therefore, which could dilute the poison was useful and that was why he advocated the use of saline injections. His experience was that the outlook was more favourable when the uterus was empty—though he did not always advocate artificial means. As a means of prevention the urine of pregnant women should be more frequently examined. If there was a large amount of albumin premature labour was undoubtedly indicated even although the patient seemed to be in apparent health. He mentioned cases in illustration.

Dr. G. F. BLACKER questioned the advisability of interfering with the uterus. There were, in his opinion, three indications: (1) to lessen the reflex excitability of the nervous system; (2) to eliminate the poison, which could be done by venesection, even to the extent of 500 cubic centimetres at a time; and (3) to dilute the poison remaining in the blood which could best be done by the intravenous injection of saline solution up to about 1000 cubic centimetres at a time.

Dr. M. HANDFIELD-JONES expressed himself as being in general agreement with the author of the paper. He referred to a woman in whom three pregnancies were all attended by eclampsia. He emphasised the importance of treating the renal inadequacy which appeared to exist in cases of eclampsia, and in some of these cases the emptying of the uterus might very well be considered before the convulsions supervened. There were enormous differences in the clinical features of the condition. He would certainly not abstain from the operation of inducing labour in all cases, even when in presence of eclampsia.

Dr. HERMAN, in replying, said that his chief object had been to controvert the emphatic statement in the current text-books that when the uterus was emptied the fits ceased. As a prophylactic treatment he fully believed in inducing premature labour when there was much albumin in the urine. In treating the fits bleeding was a good treatment. If labour was induced in presence of convulsions Cæsarean section was undoubtedly the best method.

## HARVEIAN SOCIETY OF LONDON.

*Exhibition of Cases.*

A MEETING of this society was held on March 20th, Mr. W. WATSON CHEYNE, the President, being in the chair.

Mr. E. W. ROUGHTON showed a child, aged seven months, after Operation for Intussusception. Four weeks previously the child was brought to him with the complaint that it had been sick more or less continuously since last Christmas, and that on the previous evening it was taken considerably worse and began to pass blood and slime. Intussusception was at once suspected, and on palpation a small swelling was found above and to the right of the umbilicus. Injection was not resorted to but the abdomen was at once opened and an intussusception of the ileo-cæcal variety was found which had only travelled as far as the hepatic flexure of the colon. It was reduced with ease. Mr. Roughton afterwards noticed that the vermiform appendix presented a bruised appearance, and he accordingly removed it.—The PRESIDENT said that he had taken a fancy to combining the two methods—that of injection and of abdominal section. He opened the abdomen and located the intussusception and then injected fluid slowly per rectum. Then if the fluid did not seem to be doing good the bowel could be brought out and the intussusception removed.

Mr. ROUGHTON showed another case in a child, aged 13 months, who was operated upon at the age of four months when the symptoms had lasted 24 hours. He reduced the intussusception easily except the last two inches, but that occupied a quarter of an hour and was very troublesome.—Dr. W. CAYLEY supported the combined method of reducing first part of the duodenum just beyond the pylorus was a sharply punched-out ulcer of about the size of a threepenny-piece, with a small circular perforation at the bottom of it. There were no adhesions or thickening round the ulcer.

The first case forms an excellent illustration of a fact which is, perhaps, not sufficiently emphasised—namely, that there frequently exists a well-marked stage of reaction in acute peritoneal lesions. Failure to recognise this has frequently led to errors in diagnosis and serious delay in treatment. *Three distinct stages may be described in these cases.* First, the stage of collapse, which is usually profound and which with the agonising pain and vomiting forms the clinical condition known as "peritonism." A history of the *sudden onset of these symptoms in a healthy individual* is strongly suggestive of some very serious lesion within the abdomen and forms a valuable aid in the diagnosis of the condition. *The second stage is that of reaction and this may prove very misleading.* The patient rallies from the initial shock, the general condition improves, whilst the pulse and temperature may be normal and the abdomen may present no evidence of serious mischief. The patients may, as in the case related above, walk into a hospital with the contents of their intestines leaking into the peritoneal cavity. If first seen in this stage, as is frequently the case, a too hopeful view is apt to be taken, the patient is not carefully watched, and thus by delay the chances of recovery are minimised. Should morphia, as is usually the case, have been given freely the symptoms are still further obscured. The third stage is that of the onset of obvious peritonitis, in which the general condition progressively deteriorates, the pulse increases in frequency, and the condition of the abdomen points unmistakably to a widespread infection of the peritoneum. Progressive quickening of the pulse is a sign *of the utmost importance.*

It is noteworthy that vomiting in cases of perforated duodenal ulcer is usually pronounced and persistent from the beginning, contrasting with the vomiting in perforated gastric ulcer, which occurs as an initial symptom in about 40 per cent. of the cases and rarely persists. The mortality of the affection is necessarily very high. Mr. Moynihan places the mortality of cases operated upon at 84·6 per cent. It must, however, be remembered that it is certain that many of the fatal cases are not recorded, whilst, on the other hand, it is probable that some perforations are sealed by the formation of adhesions and that a natural cure results. In still other instances abscesses have formed and these have been known to "*track down*" behind the peritoneum. *One* of the principal operative difficulties is to find the ulcer when this is small and situated towards the posterior aspect of the gut; indeed, the lesion has repeatedly been "missed" by operators and has actually only been discovered with difficulty at the necropsy.

Dr. Cyril Ogle and Mr Marmaduke Sheild kindly gave me permission to publish this case.

---

# EDINBURGH ROYAL INFIRMARY.

## A CASE OF TABES WITH ACUTELY DEVELOPED ATAXIA IN WHICH GREAT AND RAPID IMPROVEMENT RESULTED FROM FRENKEL'S PLAN OF TREATMENT.

(Under the care of Dr. BYROM BRAMWELL )

THE value of Frenkel's *treatment of locomotor ataxia* is by no means yet generally acknowledged and therefore the following case will be of interest. In the rapid onset of the ataxia and its almost equally rapid disappearance, even though Frenkel's treatment was employed, Dr. Bramwell's case differs markedly from most cases of tabes and therefore it does not, perhaps, prove very clearly the benefit of this *form* of treatment.

The patient was a married man, aged 35 years. For five years he had been a barman and for 16 years previously a ship-steward. He was admitted into the Edinburgh Royal Infirmary on Jan. 22nd, 1902, because of inability either to stand or to walk. He had enjoyed good health until the present illness commenced. He absolutely denied having had syphilis or gonorrhœa There was no suspicion of alcoholic excess; his average allowance of alcoholic liquor was four glasses of beer per week; he did *not* take more than 12 glasses of whisky per annum. He was not a heavy smoker. For six months before the inability to walk developed he had had some, but only slight, shooting pains in the legs, more especially the left leg, which was sometimes swollen at night, the result, he thought, of varicose veins. He had occasionally experienced a dull *pain in the* back and some little difficulty in micturition, having to "force" a little to get the urine away. The inability to walk developed rapidly on Jan. 13th, 1902. For a fortnight before this date he had felt some stiffness and "pins and needles" in his legs and feet but had no difficulty in walking *in the dark. He was in the habit of walking from his place* of business to his house—a distance of about a mile—every night at 12 o'clock. On Sunday, Jan. 12th, he walked three miles. On the 13th he had great difficulty in walking from one room to another and on the 14th he was quite unable either to stand or to walk.

On examination it was found that the inability to stand and walk was due to ataxia. There was no paralysis. The muscularity of the legs was good. The movements of the legs were wildly ataxic. There was no ataxia in the arms. When the eyes were closed there was *total loss of the* sense of position, both during and after passive movements, in the lower extremities. Occasional shooting (lightning) pains were complained of in the legs (thighs and calves). There was some varicosity of the veins of the left leg. The left calf measured 12½ inches and the right calf 11¾ inches in circumference. The patient was a short, spare man. The knee-jerks and Achillis-jerks were completely absent, even after reinforcement; the deep reflexes in the upper extremities were present but not exaggerated; the jaw-jerk was present. *The direct muscular excitability of the anterior* and posterior muscles of the leg and of the quadriceps group was slightly increased; there was no myoidema contraction. The plantar reflex was very active in both legs, the toe *movement being flexion; the cremasteric reflex was absent* on both sides; the abdominal reflex was present but slight. The pupils were unequal in size and markedly dilated; the right measured eight millimetres and the left 10 millimetres; *they were quite insensible to light* and only contracted very slightly in the act of accommodation, the right pupil becoming six millimetres and the left eight millimetres in size; they did not dilate on powerful stimulation (pinching and faradic irritation) of the skin of the neck. There was well-marked thoracic and ulnar analgesia and there were considerable analgesia and anæsthesia of the lower extremities. Biernacki's sign was not present. There was also marked analgesia of the muscles of the calf. There *was some, but only slight,* hypotonia. There was no girdle sensation. A slight dull pain in the "small of the back" was occasionally experienced. Slight difficulty in micturition (necessitating "forcing") was occasionally *experienced; the* bowels were regular; there was little or no loss of sexual desire and power. There had never been diplopia or ptosis; the ocular movements and the optic discs were normal; the special senses were normal; there were no crises and no trophic or vaso-motor derangements. The mental functions were unimpaired, there was no articulatory defect, and there were no facial or tongue tremors.

A striking and rapid improvement resulted from Frenkel's plan of treatment. *On Jan. 22nd the patient was unable to stand or to walk, the movements of the legs being wildly* ataxic. Frenkel's treatment was commenced on the 27th. In the course of 10 days (on Feb. 7th) the patient was *able to stand and to walk with the help of a go-cart.* A week later (the 14th) he was able to walk with the help of two sticks. On March 5th he could walk steadily and well with sticks and he could also walk across the room fairly *well and without a marked ataxic gait without sticks*—i.e., totally unsupported.

*Remarks by Dr.* BRAMWELL.—The case is interesting because of the *following features*;—1. The absolute and apparently quite straightforward denial of the patient that he had ever had syphilis or gonorrhœa. 2. The rapidity with which the ataxia was developed. I have lately analysed 155 cases of tabes which came under my notice and in only three of them was the ataxia very rapidly developed. 3. The dilated condition of the pupils. In 104 of the 155 cases of tabes which I have analysed the size of the pupils was mentioned in the notes. *In 69 of these 104 cases, or 66·3* per cent., the pupils were contracted (below three millimetres); *in 27 cases, or 25·9 per cent.,* they were of medium size (between five and three millimetres); and in only eight *cases, or 7·6 per cent*, they were dilated (above five millimetres). 4. The rapid improvement which resulted from Frenkel's method of treatment.

number of rings and patches studded over the upper arms and deltoid regions. The faint red margin and the fawn centre were conspicuous and offered a contrast to the seborrhœic patch on the back with its greater degree of scaliness and rougher surface.

Mr. C. W. Cathcart showed the following cases:—1. A man whose right arm had been caught between two rollers in a paper factory. He presented every indication of complete paralysis of the brachial plexus as well as complete loss of sensation in the areas supplied by these nerves; not even the intercosto-humeral nerve had escaped. There seemed to be a slight action of the subclavius and the serratus magnus muscles. On making an incision in the neck no trace of the brachial plexus could be found, but merely a mass of scar tissue. The separated ends were so distant that the clavicle was cut through and a graft of the two ends was made. As yet no advantage had resulted from this operation. 2. Mr. Cathcart contrasted the above with a case of partial rupture (the lower cords) of the left brachial plexus in a man, the result of a fall. The eighth cervical nerve and the first dorsal nerve had been ruptured as well as part of the seventh cervical nerve possibly. 3. A man, aged 66 years, who had suffered from a hernia for some time. It had come down on several occasions but had always been replaceable except on this last occasion when it could not be reduced. He was operated on 24 hours after the strangulation had occurred and the bowel was then quite gangrenous. As the patient seemed to be fairly strong the gangrenous part of the bowel was excised and the healthy extremities were at once sutured with silk sutures. Recovery was going on satisfactorily. 4. A child who had fallen and later had developed cerebral symptoms, unconsciousness, fits, restlessness, and dilatation of the pupils. There had been a discharge from the right ear for some time antecedent to the injury but when examined this discharge was mixed with blood. The indications were enough to warrant the opening of the skull in the mastoid region. This was done but no abscess was found. On opening the dura mater, however, much blood-stained fluid escaped, as there had been fracture of the base of the skull. The child at once improved and the case had gone on successfully since. 5. A case of Bazin's Malady in a woman who was first seen in November, 1901, with Multiple Ulcers on the Legs. These were not thought to be syphilitic or tuberculous then and so they were scraped and carbolic acid was applied. Mr. Cathcart expected that they would have healed up at once but in a few days they were found to be again breaking down. The ulcers were treated again still more energetically. Dr. Allan Jamieson was asked to see the case and he diagnosed it as one of Bazin's disease. Mr. Jonathan Hutchinson had described this disease as an intractable form of ulceration most often mistaken for syphilis, but it was probably a tuberculous lesion, though no tubercle bacilli had been found to be present. The case had improved greatly under salicylic and creasote plaster with a later application of ichthyol and zinc plaster.

Dr. Byrom Bramwell showed two cases. 1. A man in whom the Stereognostic Sense in the Left Hand was for a time completely lost. He did not know if an article in his pocket were a coin, key, or knife. 2. A case of Bright's Disease in which Marked Diuresis resulted from the administration of boric acid when other diuretics had failed to increase the urinary flow.

Mr. H. Alexis Thomson demonstrated the following cases. 1. A patient, a young man, after Suture of a Penetrating Wound of the Stomach. A gouge had been pushed through the abdominal wall below and to the left of the umbilicus and being directed upwards and backwards had penetrated the anterior wall of the stomach close to the lesser curvature. The case seemed at first trivial as the patient's symptoms were not severe. Later, however, he began to vomit blood and although a probe entered only three quarters of an inch into the wound it was determined to open the abdomen. On doing so the bowels were found to be covered with blood and an opening allowing the tip of the finger to be passed in was present in the stomach. 2. A man, aged 61 years. after Operation for Irreducible Inguinal Hernia containing a Large Diverticulum from the Urinary Bladder.

Dr. G. A. Gibson showed two cases. 1. An Aberrant Case of Polyneuritis simulating Landry's Disease. The patient had had no infectious disease since childhood or any accident except a fall on the bridge of a steamer due, Dr. Gibson thought, to the disease and not a cause of it. There was an almost complete paralysis of both lower extremities as well as of the right arm and, to a great extent, the left also. There was a total loss of all reflex phenomena as well as a loss of tone in the muscles which began to waste. There was no diminution in the sensibility but some subjective disturbances, as pain on pressure. There was no reaction of degeneration. 2. A patient with Pyloric Stenosis in whom pyloroplasty had been done by Mr. Cotterill. The patient was 45 years of age and he had suffered from dyspeptic symptoms for three years. About three months previously he had suffered greatly from vomiting and had lost weight rapidly. There was a total absence of free hydrochloric acid in the gastric secretion as well as a great diminution of the total acidity; no lactic acid was present. The stomach reached to one inch below the umbilicus. No peristaltic movements occurred in the gastric walls and splashing easily took place. Examination of the blood showed no pathological leucocytosis. The case was not one of atonic dilatation. Dr. Gibson was inclined to think that it was not a malignant contraction. Mr. Cotterill found it to be a cicatricial contraction of the pyloric opening. The patient had increased nearly one stone in weight since the operation.

Dr. Gibson also showed a Brain from which a cerebellar tumour had been removed.

Mr. Wallace showed (for Professor Chiene) three cases of Injury to the Head. 1. A patient who had received a severe injury to the right side of the head three years ago. The wound was treated and he recovered well at the time, but a year subsequently he developed fits to a very great degree, 180 or so in 24 hours, and even passed into the status epilepticus frequently. Professor Chiene operated, reflecting a large flap, and found the scalp, the dura mater, and the bone all united. These were separated from one another and the patient now felt better and had had no recurrence of the fits. 2. A boy, aged 11 years, who received an injury to the forehead. 10 days subsequently his mental character underwent a change; he quarrelled and fought with his brother and later developed convulsions. This condition continued for a year. At the operation a depression was found, the bone was thickened, and the dura mater was adherent. These were separated and for a time improvement seemed to continue but now this was very doubtful. 3. A patient who received an injury to the left parietal region of the skull 15 weeks previously. There was some paresis of the right arm and leg and operation seemed to be indicated as he was beginning to develop fits.

Dr. Norman Walker demonstrated three cases. 1. A child showing Urticaria Pigmentosa. The yellow raised spots when examined microscopically were seen to consist of Ehrlich's mast cells. The prognosis was that when such patients reached the age of from 18 to 20 years the disease disappeared. 2. A case of Rodent Cancer of the Tip of the Nose in a woman who was treated and cured by arsenious acid. The part so treated sloughed and came away *en masse*. There was a tiny recurrence in this case necessitating a second application but the cure was now complete. 3. A case of Mild Ichthyosis in a boy. This disease was commonly stated to be congenital. As a matter of fact it was not so but was hereditary, commencing at the second year of life. The child was being treated by small doses of thyroid extract.

Dr. Jamieson demonstrated the new Marshall and Wood's Lamp for the treatment of Lupus by light, which has just been installed in a room set apart for this treatment and for that of lupus and rodent ulcer by the x rays.

---

# ROYAL ACADEMY OF MEDICINE IN IRELAND.

## Section of Medicine.

### *Pseudo-elephantiasis.—X Rays in Medical Diagnosis.*

A meeting of this section was held on March 7th, Sir Christopher Nixon, the President, being in the chair.

Dr. William J. Thompson showed a case of Pseudo-elephantiasis. The patient, a woman, 64 years of age, had been admitted to Jervis-street Hospital, Dublin, a few days previously with an enormously enlarged spleen which extended downwards almost to the crest of the ilium and inwards as far as the umbilicus. Further examination revealed an abnormal condition of the left leg which she had never before shown to anyone or spoken of in any way. It might, Dr. Thompson thought, be classed as a case of pseudo-elephantiasis. Her family history was good. both her parents lived to advanced an intussusception. The great drawback to relying upon the older method of reduction by water alone was that it was impossible to tell whether the intussusception had been completely removed.—Dr. LEONARD G. GUTHRIE asked whether Mr. Roughton had had experience of the results of leaving such cases alone. He had met with one case of so-called "nature's cure." A child, aged 15 months, had signs of obstruction lasting for some days. Six months previously there had been pain in the abdomen and the passage of blood and slime. A medical man who was called in told the mother that the bowel had become telescoped and that such cases were best left alone. Some days later the patient passed a gangrenous mass per anum. The child recovered for a time, but later was brought again and operated upon, when there was no trace of either cæcum or vermiform appendix. At the junction of the small and large bowels there was a constricted portion one and a half inches long which was twisted one and a half times on itself. The surgeon dissected that, used a Murphy's button, and sewed the ends together. The child, however, died in a few hours.—Mr. ROUGHTON, in reply, said that he did not propose to try the combined methods mentioned by the President. He had only operated upon three cases of intussusception and they had all recovered. Injection had not been used. He thought the fluid must distend the bowel and that would probably be a greater source of shock than manipulation outside. He did not see why such cases should not recover if operation were done sufficiently early, say within 24 hours.

The PRESIDENT showed a man who had Fractured both Patellæ, one of which had been treated by wiring and the other not, and he remarked that the secret was not to put the leg in a splint but to make the patient walk as soon as possible.

The PRESIDENT also showed a boy who a year ago fell from a parapet, a distance of 20 feet, and Fractured the Left Femur above the Condyles. When seen the lower end of the upper fragment was in the lower part of the popliteal space behind the tibia. Reduction was tried but every time the force was relaxed it shot back again. The application of heavy weights was also tried but without permanent success. Eventually he made a long incision, turned back everything, and exposed the bones. It was found that not only was the femur fractured across but the condyles were down in the joint and the ends of the bones went in between the condyles, separating the two halves. He therefore nailed on the outer side a plate of aluminium, fastening it with silver tacks. The leg was put into a splint and was kept there for a long time because the bone was so thin. For a time the lad had a stiff knee, but he could now bend it to a right angle. The plate was still *in situ*. He found that the use of the plate was an excellent measure in such cases and he had treated several by it It would be an advantage to have the plate and the nails of the same metal to obviate any possible electric action.

Mr. J. JACKSON CLARKE showed a boy the subject of Severe Spastic Paralysis one year after operation. He had shown the boy before operation and shortly afterwards. The right leg had been particularly stiff but was now more useful, though he still walked plantigrade. There had been a lot of clonic movement, and he performed an elongation of the tendo Achillis on the right leg. Instruments had been left off during the day but were resumed at night. He did not believe that tendon transplantation had been very useful for the condition. He thought that the prognosis after operation in such cases was more hopeful than he had been taught, and than he at one time believed.—Dr. E. CAUTLEY believed that anything which would assist such children to walk would also assist their mental development. He thought that in all cases of spastic paralysis any operation which would enable the patients to stand, and later to walk, should be done, even though the child might not be mentally competent. Once they associated with other children and could play with them the mental and physical development was improved.

Dr. GUTHRIE showed a case of Charcot's Disease in both Hip-joints in a woman, aged 44 years. 12 years ago she had slight pains in the limbs which did not last long. Three years ago they were much worse and of a lancinating character and there was numbness about the soles of the feet. At about that time a sudden swelling arose in the neighbourhood of the right hip but it was painless. But she thought that the bone was out because, she said, she could hear the bones rattle. Six months ago the other hip was similarly affected. The patient had the Argyll-Robertson pupil and the left pupil was larger than the right. Romberg's sign was marked and she had absence of the knee-jerks on both sides.

Dr. GUTHRIE next showed a case of Arrested Growth of the Forearm following Fracture, with Ischæmic Paralysis, in a man, aged 58 years. The condition of Volkmann's ischæmia was of 50 years' duration. At nine years of age the patient fractured both bones of his left forearm and tight bandaging and subsequent ulceration resulted in firm flexion of the wrist when the splints were taken off. The fingers were bent into the palm of the hand and there was no use in the fingers. Operations had since been performed with the view of increasing the length of the contracted tendons. There was a difference of two and a half inches in the measurement of the two sides. The bones of the left forearm were small, infantile in appearance, and delicate. The fingers were dwarfed and stumpy and somewhat glossy. Reaction to faradism could be obtained in both flexors and extensors. The condition had been known to follow the application of Esmarch's bandage. Volkmann thought that the condition was due to a condition similar to rigor mortis produced by stoppage of the circulation, while others were of opinion that it was a purely nervous phenomenon. The previously described cases had been in children and had not been watched long enough.—Mr. RAYMOND JOHNSON and Dr. JAMES TAYLOR took part in the discussion which followed.

## EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

*Exhibition of Cases, a Specimen, and a Lamp for the Treatment of Lupus.*

A SPECIAL clinical meeting of this society was held on March 19th, Professor T. R. FRASER, F.R.S., the President, being in the chair.

Mr. F. M. CAIRD showed (1) a girl after removal of an Intracranial Tumour; and (2) a woman after partial removal of an Intracranial Tumour.

Dr. FRANCIS D. BOYD demonstrated a case of Congenital Paraplegia.

Mr. DAVID WALLACE showed a patient after removal of 44 inches of Tuberculous Intestine.

Dr. W. ALLAN JAMIESON exhibited four interesting cases. The first was a case illustrating the combined features of Lupus Vulgaris and Lupus Erythematosus on the same patch. A country girl, aged 17 years, presented a cluster of nodules arranged in an annular form on the left cheek, conforming generally to the appearance of a patch of lupus vulgaris, but in the centre of the patch was a scaly spot of the size of a pea, the scales having the splintery character of those in lupus erythematosus, and on being removed showing the usual epidermic tags on their under surface. On the right ear near the lobe was a distinct patch of lupus vulgaris. The disease had lasted for a year. The second case was one of Lupus Erythematosus after prolonged treatment by quinine. The patient had been under observation for 16 years but the disease had existed longer. In June, 1900, there were two patches of the size of a crown piece on each cheek, no treatment having had any decided result. The patient was then placed on quinine, five grains three times a day, and up to the end of January, 1902, she had taken in all six ounces. Improvement began at once, and the former diseased area was now a fine scar. She had found out for herself what Unna so strongly insisted on—that dry applications suited best locally. The third case, one of Para-keratosis Variegata (Unna) was one of those which were shown by Dr. Jamieson at the meeting of the British Medical Association in Edinburgh in 1898. Little alteration had taken place since then. There was still the same mottling of the skin, the same smoothness and absence of hair, and the same crimson-red appearance which led Unna to term the cases "red men." The first case which Dr. Jamieson had met with was in a female, many years since. He still regarded the cases as akin to lichen planus. No treatment had produced any result. The fourth case was one of Pityriasis Maculata et Circinata The patient, a man, aged 40 years, had had a patch of seborrhœic dermatitis of the size of a florin midway between the scapulæ for three years, but a month since a blotch presenting the aspect of pityriasis rosea had appeared on one shoulder and there were now quite a vaccinia. A few days showed that it was only vaccinia with a generalised eruption. Dr. Hingston Fox went on to refer to the records of generalised vaccinia, pointing out the various forms: accessary vesicles around the primary ones; pocks elsewhere from accidental auto-inoculation; and a truly generalised rash as in this case. Acland had described it as "vaccinal eruptive fever," the eruption appearing from the fourth to the tenth day. The distribution was irregular. Recent cases described by Dr. Morrow, Dr. T. Colcott Fox, and Dr. W. T. Freeman showed implication of the whole *skin-surface, upper limbs, and upper half of the trunk,* and wrists alone respectively; but the face, mucous membranes, palms, and soles were scarcely ever affected. The irregular location, the multiform character of the rash, with quickly-maturing vesicles, and the slight prodromata and malaise, served to establish the diagnosis. In some cases the eruption had followed ingestion of vaccine lymph by the digestive system; in others an irritable state of the skin, congested by pyrexia, or broken in its continuity by dermatitis, seemed to be the cause. In the present case probably the catarrh of the fauces with pyrexia had determined the outbreak of the eruption and its distribution had been influenced by friction. In the often difficult diagnosis of modified small-pox it was well to bear in mind the occasional occurrence of generalised vaccinia.—Dr. Denning quoted a case where the patient had gone into the country from London in which pocks appeared, pronounced to be those of small-pox, 16 days after a successful vaccination.—Mr. F. R. Humphreys said that he had seen a case where a vaccination spot appeared under the clavicle and a rash on the face.—Mr. John Adams said that for a rash to appear after vaccination was a not unlikely thing. He had met with marked cases of vaccinia rash. These appeared frequently about the neck and vaccination was unlikely to take after a patient had been infected with small-pox, but he had known a child to be well vaccinated after four days' exposure to infection of small-pox who a little later developed small-pox. The malaise after vaccination after 20 years of age was considerable and seemed greater in revaccination than in primary vaccination. A great distinction between variola pocks and those of vaccinia was the constant size of the former and the variable size of the latter. Inoculation of vaccinia by swallowing seemed to be unlikely.—Mr. E. Carnall mentioned a type of rash after vaccination which was confined to the arms and face; it was not glazed and was short-lived.—Mr. F. J. P. Daly said that there were three types of rashes appearing after vaccination: papules over the back of the wrist, a pustular form, and an erythematous eruption scattered all over the skin, except on the face and hands, disappearing in a week.—Dr. Hingston Fox thought that Mr. Humphreys's case was a self-inoculated one and that Dr. Denning's case was one of small-pox. —Dr. John Adams quoted a case of a vaccinated child who had slept with a case of virulent small-pox.—Dr. W. A. Milligan showed a case of Paget's Disease. The patient was a woman, aged 52 years, who had married at 39 years of age, and had a child at the age of 40 years, whom she had suckled for 10 months. Menstruation left her suddenly at 45 years, and during the time from suckling the child up to 12 months previously the only thing that troubled her was a milky discharge every now and again. 12 months previously the left breast began to itch, and then the nipple became red and slightly ulcerated; it scabbed over but never healed. The redness gradually spread down over the whole areola which presented a raised brawny appearance. The breast gradually got more and more painful. When examined six weeks previously an enlarged gland was found in the axilla, but there was no definite involvement of gland tissue. Microscopic examination of the scrapings showed the presence of psorospermia.—Mr. J. H. Targett considered that the presence of psorosperms completed the case, but he did not think that they were the cause of the disease.

**Liverpool Medical Institution.**—A meeting of the Pathological and Microscopical Section of this institution was held on March 20th, Dr. W. B. Warrington being in the chair. (Dr. J. Barr occupied the chair during the later part of the meeting.)—Dr. Arthur Wallace showed a specimen of Tuberculosis of the Body of the Uterus removed by vaginal hysterectomy from a married woman, aged 40 years. The endometrium was chiefly affected, but the disease had also extended into the muscular layer. There was no evidence of tuberculosis in any other part of the body, so that the condition was probably the rare one of primary corporeal tuberculosis.—Mr. J. P. Martin showed a Hydrocephalic Brain from a boy, aged one and a half years. The circumference of the head was 23 inches and the weight of the brain was 17 ounces.—Dr. Warrington showed a specimen of Tubercle connected with a Small Artery in the Sylvian Fissure in a case of Tuberculous Meningitis. In the cerebro-spinal fluid withdrawn by lumbar puncture from the case lymphocytes were numerous but there was no other type of leucocyte.—Dr. Warrington also showed a specimen of blood from a typical case of Pernicious Anæmia. Megaloblasts were present but few in number, and also red cells with many granular particles deeply stained with methylene blue; these were regarded as degenerating megaloblasts.—Dr. R. J. Ewart showed specimens from cases of Bronchiectasis and Atrophy of the Cerebellum.—Dr. Warrington, Dr. A. J. Campbell, and Dr. A. S. F. Grünbaum took part in the discussion on the various specimens.—Dr. E. E. Glynn read a paper entitled, "Bacterial Investigations of the Water of Public Swimming Baths." He had directed his attention to the following points: (1) the total number of bacteria present in the water of the first-class and second-class baths at the beginning and end of the day; (2) the number and nature of the pathogenic organisms present; and (3) the source of the organisms. Samples of water were taken in sterilised flasks and plated on agar within an hour of leaving the bath; these plates were incubated at 37° C. and the number of bacteria present in a cubic centimetre of the bath-water was estimated. The colon bacillus was demonstrated by the method of Dr. McConkey—i.e., culture on bile salt agar. The majority of the observations were made at baths which were filled with fresh water every morning always derived from the same source. This water was practically sterile, containing less than three bacteria per cubic centimetre. An hour after the baths were opened the water gave 46 bacteria per cubic centimetre; these were derived mainly from the air and the walls of the baths, as a series of experiments showed that at the temperature of the baths (21° C.) the organisms concerned—i.e., those which grew on agar at 37° C.—did not multiply to any considerable extent. During the eight hours of the night the number of bacteria therefore rose from three to 46 per cubic centimetre; if this rate of increase were maintained at 9 P.M. the number should be about 200 per cubic centimetre. The examination of the water in the first-class plunge bath at 9 P.M. on five different occasions during the months of June and July gave an average of 4676 bacteria per cubic centimetre, the average number of bathers being 292; samples collected in the second-class bath on three occasions contained an average of 11,970 per cubic centimetre, the average number of bathers being 186. A calculation based on the capacity of the baths showed that the water removed from the skin and hair of each bather contained between 4,000,000,000 and 6,000,000,000 bacteria, excluding moulds and others which did not grow at 37° C. One source of pollution of the bath arose from a tiled corridor, about four feet wide, running round between the edge and the dressing-boxes; on this both the bathers and those waiting to bathe walked, with the result that soon after opening this was more or less muddy. To avoid this a bath should have two corridors—an inner one between the bath and the boxes and another outside the boxes, the latter being open back and front. With regard to the organisms discovered in the water streptococci were never found and staphylococcus aureus and citreus very rarely; staphylococcus albus was abundant in three varieties—pyogenes albus, epidermidis albus, and cereus albus. Bacillus coli was present in the bath at the end of the day to the number of eight per litre for each bather in the first-class and 48 for each bather in the second-class. Probably typhoid fever was never contracted in baths such as those investigated and the swallowing of water of the type analysed was quite innocuous. Various complaints had from time to time been ascribed to infection in baths but with doubtful accuracy; some who bathed constantly in the open complained of lassitude after swimming in a public bath; this could not be due to the quality of the water, but to its temperature and to defective ventilation. Liverpool was peculiarly fortunate in the number of its baths and the excellence of the water supplied to them.—In the discussion which followed the following speakers took part: Dr. W. Permewan, Dr. Barr, Dr. E. L. Anderson, Dr. Grünbaum, Dr. Matthews, Dr. Kelly, Dr. T. B. Grimsdale, and Dr. Bennett.

**Childhood Society.**—A meeting of this society was held on March 20th, Dr. James Kerr being in the chair. —Dr. Arthur Newsholme read a paper on the Lower Limit of ages, neither of them had ever been abroad, and she had never been out of the country. She had always been strong and healthy and had been a domestic servant for 40 years. About 30 years ago she first noticed a swelling in the upper and outer part of the leg, about the region of the great trochanter, which came on very slowly, gradually extended inwards (surrounding the leg) and downwards. This swelling at first was always moist on the surface, so much so that it kept her underclothing damp but, as far as the patient remembered, never stiffened the linen. In about seven years the whole leg down to the ankle was involved. At the time of her change of life, 23 years ago, she had some very severe attacks of uterine hæmorrhage which necessitated her resting in bed and she affirmed that while so resting the swelling in the upper part of the leg commenced to get smaller. She was never married and never had any trouble at her menstrual periods. The leg was at present about the same as it had been for the past 15 years, except that the exudations had stopped and the surface had lately become very dark in colour and quite rough. There were great thickening and enlargement between the knee and the ankle-joint. The measurement at the thickest point was 26 inches, at the same point on the right leg it was only 11½ inches. Since her admission into hospital the swelling had become much softer and less resisting, probably due to the rest in bed. The foot and as far on the ankle as the shoe fitted was scarcely swollen and the swelling above this hung quite over the foot when the patient stood up. From the thigh to the knee the swelling was not nearly so marked; the thickest part measured 24 inches and the measurement at the corresponding point on the opposite leg was 15 inches. Up to the time of her admission she was at work as a cook and had never had any pain. The urine contained no trace of albumin, sugar, or chyle. The woman was pale, thin, and emaciated, and she stated that for the past year she has lost flesh rapidly.—Professor E. J. McWeeney remarked that save for a moderate polymorphonuclear leucocytosis and an increase in large hyaline leucocytes of transitional type the blood exhibited no abnormality. He had observed three cases of this kind. In one lymphorrhœa was a prominent feature and the patient, a young man, ultimately died from septic poisoning. The two others were middle-aged men and were treated by amputation. In both cases he had satisfied himself by dissection that the cause of the lymphatic obstruction was chronic tuberculous lymphangitis. The histological features were interesting and comprised immense thickening of the epidermis, especially of the stratum lucidum and coroneum, without thickening of the true skin but with dilatation of the lymph spaces and general œdema. All fibrous structures showed marked overgrowth. The lymphatics were accompanied by streaks of small old infiltration, in which encysted giant cells of tuberculous character were embedded. The skin was about 10 or 12 times as thick as normal skin. In both of these cases he had convinced himself that the pseudo-elephantoid condition was of tuberculous origin and had confirmed his view by discovering the bacilli in one of them.—Sir George F. Duffey stated that not long ago he met with a similar case of pseudo-elephantiasis of both legs in a patient who had formerly suffered from eczema; he ascribed it to chronic lymphangitis excited by eczema. The blood showed nothing abnormal; it was carefully examined for filaria but none were found.—Mr. R. F. Tobin said that some years ago he met with a case of the disease. The importunity of the patient induced him to tie the femoral artery of the side affected, but the operation, which he performed contrary to his own opinion, did no good.

Dr. J. Magee Finny and Dr. E. J. M. Watson gave details of cases illustrating the use of the X Rays in the Diagnosis of Intra-thoracic Tumours. Dr. Finny claimed for the x rays a great utility in clearing up the doubts which must attend such cases as regards (*a*) the presence of a new growth or an aneurysm, (*b*) the pulsatile or non-pulsatile nature of the tremor, and (*c*) the exact position and dimensions of the tumour. He also submitted skiagrams which Dr. Watson had taken of three cases which occurred in 1901. Case 1 was an example of sarcoma of the right lung which occurred in a woman, aged 30 years, whose illness commenced with hæmoptysis. When admitted under Dr. Finny's care in Sir Patrick Dun's Hospital in February, 1901, the right side of the thorax was apparently full of fluid and was opaque to the x rays, so that no information was at that time afforded. Something more serious than pleural effusion was suspected because the right mamma and the subcutaneous tissue of the right side were thick and œdematous and the veins were varicose with a downward blood-stream. After 72 ounces of serum, clear and free from inflammatory or other morbid products, had been withdrawn, Dr. Watson took the skiagram now exhibited, and it was then evident that a tumour existed in front of, and to the right of, the vertebral column occupying more than three-fourths of the lung space below the level of the fourth rib and extending to within a short distance above the diaphragm. Although the tapping gave relief to the dyspnœa and some of the other symptoms, the solid œdema, the varicosity of the veins, and the other evidences of intra-thoracic pressure did not disappear, but rather increased, causing cyanosis and dysphagia, and the patient died at home four and a half months subsequently in an attack of breathlessness. No necropsy was obtainable. The disease was primary, and, considering the age of the patient, it was presumably sarcomatous and had its origin in the connective tissue of the glands in the posterior mediastinum. Cases 2 and 3 were examples of aneurysm of the aorta occurring in adult males, aged 42 and 54 years respectively; the first was an aneurysm of the arch, the latter was an aneurysm of the descending thoracic aorta. In Case 2 the x rays showed that the sac was much larger than physical examination could determine and extended quite as much to the left as to the right of the middle line. In Case 3 the x rays showed a very distinct shadow in the region of the aorta, above the heart, extending well to the left side, and, more than that, the tumour was seen by the screen to be distinctly pulsatile, enlarging with each systole of the heart. In both cases a modified Tufnell treatment was adopted and iodide of potassium was administered for five to seven weeks and both patients left hospital greatly benefited as regards relief from pain.

Dr. W. S. Haughton read a paper on the Use of the X Rays in Medical Diagnosis. He said that in his opinion x-ray examination in chest cases would eventually come into very general use. Before describing his method of examination he stated that the fluorescent screen was preferable to photography because cardiac movements disturbed the lung a good deal and although respiratory movements could be avoided by very short exposures the heart movements always spoiled the photographic result.—Dr. T. P. C. Kirkpatrick, Dr. Lane Joynt, and the President took part in the subsequent discussions.

---

Hunterian Society.—An ordinary meeting of this society was held on March 12th, Dr. A. L. Galabin being in the chair.—Dr. Galabin delivered a Presidential address on the Annual Variation of Puerperal Fever compared with that of some Allied Diseases.—Dr. R. Hingston Fox read notes of a case of Vaccinia with a Generalised Eruption simulating Small-pox. A vigorous young man, aged 26 years, a student, was vaccinated with glycerinated calf-lymph. Two fellow-students vaccinated at the same time had ordinary vesicles without further symptoms. In the case under notice the vesicles were rather large; the area of redness around was about three inches in diameter. Upon the ninth day of vaccination he felt unwell. On the next day there was more malaise, but only slight, general pain. On the eleventh day he complained of sore spots on his back and kept his bed. The temperature was 102·6° F. and the pulse was 112. He was flushed, with furred tongue but not much prostration; the fauces were very red and swollen but no spots were visible on the palate. There was an eruption of spots at the root of the neck, chiefly about the inner end of the right clavicle, three or four more over both scapular regions, and a few indefinite papules about the nates, the right patella, and on the face. Those about the root of the neck, and especially two or three of those on the back, were quite indistinguishable from the pocks of variola, having a central hard pustule not collapsing on puncture and a red areola. On the next day the temperature was normal and the spots had slightly receded, the little pustules drying up and no fresh ones appearing. After this he quickly became well. On the twenty-fourth day of vaccination the spots were still present, consisting of a small central scab little raised above the surface of the skin and slight areola. The diagnosis presented at first much difficulty. The slight prodromata, the fewness of the spots, and the distribution, entirely avoiding the face, wrists, and ankles, were against small-pox. On the other hand, several of the pocks were exactly like those of variola, and it was thought possible that it might be that disease, greatly modified by the co-existence of active (inebriety) in its manifold forms. The period of time recommended was to be at least 12 months, as shorter periods were not to be relied upon for prolonged cases. During the quinquennial period ending 1884 there was a yearly average of three retreats and 71 patients annually admitted thereto, whereas in 1900 alone there were 20 licensed retreats and 422 patients admitted for treatment. After 20 years' experience this maintained advance was the strongest evidence of utility and sufficient proof that retreats were meeting the requirements of an increasing demand for institution treatment and control of inebriates.—An animated discussion followed in which the President, Dr. A. E. Larking, Mr. W. F. Chambers, Dr. P. G. Lewis, and others took part, and Dr. Norton replied.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held on March 19th, Mr. J. Collier, the President, being in the chair.—Dr. W. Walter showed a Solid Tumour of the Right Ovary removed from a multipara, aged 39 years. The pedicle was fleshy and vascular. When drawing the tumour through the abdominal incision the fingers penetrated the capsule which was friable over a small area where the tumour was soft like putty and of a pink colour. The other ovary was atrophied and there was no ascites. On section the tumour was seen to be of the consistence of a pear, yellowish-white in colour, with a pink streak in the centre. Microscopically the stroma of the ovary was found to be extensively infiltrated with round cells resembling closely in appearance a sarcoma testis, but the arrangement of the cells permitted the possibility of a carcinomatous origin.—Dr. T. P. Cowen and Dr. J. Orr described a case of Syringomyelia with symptoms of Progressive Muscular Atrophy only, without Sensory Symptoms or Spastic Paralysis. The spinal cord was wasted and softened in its upper half. There were two cavities in the grey commissure surrounded by gliomatous tissue extending from the first cervical segment to the upper lumbar segments. The anterior one was the real central canal and was partially obliterated for almost its whole length but with occasional dilatations. The posterior one—a large cavity—had enlarged by gliomatosis and softening so as to invade almost the whole of the grey matter, especially in the mid-cervical and dorsal regions. There were marked ascending and descending degenerations.—Dr. Moore showed two specimens of Unsymmetrical Kidney and he referred to compensatory hypertrophy of the kidney.—Dr. W. M. Smith (Leeds) showed two Ovarian Tumours removed by operation.

# Reviews and Notices of Books.

*Selected Essays and Monographs, chiefly from English Sources* (BRAXTON HICKS, BODINGTON, HODGKIN, PAGET, HUMPHRY, EHLERS). With Obituary Notice of the Society's late Treasurer, Dr. W. Sedgwick Saunders. London: The New Sydenham Society. Vol. clxxiii. 325 pages text, 6 pages Report.

IT is announced in the preface to the present volume that it has been decided during the next five years to spend the funds of the New Sydenham Society almost entirely in the publication of a "Clinical Atlas of Illustrations of Disease," to abstain from undertaking the translation of any large works, and to refrain almost entirely from reprinting the works of English authors. In this volume, which will therefore be for a time at least the last of its kind, there are several monographs which are of interest chiefly from the historical point of view, and amongst these are three papers by Sir James Paget, one by Sir George Humphry, and Dr. Hodgkin's original article which contained the first description of the disease with which his name is associated. The collected papers of Dr. Braxton Hicks are presumably published in this volume chiefly with a view to place on permanent record in a readily accessible form some original work which might otherwise have been scattered abroad. The monographs of Sir James Paget are on Symmetry and Disease, on Disease of the Nipple, and on Osteitis Deformans It is not too much to say that these papers will prove of permanent interest. Sir George Humphry's note is on a case of Unilateral Hypertrophy of the Gums associated with other abnormalities, chiefly hypertrophic and unilateral. This brief article may well serve to show the younger surgeons of to-day the way in which such a paper should be written.

The most interesting of the contents of the volume appear to us to be the reprint of Dr. Bodington's pamphlet on the Cure of Consumption and Dr. Ehlers's History of Danish Lazar-houses in the Middle Ages. George Bodington was born at about the beginning of the last century, was educated at Magdalen College School, Oxford, was apprenticed to a surgeon at the age of 17 years, afterwards became a student at St. Bartholomew's Hospital, took the licence of the Society of Apothecaries in 1825, and immediately went into practice at Birmingham. He afterwards removed to Sutton Coldfield, Warwickshire, devoted most of his life to the treatment of the insane, and took considerable interest in the local affairs of the borough in which he lived. He was endowed with a large measure of common-sense and was a fearless writer. His chief title to fame is to be found in the paper which is contained in the present volume, and is due to the fact that he strongly insisted on the importance of fresh air at a time when the balance of medical opinion was directly opposed to its use and when physicians of the greatest respectability took every available means to keep it from consumptive patients who would have been the most benefited by its inhalation. "One mode of treatment prevailing," says Dr. Bodington, "consists in shutting the patients up in a close room, to exclude as far as possible the atmospheric air, and thus forcing them to breathe over and over again the same foul air contaminated with the diseased effluvia of their own persons." This, he maintained, was a treatment founded on the most erroneous principles, and "more deserving of reprobation than is even the apathetic indifference and desperate hopelessness generally entertained with regard to this disease." He goes on to condemn strongly the exhibition of tartarised antimony—"a fashionable medicine" and "a most destructive one." "Patients seldom long survive the use of this medicine when administered freely if the disease is much advanced unless an antidote to the poison be timely given." Dr. Bodington taught that "the most important remedial agent in the cure of consumption" was the free inhalation of a pure atmosphere—not "the impure air of a close room ...... but the air out of doors, early in the morning." Patients should walk if they could, otherwise "riding or carriage exercise should be employed." Dr. Bodington says that "the surest way in which a successful treatment can be arrived at by the medical man is by the reception under his own roof of the consumptive patient"—if the sanitary conditions of his house happen to be suitable. Special consideration is given to the sleeping-room which should be cool, airy, and properly ventilated. Dr. Bodington's paper did not revolutionise the practice of his time; it probably did not receive the attention it deserved. Its teaching, however, is well in accord with the present "mode."

Dr. Edward Ehlers's article on the Danish Lazar-houses in the Middle Ages contains a very large collection of miscellaneous information derived from various sources. In its present form it gives the reader the sort of pleasure which is to be derived from looking over a number of antiquarian notes in their natural form before they have been finally classified and digested. The article has three illustrations, one showing a Medical Visitation of a Leper (Strasburg, 1535), Satan striking Job with Leprosy (same date), and a Leper with his Rattle, from Franklin's "Vie Privée d'Autrefois, Hygiène," of which the original source is not stated. The title of Dr. Ehlers's article is a little misleading, for less than half of it is devoted to Danish lazar-houses. It is

Wells, and Civil Surgeons Sterne, Bowen, Pickering, Wilkinson, and Buckley have been discharged from hospital to duty.

### THE MEDICAL JOURNAL OF THE ITALIAN NAVY.

The *Annali di Medicina Navale* enters upon its eighth year of existence with a double number, comprising the parts for January and February, 1902, and consisting of 260 pages, rather more than half of which are devoted to reviews. In a prefatory note the editors apologise for the delay which has arisen from unforeseen causes and is by no means attributable to a lack of material. As a matter of fact they receive a continuous influx of important papers from their colleagues, some of whom are fortunate enough to be following university courses in Italy or elsewhere, while others are charged with the care of the sick in the various naval hospitals, with the sanitary superintendence of these and other establishments, with the supervision of the emigration department, and, in fine, with general medical and sanitary duty in different quarters of the world. Having such a wealth of matter there can be no difficulty in conducting the *Annali* in a satisfactory manner, but it is also the intention of the editors to keep their readers well abreast of all scientific progress wherever it may occur. In the present issue the leading article is by Dr. C. M. Belli who discusses the important question of "Bilge-water in Men-of-War" at considerable length and with much erudition. A shorter paper by Dr. Enrico Bindi on Operative Procedure in Cardiac Traumatic Lesions is also of considerable interest, being admirably illustrated.

### SUDDEN DEATHS IN THE RUSSIAN ARMY.

During the quinquennium ending December, 1898, there were 537 cases of sudden death among the soldiers occupying the Warsaw district, 204 of the fatalities being ascribed to disease, 223 to accident, and 110 to suicide. Dr. Scherkin, who is the author of a statistical paper on the subject in the *Voienno Medicinski Journal* for October, 1901, does not mention the exact strength of the troops concerned but merely enumerates the various units as follows: infantry, 57 regiments; Chasseurs, seven corps; garrison infantry, 16 regiments; garrison artillery, six battalions; field artillery, 11 brigades; siege artillery, seven batteries; cavalry, 25 regiments; Cossacks, six regiments; sappers, four battalions; pontoon-trains, two battalions; and railway corps, one battalion—in all 142 units, probably comprising about 125,000 men. Deaths from disease were classified as sudden when less than 24 hours had elapsed after admission to hospital.

### MEMORIAL TO THE LATE SURGEON-GENERAL W. NASH.

The following subscriptions to the above fund have been received since our last notification:—Lieutenant-Colonel E. A. H. Roe, £1 1*s.*; Colonel F. W. Moore, 10*s.*; and Sir J. Fayrer, K.C.S.I., £2 2*s.*, making a total of £23 2*s.*

## SERUM REACTION IN MALIGNANT ENDOCARDITIS.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of March 22nd, p. 817, is a report by Dr. W. Hale White and Mr. W. C. C. Pakes on a case of malignant endocarditis giving the serum reaction (so-called "Widal" reaction). Upon this I should like to offer a few remarks. I know that it is not quite fair to either author or critic to base arguments on an abstract report. Not having heard the paper read I must excuse myself that it is all I have to go upon. The points at issue are of some importance regarding the value of the test. The authors base the title of their paper on the fact that the serum in this case gave a reaction when diluted 1 in 20 with four strains of the typhoid bacillus and with a fifth partially at 1 in 200. Now I would submit that a reaction occurring in a dilution of 1 in 20 will not suffice for the diagnosis of enterica. The dilution is not high enough. This was pointed out some years ago by myself and others. It is, of course, not often that a blood is found which does react in this dilution, but they do occur occasionally, even in normal individuals. In the case of the fifth sample of typhoid bacillus the fact that it reacted partially in a dilution of 1 in 200 to my mind throws some doubt on the identity of the bacillus or its virulence must have been minimal.

I do not gather from the abstract what the time-limit was or whether the reaction was obtained only after the treatment with anti-streptococcus serum had commenced. Since many bloods will agglutinate if given sufficient time and since horse-serum also often spontaneously agglutinates typhoid bacilli in comparatively high dilution I think these are points of importance, especially the latter, since the reaction seems to have appeared only after treatment had been begun. Should any number of cases occur which give a positive reaction with suitable technique in cases *not* enterica the test will be practically valueless. I have not myself in the course of some experience (based on a dilution of a 1 in 33 and 30 minutes' time-limit) seen any *positive* results in cases where enterica, either past or present, or conferred immunity could be definitely excluded. *Negative* results in cases which are clinically thought to be enterica are comparatively common, especially in the early days of the disease; but in view of recent work by various investigators, as well as of some observations which have come under my own notice, I feel certain that the clinical diagnosis in some of these negative cases has not always been correct. I am, Sirs, yours faithfully,

Liverpool, March 24th, 1902. ALBERT S. GRÜNBAUM.

## DRUNKENNESS AND THE ABUSE OF NARCOTICS.

*To the Editors of* THE LANCET.

SIRS,—

"Intemperance, like a roaring flood,
Is sweeping o'er our land;
Its dire effects in tears and blood
Are traced on every hand."

Everybody deplores drunkenness. Everybody admits that something should be done to mitigate the evil. Everybody will not agree about how the mitigation is to be accomplished. Total abstainers desire their way; prohibitionists and local-vetoists desire theirs. Others think that it would be sufficient to restrict the number and hours of public-houses and to abolish all grocers' licences. The latest proposal hereabout is to make the publicans in populous places—in specified areas of Glasgow and Dundee—close at 10 P.M., the same as in country districts. The most pernicious drinking is in the morning, and it would be much better not to allow any alcoholic beverages to be sold before noon.

It is often said that a nation cannot be made sober by legislation: this nation will never be made sober by any other means. The laws of a nation that would be happy and prosperous should be like the unwritten laws of a well-ordered household, giving every facility to all its members to do well but no facilities to do otherwise. When a member of a family betrays a weakness for alcoholic beverages the use of these beverages in that house is either entirely abolished or very much restricted, and if the same restrictions could be kept up when that weak member was outside the house he would never become, as too often happens, a drunkard and a disgrace to the family. The other members of the family may feel these restrictions somewhat irksome; but they cheerfully acquiesce in the new arrangements for the sake of their weaker member. In the greater family—the nation—it is well enough known there are many weak members, and if restrictions be put upon the procuring of alcoholic beverages which may be somewhat irksome to many, they should not complain for the sake of the weaker members. The total abolition of drunkenness might be quickly accomplished by the Government undertaking the making, importing, storing, and distributing of all alcoholic beverage and, instead of granting licences to publicans to sell these to Tom, Dick, and Harry in indefinite quantities, granting descriptive licences to whoever desires to use these luxuries, with coupons attached for each day's allowance to be given up when obtained. A small sum to be paid for the licence which may be valid for a week, month, or year, and the drink to be paid for when obtained. The day's allowance for an adult should not be more than five fluid ounces of proof spirit, or the alcoholic equivalent of that in any other beverage; and the licence coupons could be so arranged that the day's allowance could be obtained at two, three, or four times. Special licences could be granted as now for special occasions and to responsible persons who would guarantee that there would be no abuse of the beverages; and as all the alcoholic drinking of the country would be under the eye of the Government any abuse of these licences or privileges could soon be put down.

About 30 years ago a circular was sent to all the medical men in this district "asking them to refrain as much as possible from prescribing alcohol in any form." My reply was that I prescribed castor oil when required and that I expected when the patients got better they would cease taking it, and that I expected that if I prescribed any alcohol the patients would do the same. I received another notice that many drunkards alleged that the beginning of their bad habits took place when they were under medical treatment, which may be quite true in some cases. Certainly it is perfectly true that many women begin to use alcohol in some form for painful menstruation and during puerperal weakness, and many others have begun to use narcotics by a medical man being either too busy or too lazy to write a prescription, telling his patients to go into the nearest druggist's and purchase a narcotic and take so much of it. Much drunkenness and narcotic-consuming might be prevented by medical men always and only administering alcohol and narcotics medicated in a prescription, not to be repeated unless sanctioned by the prescriber.

Thanking you in anticipation of your finding room in your valuable journal for the above, and hoping that other members of our profession may be induced to state their opinions how best to combat these evils,

I am, Sirs, yours faithfully,

Paisley, March 18th, 1902. J. B. HUNTER.

## A NATIVE REMEDY FOR BLACKWATER FEVER.

*To the Editors of* THE LANCET.

SIRS,—I have read with great interest the notes by Dr. D. R. O'Sullivan-Beare in THE LANCET of Feb. 1st, p. 282, on the native remedy for blackwater fever and I should like to offer a few suggestions on this most important subject.

Before dealing with the question of the remedy there are several points raised in this paper as to the nature of blackwater fever which call for some comment. In the five cases quoted the patients had either never tasted quinine or at least had not taken it for two months previously, so that this adds one more to the many facts which militate against the dangerous doctrine that quinine is the cause of blackwater fever which has prejudiced large numbers against the use of quinine. I most emphatically differ from Dr. O'Sullivan-Beare in his view that blackwater fever is not a form of malarial fever, and I consider that "the test of practical experiment" is in favour of the use of quinine in its treatment. I believe it to be an assumption which has not been proved that the hæmoglobinuria is caused by a toxin rather than by the parasite itself, and the idea which is suggested that nephritis is set up in *ordinary* cases is in my opinion an erroneous one, the albumin present being due to the presence of hæmoglobin. The mention of two cases of blackwater fever occurring among negroes is interesting, as I do not think this is common, and it will be still more important if the information can be borne out which Dr. O'Sullivan-Beare has obtained concerning some tribes in the interior, "amongst whom blackwater fever would appear to be endemic"; but may not this be hæmaturia due to bilharzia hæmatobia?

Having delivered myself of these criticisms I desire to thank your correspondent most heartily for the interesting particulars which he has given us concerning this native remedy, for although I do not agree with his estimate of the value of quinine in this disease there can be no question that we are in need of other remedies, and I think that after the testimony we have received *Cassia Beareana* should receive a full trial. As to its mode of action and the reason for its usefulness a few remarks may not be out of place. The most important points in the treatment of blackwater fever, apart from any specific malarial treatment, are to maintain the flow of the urine and to deal with the vomiting which is often a dangerous feature of the malady, making it difficult to administer either food or medicine and weakening the patient. It seems to be a point in the prescription of this medicine to give it with a great deal of fluid, and probably this assists in promoting free diuresis, even if the drug itself is not a diuretic. But what interests me more is the influence which it appears to have upon vomiting. In the cases mentioned vomiting seems to have been a prominent symptom and the medicine seems to have relieved it. Perhaps even more striking than the effect of the remedy upon blackwater fever is the result obtained in so-called bilious remittent fever. I have sometimes wondered whether the number of cases classed under this head are all of them malarial; at all events the trouble here is usually vomiting and this the medicine seems to relieve. If this is so, the drug may be useful in other cases where vomiting is a troublesome symptom and it is to be hoped that all who use it will note carefully the effects produced, so that we may not be acting in the dark in prescribing the remedy.

I am, Sirs, yours faithfully,

CHARLES F. HARFORD-BATTERSBY.

Livingstone College, Leyton, E., March 24th, 1902.

## VAGARIES OF VACCINIA.

*To the Editors of* THE LANCET.

SIRS,—From personal experience of the vagaries of vaccinia I am intensely interested in the clinical note sent you by Dr. J. W. Washbourn, published in THE LANCET of March 8th, p. 664. It is within the recollection of many of your readers that when the Local Government Board first introduced the glycerinated calf-lymph it was found to be very irregular and uncertain in action. A not uncommon experience was to make four careful scarifications, insert the glycerinated calf-lymph from the same tube in each, and then to find quite a variety of vesicles, papules, blebs, and minute vascular spots, these last resembling small nævi, none of them coming to maturity and disappearing without leaving a cicatrix; one class of immature vesicles left a slight scar more like staining of the skin than a scar.

I have notes of a case almost identical with the one recorded by Dr. Washbourn. In March, 1899, I vaccinated a child, a female, aged two years, in four places. Two of the scarifications developed into mature vesicles leaving well-marked cicatrices; the other two were simple blebs, with no areola; the serous fluid was re-absorbed, the vesicles shrank and never scabbed. The mark left was more like a stain than a cicatrix. After a lapse of nine months the mother complained that whenever the child had a cold the vaccination spots came back. At first I treated this piece of curious information as purely mythical—on a par with many of the funny things said about vaccination. However, to please the mother I asked her to let me see the child's arm when she had the "spots" on again. This she did in the course of a few weeks, when, to my surprise, at the site of the *imperfect vesicles only* the superficial layer of the epithelium was raised in the form of two or three small vesicles resembling exactly a group of herpes; be it noted there were none in the cicatrices left by the mature vesicles. I saw them two days after the child scratched them; they were red at the base and covered by a scab. To prevent further scratching the arm was dressed; the sores soon healed and left *no scars.* Now, it may be due to over-dulness, but it requires a stretch of the imagination to fancy that in this case the vaccinal virus in the original lymph was of two kinds—one active, producing satisfactory results; the other inert, lying dormant for nine months and then by the aid of a cold or, as in Dr. Washbourn's case, scarlatinal infection developing its latent powers in producing good results. Or shall we put it this way—the more or less inert lymph having exhausted its strength in its first abortive effort, by a further period of rest in the living tissue acquired sufficient vitality when reinforced by scarlet fever to produce true vesicles.

With your permission, Sirs, I should like to ask so great an authority as Dr. Washbourn one or two questions. His patient was vaccinated in four places, "only *one* of which took and that very slightly," yet we are informed further on that Mr. Percy Rose found four spots on the left arm at the usual site of vaccination. Query, were there cicatrices "at the usual sites of vaccination"? Again, and more important, did the four spots, "exactly like mild vaccination at about the seventh day," leave cicatrices behind them like genuine cases of primary vaccination? Is it not generally the case that the concurrence of scarlet fever, whooping-cough, and measles modifies rather than accentuates the vaccinal process? My own interpretation of the phenomenon was that it was either herpes or due to some other irritant producing dilatation of the capillaries of the cutis causing the superficial layers of the epithelium to be raised from the deeper in the form of a bleb.

I am, Sirs, yours faithfully,
March 24th, 1902. J. MACKENZIE.

## BEEF-WORM IN THE ORBITAL CAVITY.

*To the Editors of* THE LANCET.

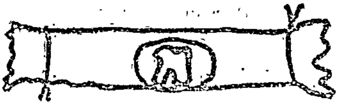
SIRS,—In connexion with my article "Beef-worm in the Orbital Cavity," published in THE LANCET of Jan. 4th, 1902, p. 19, I have received the following suggestions from Mr. Ernest Austen who has charge of the collections of diptera in the British Museum. The so-called beef-worm, he thinks, is the larva of a species of dermatobia, probably *Dermatobia cyaniventris*, a dipterous fly belonging to the family œstridæ. I stated that the egg had been laid by the parent fly *beneath* the human skin or mucous membrane, but Mr. Austen suggests—and no doubt rightly—that the egg was laid *upon* the skin and that the larva, on hatching, burrowed beneath the surface in the subcutaneous tissue, which would account quite satisfactorily for the extraordinary position in which it was found. I stated that in the full-grown worm the bristles encircling the middle two-thirds of the body attained a length of half an inch. This statement had never been verified by personal experience, as the longest bristles I have seen on the creature have never exceeded one-twelfth of an inch, but I considered my authority reliable. Mr. Austen, however, informs me that the bristles *never* reach a length of half an inch in *any* dipterous larva.

I am, Sirs, yours faithfully,
Corozal, British Honduras, March 4th, 1902. THOMAS GANN.

## INTESTINAL OBSTRUCTION CAUSED BY A TOOTH.

*To the Editors of* THE LANCET.

SIRS,—On Sunday, Feb. 9th, I was called to see a dentist in this neighbourhood and on arrival found him dead. He was taken suddenly ill the night before with colic but I was not sent for till too late. I performed a necropsy and found all the organs normal. However, about midway between the duodenum and large intestine I found an obstruction in the shape of a hard foreign body. I removed the piece of intestine and on examination found a molar tooth encysted in a membrane which had become attached to the inner wall of the gut thus. It was a natural tooth and had evidently been there for a long period.



I am, Sirs, yours faithfully,
GODFREY WARNES.
Great College-street, N.W., March 23rd, 1902.

## CANCER IN INDIA AND IN CHINA.

*To the Editors of* THE LANCET.

SIRS,—In THE LANCET of to-day (March 22nd) Lieutenant-Colonel Maitland, I.M.S., writes that, "To say, as Mr. Keetley does, that I [i.e., Lieutenant-Colonel Maitland] alone am responsible for all the medical and surgical wants of 30,000,000 Hindoos in Southern India is as absurd as it would be to say that Mr. Keetley was responsible for the whole population of London." This seems to be Lieutenant-Colonel Maitland's *idea of a fair description* of the following sentence in my letter in THE LANCET of Jan. 18th (p. 193): "Captain Donovan says that Colonel Maitland speaks for the Madras General Hospital where cases from all over the Madras Presidency come for operation." I see nothing absurd in this statement of Captain Donovan.

Every London surgeon who once gets "known" does draw his cases from among the 5,000,000 of Londoners and from far beyond; but his position differs from Lieutenant-Colonel Maitland's in this: that there are 50 other surgeons as well known as himself practising in the same city with the Londoner, while the professor of surgery's position is unique at Madras. Therefore, the fact that the latter "almost always has one or two" Hindoo patients suffering from cancer is no proof of their suffering from it as much as Europeans.

I am greatly obliged to Lieutenant-Colonel George Ranking, I.M.S., for his valuable letter.

I am, Sirs, yours faithfully,
Grosvenor-street, W., March 22nd, 1902. C. B. KEETLEY.

## LOCAL OPTION IN VACCINATION.

*To the Editors of* THE LANCET.

SIRS,—I see that the town council of Hastings on March 21st passed a resolution to request Parliament in this session to abolish the conscientious objector clause and also to make revaccination compulsory. Seeing the difficulty of legislation now would it not be well to allow towns or counties who prefer it, say by a two-thirds majority, to adopt such regulations at once? Surely a short Act to that effect might be got through Parliament. The result of a few years' experience would then be convincing.

I am, Sirs, yours faithfully,
GEORGE HENDERSON, M.D., F.L.S.
Bushey, March 22nd, 1902.

## DIPHTHERIA OF THE CONJUNCTIVA.

*To the Editors of* THE LANCET.

SIRS,—One or two small errors have crept into the report published in THE LANCET of March 22nd, p. 818, of a paper on Diphtheria of the Conjunctiva read before the Ophthalmological Society on March 14th. The report represents me as insisting upon the practical value of an immediate examination of "smears" of the discharge, "stained in methylcosine, and the acid reaction of gelatin cultures." What I actually did was to insist upon the value attaching to the staining of cover-glass preparations by Neisser's plan and to the acid reaction of bouillon cultures.

I am, Sirs, yours faithfully,
Welbeck-street, W., March 23rd, 1902. SYDNEY STEPHENSON.

## THE DIPLOMA OF THE SPECTACLE-MAKERS' COMPANY.

*To the Editors of* THE LANCET.

SIRS,—Sir W. Hart Dyke's letter in THE LANCET of March 15th, p. 774, does not meet the case. He says the Company "do not examine in sight-testing." This is evading the question, as the greater part of the examination deals with visual optics and spectacle-fitting, and the Company's official instructor is a gentleman who teaches visual optics only; his printed circulars and advertisements are issued *by the Company* with the particulars and syllabus of the examination, and in one of these circulars he undertakes for a substantial fee to coach for the examination, partly by correspondence and partly by personal tuition at a class held in London during the two weeks immediately preceding the examination. In fact, the worshipful Company provides the examination for a substantial fee and thoughtfully circulates the advertisements of its official instructor who will for another substantial fee endeavour to cram sufficient information into the competitor to enable him to pass, and further thoughtfully provides that if the candidate cannot pass it all at once he may do so by *instalments* at successive examinations.

I am not raising the question as to whether opticians should or should not test sight but I do say that the intention of the original optical committee is not being carried out, that the present methods are calculated to do serious harm, because, though the examination is no proof of anything beyond the fact that the diploma holder possesses a certain amount of optical knowledge, the diplomas are being used for the purpose of inducing the public to believe that they have been granted for proficiency in knowledge particularly connected with the fitting and adapting of spectacles to correct defective eyesight and are used for advertising purposes to draw trade in the shape of the sale of spectacles. This is shown by the fact that some of the holders attach the letters F.S.M.O. to their names in their business advertisements, presumably to imply a professional qualification and also advertise themselves as "qualified by examination." Many of these men have scarcely any practical knowledge of the trade at all and do not even profess to understand anything but spectacles.

I may mention that I and eight of my assistants have passed this examination but refrain from making any public use of the fact.

I am, Sirs, yours faithfully,
JAMES AITCHISON,
Citizen and Spectaclemaker; Member of the Original Optical Committee of the Worshipful Company of Spectaclemakers.
Strand, W.C., March 18th, 1902.

## SIR JAMES PAGET'S LECTURES.

*To the Editors of* THE LANCET.

SIRS,—Old students of Sir James Paget and the many who enjoy and profit by his few preserved lectures may be glad to be directed to your first volume for 1869. There they will find three lectures which have never been republished as well as that on the Treatment of Carbuncle which is included in the volume edited by Mr. Howard Marsh. The other lectures were on "Diseased Joints of the Foot," Jan. 30th; "Treatment of Fracture," Feb. 27th; and "Aneurysm of the Femoral Artery," April 7th and 24th. The last is of special interest. As the headings show, they were all reported for THE LANCET at the request of the Editor, being revised by Sir James Paget. To THE LANCET belongs the credit of their preservation. This is a greater service than it might seem because they are perhaps the only hospital lectures of Sir James Paget preserved as delivered. He went through the reports but hardly altered a sentence. The lectures were given without a note and present perfectly his extempore style.

I am, Sirs, yours faithfully,
March 25th, 1902. THE REPORTER OF THE LECTURES.

## NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

*Plague Riot in Patiala.—Further Increase of the Epidemic.—Samaritan Funds for Indian Hospitals.—Cholera Inoculations.—Researches in Malaria.*

ON Feb. 19th a somewhat serious disturbance took place in Patiala which is said to have been occasioned by the compulsory segregation of two cases of plague. Major H. Hendley, I.M.S., medical adviser to the State, and Dr. Nathu Mau, the civil surgeon, were attacked by a large mob with sticks and bricks and in consequence of being wounded had to take refuge in the branch dispensary. This was then wrecked and set fire to but the troops arrived in time and the officers were able to effect their escape. The plague camp near the railway-station was also set on fire. According to another account Major Hendley was fastened down by a door, was pelted, and was then carried off and thrust into a mass of filth. He was wounded in nine places—most seriously on the head and on the right leg. These disturbances are not common now but their recurrence serves to show that the dangers to which plague workers are subject are very real.

The plague mortality for the whole of India has again increased. During the past week there have been 14,946 deaths, as against 12,695 for the previous seven days. There were 5922 deaths in the Punjab (an increase of 1809), 4373 in the Bombay Presidency (an increase of 543), 1351 in the North-West Provinces, and 863 in Bengal (an increase of 125). In Bombay city and in Calcutta the disease is growing apace. Bombay had a plague mortality of 701, the general mortality being 1635, equal to a rate of over 105 per mille. Calcutta had 176 plague deaths, an increase of 56, and later figures show a very rapid development. Karachi records 47 deaths, the Madras Presidency 543, Mysore State 507, and Kashmir 317. The old idea that plague is favoured by cold weather is not quite extinct but the continued development with a rising temperature in such places as Bombay and Calcutta ought to correct this fallacy. During the corresponding week of last year there were only 6307 deaths, so that the present serious increase of the disease should be noted.

There are not many hospitals in India which have Samaritan funds, so that the recent gift of Rs. 10,000 by Messrs. Ralli Brothers to the Medical College and Mayo Hospitals in Calcutta is particularly happy. It is intended to be used for clothing and the distribution of small sums for temporary assistance to poor native convalescents—Hindoos, Mahomedans, and Parsees.

Some interesting observations have been made by Major Buchanan and Captain Lamb on the effects of cholera inoculations which may be thus summarised: (1) a preliminary injection of a dead vaccine a few days before the living material is inoculated has the effect of increasing the subsequent constitutional disturbance (the larger the dose of the former the greater the subsequent reaction); (2) a slight increase in the amount of living material greatly increases the constitutional disturbance; and (3) a previous attack of cholera (within one month) decidedly lessens the reaction of a "living" inoculation. The chief inoculations for cholera are now at Goalundo, where the coolies for the tea-gardens pass through, but the returns for cholera are optional on the employers so that the information available is scanty.

Other interesting observations which are shortly to be published refer to researches on malaria fevers by the commissioners. The amount of infection of children is a trustworthy index of the general prevalence of malaria and the "endemic index" is determined by the proportion of children and of anopheles found to be infected. What is true for Africa seems to be true also for India. The endemic index was found to range very widely, from *nil* in Calcutta to 72 in the Duars. In Calcutta not one of the children examined had parasites and not one of the anopheletes dissected was infected. The commissioners, however, recognise malarial disease accompanied by parasites and a form without it. The latter is common in Calcutta, is grave in type, and passes into a true malarial cachexia with a large increase in the mononuclear leucocytes. The actual number of anopheletes present in a district is no criterion of the prevalence of malaria. In the Duars anopheletes are comparatively difficult to capture. All species of anopheletes are evidently not equally dangerous and it is thought that anopheles Rosii, a very prevalent species, is hostile or immune to the parasite. Other observations made are that while in the cold weather zygotes would not develop beyond a certain stage they progressed to sporozoites when the infected mosquitoes were warmed by means of an incubator.

Feb. 28th.

## MAIDSTONE AFTER THE EPIDEMIC.

(BY OUR SPECIAL SANITARY COMMISSIONER.)

*(Concluded from p. 701.)*

*The Diphtheria Epidemic.—The Good Effect of Sewer Ventilating Shafts.—The Sewage Disposal and Drainage Schemes.—Other Measures.—Dangerous Street Hydrants.*

WHEN insisting on the necessity of looking to the sewers and domestic drainage of Maidstone, instead of considering only the water-supply, it was pointed out that typhoid fever was not the only disease that seriously menaced the health of the town. Indeed, except for the great typhoid fever epidemic of 1897, diphtheria was doing more damage. During the six years previous to this epidemic there had been 498 cases of diphtheria notified and only 116 cases of typhoid fever. Then when, in 1897, typhoid fever assumed an epidemic form diphtheria did the same, but the typhoid fever epidemic exhausted itself in a few weeks while the diphtheria epidemic lasted three years. There were 211 cases notified in 1897; this increased to 240 in 1898, to 213 in 1899, and ceased only in 1900, when, however, there were still 50 cases. During these three years there were only 35, 23, and 28 cases of typhoid fever respectively. If we take the 10 years from 1891 to 1900 there were in all 2082 cases of typhoid fever notified, and this includes the great epidemic. But though there has been no such great epidemic of diphtheria it will be found that during these same 10 years no less than 1212 cases of that disease were notified. Consequently, if something is not done to check the prevalence of diphtheria it is possible that in the course of years the cases of diphtheria will exceed in number even those of typhoid fever. This danger is so serious that the Local Government Board held an inquiry on the subject in 1899. It was then shown that the schools had served as a focus for the spread of the disease and that when the schools were closed by order and disinfected or adjourned for the holidays the prevalence of the disease abated.

Apart from the closing and disinfecting of schools Dr. Charles Pye Oliver, the present medical officer of health, attributes the gratifying reduction in the number of cases of diphtheria notified during the year 1900 to the construction of a number of ventilating shafts in connexion with the main sewers and to the more general and more efficient flushing of the house drains. As a consequence there has been, he states, a marked decrease in the number of complaints received concerning the offensive odours that used to issue from the street manholes. As already mentioned, four ventilating shafts were constructed in 1897. There were three more erected in 1898 and two in 1899. This was altogether insufficient, but there had been so much talk about the contamination of the water as the cause of disease that the authorities did not yet fully realise the absolute necessity of ample ventilation for the sewers. The fact, previously mentioned, that in the two years following upon the typhoid fever epidemic improvements in domestic drainage had been effected in 7776 cases, while this had been done in only 2794 cases during the previous two years, shows that the importance of this phase of sanitation had been appreciated. It was also understood that more sewers and better sewers had to be built, for the length of new pipes laid amounted to 37,714 feet during the two years following upon the epidemic; this contrasts favourably with the 9250 feet laid in the two previous years. But it does not seem to have been fully realised that though the construction and condition of both private drains and public sewers may be improved, still sewer air will force itself upon the population if the sewers are not efficiently ventilated. This danger is greatest at the high levels, and sewers going down a steep incline are apt to become ventilating shafts for the sewers which they join at a lower level. So long as the air can travel upwards it will do so in a straight line and without seeking side issues. But when stopped suddenly at the top end of the sewer the air will then expand and seek an issue at the nearest point. The pressure may be so great that the sewer air can then force its way even through a well-constructed syphon-trap and thus enter the houses that are on the higher levels. This may explain why by far the greater number—indeed, nearly all—the cases of typhoid fever occurred among those who lived 100 feet or more above the main collectors. Now, at last, this fact has been appreciated and during the year 1900 16 new ventilating shafts have been introduced at the termination or summit of the sewers, and thereupon the epidemic of diphtheria ceased. The figures for the year 1901 have not yet been published, but I am told that seven or eight more ventilating shafts were erected last year. Diphtheria still maintained its hold on the town and there were 82 cases notified in 1901; but this gives an annual average of 66·5 cases for the two years following upon the erection of numerous street sewer ventilators as opposed to an annual average of 221·3 cases during the three years preceding this improvement in sewer ventilation. Of course, this incident taken by itself does not suffice to prove that inefficient sewer ventilation was the one cause of the widespread prevalence of diphtheria and of typhoid fever, but doubtless it contributed to render the population more susceptible. There is good reason to believe that diphtheria especially was spread by personal contact at the schools, where, for instance, some children drank by putting their mouths to the same tap instead of using glasses. Nevertheless, it is obvious that means must be taken to prevent people breathing the air that comes from sewers, especially when, as is the case at Maidstone, these sewers are not all self-cleansing.

The question now arises as to what still remains to be done so that Maidstone shall no longer be exposed to the risk of yet another great epidemic. The two most difficult, because they are the most expensive, reforms needed relate to the disposal of its sewage and the reconstruction of its main collecting sewers so that they shall be self-cleansing. The wisest and the cheapest course would be to unite the two questions and to make the one scheme serve both purposes. Unfortunately, the condition of the sewers at present holds quite a secondary position. The inquiries made and the reports published deal mainly with the disposal of the sewage rather than with the sewers themselves. The first report was made by the borough surveyor, Mr. Bunting, and by Mr. W. J. Dibdin and was presented to the town council in October, 1900 This report estimates the flow of sewage at 30 gallons per head, or 1,020,000 gallons per day, and states that the sewage is sometimes of an exceptionally bad quality in consequence of the admixture of refuse from manufactories. In the course of July, 1897, two bacteria beds, a coarse and a fine bed, were constructed for experimental purposes. They had been working satisfactorily for two years. The solid matter held in solution was completely removed. What was oxidisable in the sewage was extracted to the extent of 69 per cent., and the nitrogenous matter, as measured by albuminoid ammonia, to the extent of 75 per cent. The effluents steadily improved in quality when kept either in open or closed bottles; this, it is claimed, proves conclusively that under no circumstances could they injuriously affect the condition of any stream into which they might be discharged. The land actually disposable for the treatment of sewage amounts to nine and a half acres. According to the Local Government Board regulation, for a population such as that of Maidstone there should be at least 20 acres and the greater portion of the nine and a half acres available is unsuitable for the purpose. Therefore a new site must be secured. The first likely site is near at hand, but it could not be reached without pumping the sewage up to a height of 80 feet. The second site proposed would involve the extension of the outfall to a distance of 633 yards, and then what is qualified as very suitable land would be reached below Allington lock. In this case pumping is also necessary, but only to a height of 25 feet. There is, however, a serious objection. The water company has its pumping-station on the north side of the river Medway immediately opposite this area and has sunk a well near its engines. Then there is residential property in the neighbourhood and it is anticipated that the owners would raise objections. Finally, this land is occasionally flooded. A third outfall is suggested at Millhall and New Hythe, where the land would be cheaper, but it would be necessary to obtain a leave of way from the present outfall at Allington Lock and to pump up the sewage 25 feet. The beds might be cheaper, as they could be sunk in the ground and thus would save the cost of sustaining walls. It will be seen that all these schemes are subject to serious objections, and under these circumstances it was only natural to seek further advice. Therefore Mr. James Mansergh was selected to give an expert report on the question and this second report was published in September, 1901. It also presents a confusing variety of schemes, and there is no agreement as to the principle to be adopted. Shall the sewage be purified by land irrigation? shall such irrigation be preceded by bacterial treatment? or will the bacterial treatment alone suffice? Naturally the last proposal would be preferred if the Local Government Board gave its consent. In that case a much smaller site would suffice. The beds, four feet deep, would cover 7·494 acres, with an extra 1·264 acres for storm water, making a total of 8·758 acres. Then, according to the Local Government Board requirements, there ought to be 17 acres more for irrigation with the effluent. If, however, the bacterial treatment was absolutely perfect there would be no need for the 17 acres. Mr. James Mansergh argues that the proximity of tidal waters and the character of the sewage renders Maidstone a typical place for the application of the bacterial method. Otherwise the only really suitable site is at New Hythe or Lansford, and this is the farthest from the town and the most expensive. Here the outfall into the Medway would be considerably below and beyond the Forstal Well and the waterworks.

Without, however, attempting to give any definite opinion as to the respective merits of these different sites I am more concerned in urging the necessity of diverting the greater part of the sewage from the main collectors that follow the course of the river and are not self-cleansing. The schemes mentioned involve the necessity of pumping the sewage up to reach the site selected. Obviously, it would be preferable to construct a main intercepting collector at a higher level which would bring the sewage by gravitation to the site secured. The sewage of the small portion of the town situated below this high-level collector might continue to flow into the existing main collectors; but perhaps the amount of this sewage would be so reduced that pipe sewers placed inside the main collector would suffice to carry it away, and their cleanliness might be more easily maintained. The larger sewer could be used for rain-water only. In other words, the separate system might be adopted for the lower levels, and the amount of the sewage that would have to be pumped up would thus be greatly reduced and an economy would be effected. The point is to cut in two the long branch sewers which, going down from the highest latitudes to the river bank, act as ventilating shafts to the big collector built at the water side. The high-level intercepting collector, being built on high ground, could be given a sufficient fall to be self-cleansing. Thus the adoption of a new system for the disposal of the sewage should be made to coincide with the introduction of a better system for the drainage of the whole of the town. This would entail a greater outlay, but it is always cheaper in the long run to do what has to be done once for all and thoroughly.

By the side of vast schemes of this description, which are of no productive value, there is a good opening for smaller enterprises at Maidstone, such as the building of a municipal common lodging-house and artisans' cottages which might be made a source of municipal revenue. Also, there are many complaints as to the collection of household refuse and this likewise might be undertaken by the municipality and done more efficaciously. It should be possible in an agricultural centre like Maidstone to sell some portion of the refuse at a remunerative price. Then there are private courts and alleys where the scavenging is very inefficient. As these are not public thoroughfares it is not the business of the municipality to keep them clean and in such places decaying organic matter is apt to accumulate. The owners should see to its removal, but the fact remains that they neglect to do so; and as in such places gratuities are not forthcoming the refuse collectors are also liable to be forgetful. But if the refuse was collected by municipal servants and was a source of municipal revenue such negligence would be less likely to occur. There is yet another point which is a matter of detail but might lead to serious consequences if neglected. The system for closing the street hydrants cannot be qualified otherwise than as dangerous. In the vertical pipe that rises from the main to reach the surface of the street there is an enlargement forming a little chamber big enough to hold a gallon of water. Here is placed a vulcanite ball which is forced up to close the upper aperture by the pressure from the main below. To open the hydrant a key is introduced which presses this ball out of place and then the water surges up into the street. This is all very well so long as the main is full and the pressure is strong enough to hold up the ball in its place. But the effecting of repairs, or intermittent supply during dry seasons, or other causes may reduce this pressure, and then the ball falls from its position. Dirt and water from the street can then enter the space where the ball is kept and thence can reach the main to mix with the water which the inhabitants drink. There are 279 such hydrants in Maidstone, and it is not to be expected that in all cases they should invariably remain in proper working order. This system was adopted some 40 years ago. It was then considered ingenious, but now it is quite obsolete and a safer apparatus should be employed. The medical officer of health in his last report describes a specimen of water which contained nematodes four inches long. He suggests that in its embryo stage the nematode burrows into certain insect larvæ which are swallowed by water-beetles and other aquatic insects. Here it becomes encysted and is discharged by the beetle into the water, where it develops into young and perfect nematodes. The pathogenic germ might, with equal facility, reach the water-supply through these defective hydrants. Seeing how much work has now been accomplished to improve the general sanitary condition of Maidstone it is not too much to hope that the remaining sanitary defects will soon be swept away. In this manner will the great typhoid fever epidemic have proved itself a blessing in disguise.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Jubilee of Owens College, Manchester.*

THE Prince and Princess of Wales visited Manchester on March 12th in connexion with the jubilee of Owens College and the opening of Whitworth Hall, the latest addition to the collegiate buildings. They arrived at the Victoria station at 10.50 A.M., accompanied by their host and hostess, the Earl and Countess of Derby, and were met at the station by the Lord Mayor and other officers of the corporation of Manchester. They then proceeded to the college, where the Duke of Devonshire, the President of the college, and Principal Alfred Hopkinson received their Royal Highnesses. After a reception by the governors and senate in the Christie Library, a procession was formed which included the teaching staff and lecturers. Several distinguished Members of Parliament, notable professors, and eminent ecclesiastics were present, including Earl Spencer, Chancellor of the Victoria University. Thus escorted into the hall the Prince and Princess took their seats on the right of the Duke of Devonshire, the audience rising and singing "God Save the King." The Duke of Devonshire thanked the Prince and Princess for their presence at the celebrations and said that the idea of the founder was to provide in that great centre a university to supply higher education in such branches of learning and science as were usually taught in English universities. It was laid down as a fundamental and immutable rule that the governors, teachers, and students should be subject to no religious tests. The address of welcome from the college authorities was then read by the Principal. Afterwards Alderman Thompson presented to His Royal Highness on behalf of the council a gold key of the hall. The Prince expressed the pleasure of himself and the Princess at being there that day to join in the celebrations and to open the beautiful hall. He regretted the absence of the architect (Mr. Alfred Waterhouse) and of Dr. A. W. Ward and Sir Henry Roscoe through illness. He said also that a college which after five years of its existence was reduced to 33 students and yet could persevere in the path which had been originally marked out, and which could now boast of 32 professors and over 1000 students, had indeed earned a just right to celebrate with pride and satisfaction its first jubilee. He also made sympathetic reference to the names of Owens, Beyer, Christie, Whitworth, and other benefactors of the college, and paid compliments to the great teachers and students who had by their genius and force of intellect maintained in the college a high standard of learning, and added that the presence there that day of the governing body and the representatives of the municipalities of Manchester and the neighbouring towns should serve to strengthen the mutual sympathy and guide the college in its work. He called attention to the special effort recently made to raise a fund to pay the amount of the indebtedness of the college, which was very considerable, and to provide against an annual deficit, and said that the fund had now reached £100,000, which, however, was only enough to carry on the extended work of the college without making additions to the staff and appliances which it was desirable should be made. He was sure that Manchester men would not allow this institution in any way to suffer from want of funds. He then declared the Whitworth Hall open. The meeting was addressed by Sir R. C. Jebb who took the place of Dr. Ward as "representative of literature" and by Professor Rücker as "representative of science." Thanks for their addresses were voted on the motion of Sir F. Adam. The Prince subsequently at the town hall received an address of welcome from the corporation of Manchester and made a suitable reply; he said that had it been practicable to include in that day's proceedings the opening of the new school of technology he would gladly have taken part in that ceremony. The Prince and Princess, with about 300 other guests, were entertained to luncheon in the principal room of the hall. The Prince referred to the recent tour of the Princess and himself and also said that he was sure that they were all happy to see present amongst them so many distinguished representatives of foreign and colonial universities, who had come to take part in the proceedings. On the way to the Victoria station the Royal procession halted at the west porch of the cathedral for the unveiling of a statue of Queen Victoria, the work and gift of Princess Louise, Duchess of Argyll. The Royal departure for Knowsley took place a few minutes after 4 P.M. Several of the tradespeople who occupy premises along the line of the route of the Royal procession offered to give to the hospitals the money received from letting their windows to sight-seers. The Lord Mayor approved the idea and mentioned that as regards subscriptions Manchester compared unfavourably with other large cities. It is to be hoped that the hospitals will benefit considerably by this generous offer.

### *Manchester and Salford Sanitary Association: Jubilee Conference.*

The committee of this association has decided to hold a Conference on Sanitary Reform in commemoration of the fiftieth anniversary of the formation of the association. This conference will take place in the Town Hall, Manchester, on April 24th and 25th next. On April 24th the Bishop of Manchester, who is the President of the association and of the general conference committee, will deliver an inaugural address. Dr. Arthur Ransome, F.R.S., will then relate the interesting history of the Manchester and Salford Sanitary Association, and Sir James Crichton Browne, F.R.S., will follow with an address on Light and Sanitation. On April 25th Mrs. H. J. Tennant will speak on Women's Work in Sanitary Reform; Dr. Arthur Newsholme of Brighton will discourse on Vital Statistics and their Relation to Sanitary Reform; Mr. T. C. Horsfall, a local authority, will read a paper on the Housing Question; Sir William H. Broadbent will give an address on the Prevention of Tuberculosis; Dr. A. Bostock Hill of Birmingham will deal with the Relationship of Voluntary Effort to Constituted Authority in promoting Sanitary Reform; the Earl of Meath will speak on Physical Training; and Dr. J. Niven of Manchester will deal with the Economics of Health. Amongst others who will preside at meetings are Professor J. Dixon Mann, M.D. (the present chairman of the association), Sir William H. Houldsworth, Bart., M.P., Mrs. Moorhouse, Dr. Henry Simpson (a former chairman of the committee), Alderman Walton Smith, J.P. (chairman of the Sanitary Committee, Manchester), Mr. W. J. Crossley, J.P., C.C., Mr. A. Hopkinson, K.C., (Principal of Owens College), the Mayor of Salford, Sir J. T. Hibbert, K.C.B., and Councillor W. Huddart (chairman of the Salford Health Committee). Many municipalities, urban district councils, and other public bodies have appointed delegates or intimated that they will be otherwise represented. All local institutions having aims in common with the association are represented on the conference committee. The proceedings of the conference will be eventually printed and published.

### *Flannelette Test.*

At an inquest held at Southport on March 22nd, on a child who died from burns through its flannelette clothing catching fire, the coroner read a letter from a Manchester manufacturer protesting against the opinions of coroners on flannelette and inclosing a sample for testing. On putting a lighted match to it the sample would have been consumed quickly if the coroner had not blown it out, and he said: "With all due respect to the manufacturer I think it would be better not to continue the test."

March 24th.

## WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

### *The Notification of Tuberculosis.*

IN some towns where phthisis is notified to the medical officers of health there appears to be a little doubt as to what subsequent action should be taken by the sanitary authority, and at a recent meeting of the South Wales branch of the Association for the Prevention of Tuberculosis the medical officer of health of Cardiff (Dr. E. Walford) suggested that female health visitors might very profitably be employed in this connexion, and it was decided to solicit the coöperation of nursing institutions and of voluntary workers.

### *A Medical Slander Action.*

At the Glamorganshire Assizes held at Cardiff on March 17th a medical man practising in Barry was the defendant in an action for slander and was ordered to pay £10 damages. The case arose out of the death of one of the defendant's patients who had been struck some time prior to his death by the plaintiff. The defendant attributed his patient's death to this blow and was said to have remarked to a friend when speaking of the affair, "It is a brutal murder." His own version of the expression used was, "It is a brutal matter." The smallness of the damages awarded makes it apparent that the jury were not very much impressed with the gravity of the slander.

### *Cardiff and County Public Health Laboratory.*

The Cardiff and County Public Health Laboratory was established about three years ago by the Glamorganshire County Council, and for the past two years has been under the joint control of the Cardiff Corporation and the county council. The second report of the bacteriologist (Dr. W. G. Savage) reveals the immense value such an institution must be to the sanitary authorities in the county. The water-supplies of Cardiff are now examined monthly and of many parts of the administrative county at fixed intervals. Altogether, 558 samples were examined during 1901. It is noticeable that there were 575 specimens for suspected diphtheria, tubercle, &c., from Cardiff examined bacteriologically and only 395 from the county, although the population of the latter is 600,000 and of Cardiff only 170,000. This disparity can hardly be due to the absence of material in the county, for diphtheria was excessively prevalent during the whole year in the large centres of population such as Merthyr and the Rhondda. In connexion with the laboratory, classes in bacteriology, chemistry, and practical outdoor sanitary work are held and were attended during 1901 by some half-dozen students.

### *Depopulation of Rural Districts.*

Most of those who have given the subject any serious consideration are agreed that the cramped and often dilapidated condition of the cottages in rural districts accounts in a great measure for the decrease in the population in those districts. The medical officer of health of the Gower peninsula in South Wales (Mr. H. E. Rawlings) in his annual report states that in his opinion if more cottages with small holdings were established it is practically certain that a large number of those who had emigrated to the towns in search of employment would return to the country to pursue a more healthy and congenial industry.

March 24th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

### *The John Usher Institute of Public Health, Edinburgh.—Arrangements for the Examination of Pathological Products for the City.*

THE John Usher Institute of Public Health, which is now almost completed, will probably be opened within the next three months. The chair of public health in Edinburgh University was founded in 1898—the necessary endowment having been provided by a legacy of £5000 from the late Mr. A. L. Bruce, supplemented by over £2000 from Mrs. A. L. Bruce and others, together with £8000 given by Sir John Usher of Norton. The Public Health Department in the new university did not, however, possess adequate laboratory accommodation for the new chair. Sir John Usher then most generously offered to build and to equip an Institute of Public Health, and it is this institute which is now nearing completion. It was at first intended that the building should occupy ground lying between the Music Class-room and the Students' Union but this site had to be abandoned as the supply of light was deficient. A site in Warrender Park-road was then adopted, where the conditions as regards light-supply are all that could be desired. The institute lies on the south side of the road and faces north. It is rectangular in form and covers an area of 133 feet by 48 feet. The exterior of the building is treated simply in classic Renaissance style. On the lintel of the main doorway three shields are to be cut, the centre one representing the Scottish Lion and the lateral shields showing the coat-of-arms of the donor, Sir John Usher, and of the Chancellor of the university, the Right Honourable A. J. Balfour. The coat-of-arms of the university will be carved on the pediment above the entrance. On the west front of the building the following inscription will be carved:—

University of Edinburgh.
The
John Usher Institute of Public Health,
Presented to the University of Edinburgh
by
Sir John Usher of Norton and Wells, Baronet.
May, MDCCCCII.

The ground floor contains entrance-hall, staircase, museum, research room, gas analysis and micro-photographic room, three laboratory workrooms designed for carrying on the bacteriological work in connexion with the public health administration of the city, two subsidiary workrooms, and caretaker's house. The first floor contains a chemical laboratory, balance room, optical room with adjoining dark room, students' reading room, water analysis room, research room, cloak room, and lecture theatre, with adjoining preparation room. Under the staging of the lecture theatre are store-rooms for apparatus, &c. On the second floor there are a bacteriological laboratory, research room, observation room, disinfection room, two incubation rooms, small lecture room for advanced class, professor's laboratory, retiring room, and library and assistant's room. In the upper storey are placed the extraction ventilation chambers and on the roof provision has been made for carrying out experiments in the open air. In the basement floor there are a refrigerating room, an incinerating room, a room containing a large centrifugal machine with electric motor, and a room for air and water pressure apparatus. Needless to say, the internal arrangements and fittings of the museum and of the various laboratories are of the most approved and up-to-date description. In giving the institute to the university Sir John Usher made the request that the University Court should provide accommodation for carrying out scientific work in connexion with the public health administration of the city. The committee of the institute accordingly set apart the three rooms above-mentioned on the ground floor of the institute for that purpose, and since 1898 has been carrying on negotiations with the town council in connexion with the matter. The Public Health Committee of the town council was not in favour of handing over the bacteriological work of the city to the Usher Institute, and a fortnight ago reported to the town council on the subject, recommending that the work should not in the meantime be taken from the laboratory of the Royal College of Physicians of Edinburgh, where it was being done in a perfectly satisfactory manner. The town council, however, refused to adopt this report and accepted the proposals of the committee of the Usher Institute. Put as briefly as possible those proposals are: 1. That the three rooms above-mentioned be entirely set apart for the city's work. 2. That a qualified assistant be appointed who shall attend exclusively to the city's work and that the services of an attendant be available. 3. That the whole work be done under the supervision of the professor of public health who shall alone be responsible to the city for the work. 4. The scope of the work to be as follows: (1) bacteriological examinations required by the medical officer of health in the daily work of dealing with infectious disease; (2) bacteriological examinations required by the sanitary inspector (these would include examinations of water, milk, food-stuffs, and flesh, and would also include examination for anthrax and glanders); and (3) bacteriological examinations of specimens in cases of diphtheria, typhoid fever, and tuberculous disease which may be sent by medical practitioners in the city for diagnostic purposes. 5. That the university agrees to perform the whole work for the outlay incurred. The committee estimates that for the investigation of 1000 specimens the cost will be about £360 per annum, this being founded on the experience of cities where a similar arrangement prevails. Of the three rooms mentioned two will be fitted with laboratories, while the third will be used for clerical work. In this third room the samples for examination will be received, the result of the examination recorded, and the reports of the results sent to the medical officer of health or to the practitioner, as the case may be. It is expected that the institute will be opened in May by the Chancellor of the university, the Right Hon A. J. Balfour, M.P.

### *Aberdeen University.*

The Aberdeen University Court met on March 11th. The secretary read a letter from the Baroness de Gurbs, intimating her desire to place a stained-glass window in King's College Chapel as a memorial of her late husband, Stephen Baron de Gurbs, a former student of Aberdeen University. It was agreed that the offer should be accepted.—It was agreed to appoint Mr. Charles Murray, M.A., M.B. Aberd., to the post of university assistant in physiology, vacant through a resignation.

March 24th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

### *Public Health of Dublin.*

THE fortnightly meeting of the Public Health Committee was held in the Municipal Buildings on March 18th, when Sir Charles Cameron reported that the death-rate from all causes in the city for the week ending March 15th was 22·2 per 10,000 persons living. This rate, he observed, was unprecedentedly low for this time of the year, the mean for the last 10 years being 34·1. The zymotic death-rate for the suburbs proved to be unusually high—namely, three per 1000, or six times that of the city.

### *Surgeon-Captain Crean, V.C.*

The Royal College of Surgeons in Ireland has decided to confer the honorary Fellowship on Surgeon-Captain T. J. Crean, V.C., in recognition of his distinguished services in South Africa. He commenced his medical studies in the College School and obtained the Licence of the College in 1895. Since the institution of the reward for "conspicuous valour in the presence of the enemy" five Irish surgeons have been awarded the Victoria Cross. Of these, one belongs to the University of Dublin, while the other four are Licentiates of the Royal College of Surgeons in Ireland.

### *An Isolation Hospital for Kingstown.*

A special meeting of the Kingstown Urban District Council was held on March 21st in the Town Hall, Kingstown, to deal with the question of a proposed isolation hospital for the township. After a lively discussion the matter was practically shelved. Mr. D. Edgar Flinn, the medical inspector of the Local Government Board, who was present, intervened, and addressing the council said that in postponing this question it had incurred a very serious responsibility by taking no steps in reference to the treatment of infectious diseases. He pointed out that the council was the custodian of the public health of the most important watering-place in Ireland, in touch with the other side of the Channel where small-pox was now epidemic. He stated that he was there at the request of the Local Government Board to convey to the council their desire that arrangements should be made for the treatment of infective diseases and to state that a temporary isolation hospital could be erected in a fortnight. Rathmines and Pembroke districts were constructing a temporary isolation hospital and such buildings were being erected all over the three kingdoms. If a case of small-pox occurred where was it to be sent? None of the Dublin institutions would admit the patient. This postponement, he said, might mean a very serious matter for the council and the responsibility was on its shoulders and not on those of the Local Government Board. At the conclusion of the meeting it was arranged that Mr. Flinn should attend the proposed meeting of the Sanitary Committee of the council.

### *The Plague.*

I HAVE on previous occasions[1] given your readers information about sundry cases of plague which occurred last year on board the *Sénégal* and about the complaints made concerning the Frioul lazaretto. The Academy of Medicine which was very anxious to find the best means of prophylaxis against the plague appointed a committee of inquiry with a view to the reform of the French sanitary service. Dr. Vallin, the secretary, made a minute investigation of the Frioul lazaretto on behalf of the committee and his report thereon was submitted to the Academy of Medicine at the meeting held on March 11th. Dr. Vallin insists on the reorganisation of the lazaretto at Frioul. There should be a medical director serving immediately under the Minister of the Interior and a sanitary station ought to be erected at the north-east point of the island of Pomègues which should be independent of the lazaretto. Quarantine for passengers should be given up but they should be compelled to be inoculated with anti-plague serum. The report suggests that the Minister of Marine should be asked to make the carriage of anti-plague serum and the instruments necessary for its administration obligatory on all merchant ships which take long voyages. The inspection of ships' medicine chests and dispensaries should be much more strict and such should be passed by the port sanitary authorities. All rats on board a ship coming from an infected port should be destroyed. Facilities should be given to medical men who may be candidates for employment in the maritime sanitary service for study at a port school of medicine so that they could acquire special professional knowledge which should be tested by examination. Finally, medical men in the service of steamship companies should be given an independent position, so that they should no longer, as is the case at present, be in the position of having to make the performance of their duty stand out in opposition to their chances of security of tenure.

---

### *The Inability of Medical Men to Inherit from Patients.*

It is well known that neither medical men nor pharmaceutical chemists in France have any legal right to receive a legacy from their patients or customers. Dr. Delarue brought before the Chamber of Deputies on Feb. 21st a proposed alteration in the law which ran as follows: "The incapacity laid down by Article 909 of the Civil Code is henceforward abrogated as far as concerns physicians, surgeons, and apothecaries." It is extremely improbable that the Chamber will pass this alteration in the law, despite the very serious reasons which exist in favour of such alteration and which were put forward by Dr. Delarue. Very often, he said, the medical man was exposed to the risk of serious illness or even of death and had to be contented with very poor pay, and, in fact, more often than not the only reward he gained by his profession was the consciousness of duty done. His devotion was always being appealed to and such appeal was never unheard. If the medical man were always to demand remuneration for his work it would be impossible to make certain that the hospital service should be carried on or that the regulations of the Assistance Publique should be duly complied with. Official salaries were increasing and also retiring pensions but there was nothing to help an old physician who had devoted perhaps 40 years of his life in the service of his equals. Moreover, the law as it existed at present did the medical men the injustice of apparently suspecting every medical man to be capable of abusing the power which he possessed over his patients for the purpose of getting hold of their money and of making them carry out their last wills and testaments in opposition to their own wishes. Why did not the law inflict the same disabilities on other professional men, such as barristers or solicitors who had just as much influence over their clients as medical men had over their patients. There was no good explanation why medical men should be thus treated. As for apothecaries, they had nothing to do with the treatment of patients, for their only duty was to send in medicine prescribed by the medical man.

### *Photo-therapy and the Iron Electric Arc.*

On March 3rd M. A. Broca and M. Chatin laid before the Academy of Sciences the results of their attempt to utilise an iron electric arc in photo-therapy. They have managed to obtain a perfectly steady arc which takes a current of from 10 to 30 ampères. This arc is very rich in actinic rays which are alone of use. Exposure to it for five seconds reduces ordinary silver photographic paper to a deep red-violet colour. Moreover, it gives hardly any heat rays and so the patient can be placed within 10 centimetres of the apparatus, while the need for a cooling jacket is done away with. The simplification of the apparatus allows of much more exact compression of the affected region being employed than has hitherto been the case with other apparatus, and M. Broca and M. Chatin have used the process at the St. Louis Hospital in nine cases of lupus with excellent results. The arc is covered by a metallic sleeve with a hole of three centimetres in diameter opposite the patient, so that the assistants are completely protected. With an iron arc taking from 15 to 18 ampères and an exposure of from 19 to 25 minutes very remarkable cutaneous reactions were produced in all the patients. They appeared from some 24 to 48 hours after the exposure. Phlyctenulæ comparable to those seen after the use of the Finsen and similar apparatus were noticed, but the light rays appeared to exercise a selective influence on the lupus nodules which were profoundly affected, although the periphery of the ulcer and the healthy skin only showed a slight raising of the epidermis. These results would seem to foreshadow a great future for this method which in addition to giving rays of increased actinic power enables photo-therapy to be carried out without the use of the cooling apparatus which, besides being very complicated, absorbs a certain amount of light rays.

### *Action against the Director of a Lazaretto.*

A curious case is now before the courts. Last year a ship arrived from Brazil at Bordeaux on board of which was a young woman far advanced in pregnancy whom the medical officer of the lazaretto compelled to disembark as he suspected that she was suffering from yellow fever. Within a few hours she died and was hurriedly buried. The husband hastened to the spot and, having obtained an exhumation order, found not only the body of his wife but also that of an infant lying between her legs. Now he has haled the medical officer before the courts, declaring that his wife was not suffering from yellow fever but only from troubles incidental to pregnancy. He further declares that she was buried alive and that the birth of the child followed spontaneously on the burial. So, then, this case raises a curious point in obstetrics as well as the question of the responsibility of medical officers of lazarettos.

March 24th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *Bacilli in the Seminal Fluid in Syphilis.*

AT the last meeting of the Berlin Medical Society Dr. Joseph and Dr. Piorkowsky showed specimens of bacilli discovered by them in cases of syphilis. They examined the semen of syphilitic persons, because in many instances a man without manifest symptoms of syphilis has been known to communicate the virus to a healthy woman by way of the placenta, the effect being that she does not exhibit evidence of the disease until she becomes pregnant. They described their procedure as follows. Semen was obtained from 22 men who had contracted syphilis at different periods varying from five weeks to two years previously and was placed in contact with sterilised pieces of placenta, on which as a nutrient medium there was an abundant bacterial growth, containing after 12 hours long bacilli with clubbed ends resembling those of diphtheria. Cultures transferred from the pieces of placenta could be grown upon agar and blood serum, but direct inoculation of the semen upon agar without previous use of placenta gave no result. The colonies growing on agar developed very quickly but soon showed signs of degeneration which could be made to disappear by reinoculation of the cultures on placenta. The bacilli were stained by Gram's method and could be agglutinated by serum. In five cases of syphilis which had lasted for periods varying from three to 10 years the results were negative. The bacilli were not present either in normal semen or in cases of azoöspermia occurring in syphilitic men. Inoculation into animals gave no decided result. A pig after inoculation developed a peculiar exanthem on the genital organs together with a swelling of the lymphatic glands, but as it died six days later from an epizoic malady these symptoms might perhaps have been due to the latter cause. Dr. Joseph was of opinion that the bacilli discovered by him were specific for syphilis but further investigation on a larger scale was necessary. In the ensuing discussion Professor Jürgens of the Pathological Institute said that similar bacilli had already been described by Dr. Von Nissen. He pointed out that in one of the specimens there were no bacilli but there were spores, so that a mixed infection had perhaps occurred. He recommended that cases of congenital syphilis should be included in the observations, because in them it was possible to avoid mixed infections. Dr. Aronson said that chronic diseases were usually of slow development and considering the rapid growth of Dr. Joseph's bacilli it was unlikely that they were the cause of so chronic a disease as syphilis. Dr. Joseph, in his reply, said that as regards the bacterial origin of syphilis he had been careful to speak with all reserve but he thought it right to mention that the bacilli in question had never been found in normal semen.

### *Medical Experts in the Law Courts.*

The trial of Professor Dührssen, of which an account appeared in THE LANCET of March 15th, 1902, p. 779, has directed attention to the state of the law relative to medical evidence given before courts of justice. As a general rule the medical officer of health of the district is *ex officio* medical expert in the courts but in some of the larger towns special medical officers have been appointed for this duty. In cases of considerable importance and in appeal cases recourse is had to the provincial board which exists in each province (Provincial Medicinal-Collegium) composed of professors of the university of the province together with Government medical officers and others, and to a central board in Berlin (Wissenschaftliche Deputation für das nalwesen) composed of professors of Berlin University only. The professional opinions given by the authority last named have a great influence on the decisions of the courts, for the judges believe that no expert is more competent in medical questions than this board and its opinion is very seldom disregarded. Since the Dührssen trial, however, some medical journals have pointed out that although the board is composed of the leading medical men of Berlin its formally expressed opinions nevertheless do not possess the weight and importance with which they are usually credited. When in a given case the opinion of the board is asked by a public prosecutor or by a court of justice the president of the board, as a rule, entrusts the matter to a member who is a specialist in that department. If, for instance, a surgical case is under consideration it is one of the surgeons or if it is a gynæcological case it is the gynæcologist who draws up the report. There is no discussion of the matter by the whole board; when the report is prepared it is signed by the other members but in reality the opinion of the board is only the opinion of one member whose views may sometimes be out of date and who is by no means superior to other specialists who may be called by the other side. Moreover, the opinion of the board or of the member who acts in its name has to be based on written statements, for the patient is very seldom examined with a view to the preparation of the report. It is also quite unusual for members of the boards to attend a court as witnesses or to undergo cross-examination; a member of the provincial board was present at the trial of Professor Dührssen but the central board was not represented at all. Some medical journals now propose that this system should be altered by abolishing the boards and that in cases of considerable importance the opinions of the most competent men in the respective branches of medicine should be asked, as they would be required to appear in court and after being sworn as experts might be cross-examined like other witnesses.

### *The Congress of Naturalists and Medical Men.*

The seventy-fourth congress of the German Association of Naturalists and Medical Men will this year be held beyond the borders of the German Empire—namely, in Carlsbad, the famous mineral water resort in the Austrian province of Bohemia. The congress will meet in two principal sections—a medical one with 17 subdivisions and a scientific one with 11 subdivisions. The medical subdivisions are as follows: (1) anatomy, histology, and physiology; (2) general pathology and pathological anatomy; (3) clinical medicine, pharmacology, balneology, and hydrotherapeutics; (4) history of medicine; (5) surgery; (6) obstetrics and diseases of women; (7) diseases of children; (8) nervous and mental diseases; (9) ophthalmology; (10) diseases of the larynx, nose, and ear; (11) dermatology and syphilis; (12) odontology; (13) military medicine; (14) forensic medicine; (15) hygiene; (16) veterinary medicine; and (17) pharmacy. In the medical section the official subject of discussion will be physiological albuminuria and in the scientific section it will be the circulation of nitrogen.

### *"Christian Science."*

The fantastic doctrines known by the name of "Christian science," with which the name of Mrs. Eddy is associated, continue to occupy the attention of the public, and it is said that they have made more progress, especially among females, than is generally supposed. Believers abound in Potsdam, where the Emperor's summer residence is situated, and many of the nobility and court officials engage in the exercises prescribed by Mrs. Eddy. The Emperor has expressed strong disapproval of these proceedings, and has caused it to be announced that persons who attend the meetings or in any other way encourage the new system will not be admitted to Court.

March 24th.

---

**THE EXAMINER IN PHYSICS AT EDINBURGH UNIVERSITY.**—The Edinburgh University Court, which met on March 17th, appointed Mr. Dawson F. D. Turner, M.D., F.R C.P. Edin., examiner in Experimental Physics to the University. We believe that this university is the first to have recognised the importance of having an examiner who has received a medical training to examine medical students in physics.

## Obituary.

### WILLIAM TOWLSON KAY, M.R.C.S. ENG., L.R.C.P. EDIN.

THE death is announced of Mr. W. Towlson Kay, late of Gateshead, which occurred at Eastbourne on March 9th. Mr. Kay was born in 1849 and was a student at the Newcastle-on-Tyne College of Medicine, where he had a distinguished career. After securing his diplomas he was appointed medical tutor to his college for a time when he joined the late Dr. Dixon of Gateshead in partnership. Later he practised on his own account and soon secured a large and good practice. He was appointed surgeon to the Gateshead police, a post which he held for 25 years. Three or four years ago his health began to fail and in October, 1900, he retired from practice and went to live at Eastbourne. For a time his health improved but in the autumn of last year he had a relapse which ended fatally on March 9th. Mr. Kay was a great favourite with his patients owing to his genial manner and assiduous attention to them. He took no part in public life but was a member of the local medical societies. He leaves a widow but no children.

### JOHN BARCLAY, M.D., C.M. ABERD.

DR. BARCLAY of Banff died at his residence there on March 11th, after a lingering illness. He received his medical education at the University of Aberdeen, where he graduated in 1862, and was then appointed assistant professor of materia medica and medical jurisprudence. 30 years ago he commenced practice in Banff and built up one of the largest medical practices in the county of that name. He held many public and official appointments in Banff. Dr. Barclay acted as an examiner at Aberdeen University from 1880 to 1883. His wife, who was a daughter of the late Provost Coutts of Banff, predeceased him several years ago. He leaves two sons and two daughters.

### HUGH FRASER, M.B., C.M. ABERD.

A CABLEGRAM was received in Aberdeen on March 11th stating that Dr. Hugh Fraser had died from enteric fever at Bethulie, South Africa, on March 4th. After graduating at Aberdeen University Dr. Fraser came to England, and some four years ago he proceeded to King Williamstown, Cape Colony, where he was stationed until a few months ago, when he accepted the position of medical officer in the camp at Bethulie. Dr. Fraser was the youngest son of the late Dr. George Innes Fraser of Aberdeen. The deepest sympathy is felt for Dr. Fraser's mother in her sudden and unexpected bereavement.

## Medical News.

**SOCIETY OF APOTHECARIES OF LONDON.**—In March the following candidates passed in the subjects indicated:—

*Surgery.*—C. R. Bradley (Section I.), St. George's Hospital; S. J. H. M. Eastwick Field, Royal Free Hospital; J. W. Elliott (Section I.), St. Mary's Hospital; H. S. French (Sections I. and II.), Oxford and Guy's Hospital; K. Heanley (Section I.), Royal Free Hospital; E. O. Libbey, Leeds; and S. C. Wilkinson (Sections I. and II.), Leeds.

*Medicine.*—F. G. Bennett (Section II.), University College Hospital; W. T. Colyer, Cambridge; H. S. French (Sections I. and II.), Oxford and Guy's Hospital; R. Gauld (Sections I. and II.), London Hospital; K. Heanley (Section I.), Royal Free Hospital; W. St. A. F Hubbard (Sections I. and II.), Charing Cross Hospital; O. Millauro (Section I.), Westminster Hospital; H. H. Sloane (Section II.), St. Bartholomew's Hospital; W. P. Taylor, Sheffield and Bristol; J. E. Turle (Section I.), University College Hospital; and A. F. Van Dijk (Sections I. and II.), St. Bartholomew's Hospital.

*Forensic Medicine.*—H. S. French, Oxford and Guy's Hospital; W. St. A. F. Hubbard, Charing Cross Hospital; W. P. Taylor, Sheffield and Bristol; J. E. Turle, University College Hospital; A. F. Van Dijk, St. Bartholomew's Hospital; and J. H. Williams, London Hospital.

*Midwifery.*—D. Cotes-Preedy, Cambridge and St. George's Hospital; G. M. Crockett, Royal Free Hospital; E. F. Forjett, Edinburgh; H. S. French, Oxford and Guy's Hospital; H. M. Jones, Royal Free Hospital; J. A. Kilpatrick, King's College Hospital; M. E. Martin, Royal Free Hospital; H. H. Sloane, St. Bartholomew's Hospital; G. B. S. Soper, Guy's Hospital; and S. Zweiback, Königsberg.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: W. T. Colver, S. J. H. M. Eastwick Field, H. S. French, E. O. Libbey, S. C. Wilkinson, and J. H. Williams.

THE Dawlish and Teignmouth District Councils have decided to erect a joint isolation hospital.

LARYNGOLOGICAL SOCIETY OF LONDON.—The ordinary meeting of this society has been postponed to Friday, April 11th, at 5 P.M.

VACCINATION GRANT.—Mr. David T. Key, M.R.C.S. Eng., L.S.A., public vaccinator for Wyke Regis, has received for the first time the Government grant for successful vaccination.

AT a public meeting at Peterborough last week it was decided to commemorate the Coronation of King Edward VII. by raising by voluntary subscription a sufficient sum to add a new wing to the hospital presented to the city by the late Earl Fitzwilliam.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—The Organising Committee of King Edward's Hospital Fund for London, 81, Cheapside, E.C., has signified that it has much pleasure in accepting an offer which has been made to it with regard to Mr. Percy Godfrey's "Coronation March." This proposal is to the effect that *6d.* derived from the sale of each copy of the march shall be devoted to the "coronation gift" and that all sums derived from licences to perform the march and collections made at concerts shall be given to the same object. Mr. Godfrey's composition gained the prize recently offered by the Worshipful Company of Musicians for the best coronation march, the adjudicators being Sir Frederick Bridge, Sir Walter Parratt, and Sir Hubert Parry.

THE ROYAL INSTITUTION.—In a lecture on Some Electrical Developments delivered at the Royal Institution on March 22nd Lord Rayleigh said that although the Roentgen rays were so easily produced and were capable of giving such remarkable effects, their essential nature was in several respects unknown. They travelled in straight lines and could neither be refracted nor reflected, from which it necessarily followed that they could not be polarised. Diffraction experiments made with great care by Dutch investigators had led to no result beyond proving that if the rays had an undulatory character their wave length could not exceed the one-hundredth of that of light. As was well known, they produced photographic effects by the decomposition of silver salts and rendered certain fluorescent substances luminous; the only other respect in which they were found to resemble ordinary light was that both the Roentgen rays and the ultra-violet rays of the luminous spectrum caused electric leakage of gases. At one time it was supposed that the Roentgen rays admitted of partial reflection but it was now considered that the apparent effect was probably due to some secondary emission. There were many points of resemblance between Becquerel rays and Roentgen rays. Becquerel formerly believed that the rays discovered by him could be polarised but this view was now abandoned. Roentgen rays could be deflected by magnets and experiments were shown in which the rays passing through a hole in an aluminium plate and falling on a fluorescent screen were by means of magnets displaced both in straight lines and in curved lines. Changes produced in jets of steam and water by electrification were also shown. In another experiment common air was blown through a Woulfe's bottle containing sulphuric acid which did not cover the end of the inlet tube, so that the air did not bubble through the acid but merely passed over its surface. A jet of steam cast only a faint shadow on a screen when a beam of electric light was turned on it, but when the air from the Woulfe's bottle was directed against the jet of steam the shadow became much darker. When nitric acid was substituted for the sulphuric acid the effect did not take place. Lord Rayleigh said that the cause of this phenomenon was quite unknown and he recommended it to the notice of young experimenters because of the simplicity of the apparatus required.

NOTIFICATION OF CHICKEN-POX.—The Bath Rural District Council on March 12th decided to include chicken-pox in the list of notifiable diseases.

BRIDGWATER INFIRMARY.—On March 20th Colonel W. Barratt, the president of the Bridgwater Infirmary, formally opened the new operation room which has been provided by means of a bequest of £300 left for that purpose by the late Mr. George England.

ROYAL HOSPITAL FOR INCURABLES, DUBLIN.—A meeting of the board of governors of this hospital was held on March 18th, when six new patients were elected. The hospital is entirely unsectarian and provides accommodation for 212 patients, including separate wards for the treatment of 72 patients suffering from cancer and consumption, in addition to 140 inmates afflicted with various other incurable maladies, all of whom are disqualified for admission into the general hospitals. The average daily number of beds occupied throughout last year was 203 and further financial assistance is urgently needed to reduce a debt of £974.

BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—During the past year 3285 new out-patients have attended at this hospital, showing a decrease of 38 as compared with last year's figures. The total number of new and old cases treated during the year was 17,174, being 570 less than last year. 440 patients were admitted to the in-patient department, an increase of 13 on last year and the total number of operations was 422, an increase of 12. The number of operations involving abdominal section was 213—that is, nine more than last year; of these nine patients have died, giving a death-rate of 4·2 per cent. This compares with 2·94 per cent. on 204 operations in 1900.

DOWN DISTRICT LUNATIC ASYLUM.—On March 15th at a meeting of the committee of management of the Down District Lunatic Asylum the following motion with reference to the necessity for the establishment of a central laboratory in Ireland for the investigation of the pathology of insanity was unanimously carried: "That we, the committee of management of Down District Asylum, desire to express our warm approval of the proposed central laboratory for research in the pathology of insanity; we hereby state our readiness to affiliate this institution with such an undertaking when it assumes a practical shape and to contribute towards its maintenance a sum of £25 per annum. We are of opinion that the project is deserving of general support, believing, as we do, that the prevention and the most effective treatment of mental disease must be largely aided by an accurate knowledge of the morbid physical conditions associated with it, and feeling that any step that tends to promote such knowledge must ultimately prove an important factor in the reduction of the burden of the lunacy charges of the country."

DONATIONS AND BEQUESTS TO HOSPITALS.—The Lord Mayor and Lady Mayoress of London have contributed 20 guineas to the Royal Hospital for Diseases of the Chest, City-road, London, towards the fund now being raised to build and to furnish a home for the nursing staff.—The committee of the Hospital for Consumption, Brompton, has received £1000 from the Goldsmiths' Company and £105 from the Mercers' Company for the country branch of the hospital at Bagshot where the open-air treatment of phthisis is to be carried out.—By the will of Miss Frances Hester Robinson of Richmond £2000 are bequeathed to the British Home for Incurables at Streatham, £2000 to the Deaf and Dumb Asylum in the Old Kent-road, £2000 to the School for the Indigent Blind (for the Junior Branch at Wandsworth), £2000 to the Society for Granting Annuities to the Poor Adult Blind, £1000 to the Charing-cross Hospital, and £1000 to the Hospital for Consumption and Diseases of the Chest, Fulham-road.—Under the will of the late Miss Olivia Atherton of Everton the Royal Infirmary (Liverpool), Northern Hospital (Liverpool), Southern Hospital (Liverpool), and Liverpool Country Hospital for Chronic Diseases receive £1000 each; the Hospital for Women (Liverpool), the Eye and Ear Infirmary (Liverpool), the Liverpool Dispensaries, Liverpool Children's Infirmary, Bootle Hospital, and Stanley Hospital receive £500 each; the Children's Convalescent Home at West Kirby, Wirral Children's Hospital, Home for Incurables, Cancer Hospital (Liverpool), and Liverpool Hospital for Consumption receive £250 each; and the Wallasey Cottage Hospital (Liverpool) receives £200.

**Health of Tiverton Rural Distict.**—Mr. J. R. R. Pollock, the medical officer of health, reports that during 1901 the birth-rate in this Devonshire rural district was 25·51 per 1000, and the death-rate was 14·81 per 1000.

**Defective Drains.**—At the Bristol County Court on March 18th a tenant claimed from the owner of a house £50 damages for alleged breach of warranty respecting the drains. The plaintiff stated that when he took the house from the defendant he was assured that the drains were in perfect condition. After a few months members of the family were constantly ill and one child died from diphtheria. Eventually the plaintiff communicated with the sanitary authority and the drains were found to be defective. The defendant stated that he gave no warranty; all he said was that to the best of his belief the drains were all right. Judgment was given for the plaintiff for £25, with costs.

**Cheltenham General Hospital.**—The annual meeting of the subscribers to this institution was held on March 18th under the presidency of Colonel Croker-King. The medical report stated that 896 in-patients had been admitted during 1901, against 871 in 1900, and there had been 8867 out-patients treated compared with 7936 in the preceding year. The financial statement showed that there was a small increase in church collections and Hospital Saturday collections and the legacies received amounted to £2250, but the excess of expenditure over income nevertheless amounted to £2419. Colonel Croker-King was re-elected president.

**Torbay Hospital, Torquay.**—There is some difficulty at Torbay Hospital with respect to a rule which was adopted by the committee last year providing for the annual election of the honorary medical staff. At the recent election two of the physicians, who were originally appointed for life, were not re-elected although they were thanked for their past services. The board of management then advertised for two gentlemen to fill the vacancies. The members of the profession in Torquay at a meeting agreed that none of their number should apply for the appointments and consequently no applications were received. The honorary medical staff of the hospital feel strongly on the subject of the rule alluded to and six influential governors have requisitioned a special meeting with the object of getting the rule altered.

**Winsley Sanatorium.**—A public meeting in aid of the proposed sanatorium for consumptives for Somerset, Wilts, Gloucestershire, and Bristol was held at Bath on March 13th under the presidency of the Mayor (Mr. E. E. Phillips, L.R.C.P. Edin., M.R.C.S. Eng.). Dr. L. Weatherly mentioned that the members of His Majesty's Advisory Board who recently visited the Winsley Sanatorium, although they regarded it as an admirable spot for such an institution, found that the space would be too small for the erection of the King's Sanatorium for which Sir E. Cassell had given £200,000. It was stated that £20,000 would be needed for the erection of the proposed sanatorium; £5000 had only been received at present, and it has been resolved that the foundation-stone shall not be laid until one half of the required sum has been raised.

**Birmingham General Hospital.**—The report of this institution for 1901 states that the old hospital which was sold to the corporation has now been pulled down and a building which for 130 years did so much for the relief of the sick and suffering passes away in all but memory. The demand on the beds, though great in previous years, has been even greater during the past year, the list of cases awaiting admission often exceeding 200 and it has rarely dropped to 100. The number of in-patients was 5170, a decrease of 41 as compared with the previous year. The daily average of patients in the hospital was 278, against 281½ in 1900. Of the in-patients admitted 902 were children under 12 years of age, of whom 138 were under the age of two years. The out-patients numbered 62,643, or 1778 more than in the previous year. The amount accruing from subscriptions, &c., was £7747 17*s.* 8*d.*, or £469 3*s.* 8*d.* more than in the previous year. Donations amounted to £582 0*s.* 5*d.* and special congregational collections to £52 0*s.* 5*d.* £2973 6*s.* 8*d.* were placed to the credit of the current account as the moiety of legacies received during the year. The ordinary expenditure was £24,411 9*s.* 11*d.* and the extraordinary expenses amounted to £812 17*s.* 2*d.*, while the sum of £276 8*s.* 5*d.* was transferred to the Jaffray branch account to meet the deficit at that institution. An adverse balance of £5110 19*s.* 1*d.* remained at the end of the year, the surplus of £1180 5*s.* 10*d.* shown on the year's working being applied to the reduction of the deficit of £6291 4*s.* 11*d.* brought over from last year.

**Health of Launceston.**—Dr. C. G. Gibson, the medical officer of health of Launceston (Cornwall), in his annual report for 1901 states that during the year the births numbered 59 and the deaths 48. The birth-rate was 14·5 per 1000 and the death-rate was 11·84 per 1000. Dr. Gibson urged the town council to provide an isolation hospital for small-pox cases.

**Dorset County Hospital, Dorchester.**—The sixty-first annual report of this institution which has just been issued states that 299 in-patients were admitted during 1901, against 311 in 1900. The out-patients numbered 961 compared with 996 in the previous year. The average daily number of in-patients was 33; the average cost per patient weekly amounted to £1 0*s.* 2*d.* The financial statement shows that the receipts for the year amounted to £2165 and the expenditure to £2284. The deficit balance at the end of 1900 amounted to £18 and this has now been increased to £137. During the present year it is hoped to provide the hospital with a new operation room, and owing to munificent donations from the Earl of Eldon and the Earl of Ilchester the committee hope that the work will be completed without any call being made on the general funds of the institution.

## NOTES ON CURRENT TOPICS.

### *Midwives Bill.*

In anticipation of the report stage of the Midwives Bill several amendments have been prepared and put down on the notice paper of the House of Commons. Mr. Griffith-Boscawen and Mr. Robert Ambrose propose to raise once more the question of the scope of the legislation by moving amendments to make it apply to all women who habitually and for gain attend midwifery cases, while Mr. George Harwood has put down a notice to strike out the subsection inserted at the instance of Sir John Batty Tuke in the Grand Committee which proposes that no woman shall be entitled to recover fees in the courts unless she is certified under the Act. In Clause 2 Mr. T. P. O'Connor will move to strike out the words which give special recognition to the certificates in midwifery of the Royal College of Physicians of Ireland and the Obstetrical Society of London. Several amendments appear in the notice paper with reference to Clause 3, the clause dealing with the constitution and duties of the Central Midwives Board. Mr. Patrick White proposes that the General Medical Council and not the Lord President of the Privy Council shall take the steps for the formation of the Board; Mr. McGovern that the four registered medical practitioners shall be appointed by the General Medical Council instead of by the Royal College of Physicians of London, the Royal College of Surgeons of England, the Society of Apothecaries, and the Incorporated Midwives Institute; and Mr. Griffith-Boscawen that the Royal British Nurses Association shall have a nominee on the Board. With this substantial body of amendments on the notice paper the Bill cannot be taken as unopposed business after midnight. In all probability, therefore, it will have to wait its turn with other private Members' Bills for consideration on a Wednesday after Whitsuntide, unless, of course, the Government arranges to give special facilities.

## HOUSE OF COMMONS.

### Tuesday, March 18th.

### *Vaccination in Government Departments.*

Mr. Channing asked the Vice-President of the Committee of Council on Education whether he was aware that on Feb. 19th a general order was issued on behalf of the Board of Education and signed by Sir William Abney inviting the officers of the department at South Kensington to submit themselves for vaccination and revaccination by the public vaccinator on Feb. 25th and 26th, and desiring those who did not wish to do so to send in their names to the heads of their sections; whether there had been issued since then a further minute, signed by Sir William Abney, inviting officers who still remained unwilling to reconsider the matter before the Board proceeded to decide what further steps should be taken; whether any similar action had been taken on the elementary side at Whitehall and in other Government departments; whether the order and minute were issued by Sir William Abney with the sanction of the Lord President and Sir George Kekewich; and, if so, under what powers, statutory or by regulation, any further steps to compel the officers to be vaccinated or revaccinated could be taken.—Mr. Grant Lawson, replying for Sir John Gorst, said: Notices relating to the vaccination of persons in the employ of the Board of Education have by the authority of the Board been issued both at Whitehall and South Kensington. Similar notices have, I am informed, been issued by other Government departments. No person can be compelled by the Board of Education to be vaccinated or revaccinated.

#### *The Water-supply at Darenth.*

Dr. FARQUHARSON asked the President of the Local Government Board (1) whether he was aware that the Kent Waterworks Company had nearly completed a large pumping station in the parish of Darenth in the Darenth valley, within 1100 yards of the inclosure at Gore Farm in which the Metropolitan Asylums Board had also nearly completed small-pox hospitals to hold a total of 2500 cases; and that the pumping station was at a lower level than any part of this inclosure; and (2) seeing that these small-pox hospitals and the other establishments belonging to the Metropolitan Asylums Board at Gore Farm had no means of drainage for liquids other than soakage into the porous gravels and sands overlying the chalk strata from which the Kent Waterworks derive their supply, whether he would institute an inquiry into the effect on the quality of the water-supply from this drainage, including that from the burial-ground belonging to the Metropolitan Asylums Board at Gore Farm, in which between 1500 and 1600 interments of small-pox and scarlet fever patients had been made, this burial-ground being situated 160 feet higher than, and 1700 yards distant from, the Kent Waterworks Company's pumping station.—Mr. GRANT LAWSON replied for Mr. LONG, saying: I am aware of the facts mentioned in the first paragraph of the question. The well was approved by me in December last as a source of supply after an investigation by an inspector and after samples of the water had been examined by experts and found to be of great organic purity. I am informed that there is no danger of the well being polluted by surface drainage as it is lined with closely fitting iron cylinders to a depth of 92 feet from the surface, the lower 60 feet being in the solid chalk. Moreover, I understand that Gore Farm drains into a subsidiary valley of the Darenth, which enters the main valley fully half a mile below the site of the well, and it is therefore impossible for surface drainage from the hospital lands to reach the vicinity of the well.—Dr. FARQUHARSON asked whether the Local Government Board would send down an inspector in order to relieve the local anxiety on this subject.—Mr. GRANT LAWSON: An inspector was there as recently as last November. He made a close inspection and, as I have said, the water was then submitted to analysis, I do not think it is necessary to do it again.

### THURSDAY, MARCH 20TH.

#### *Vaccination Questions.*

Mr. ROUND asked the President of the Local Government Board if his attention had been called to the danger of infection in schools from children who had not been vaccinated; and if he would take steps, if necessary by legislation, to empower school authorities to exclude such children from attendance at school.—Mr. LONG replied: I am aware of the danger referred to where small-pox is prevalent but it mainly affects children who are not protected by vaccination. I may, however, point out that under Article 88 of the Code of Regulations made by the Board of Education, the managers of any public elementary school must comply with a notice of the sanitary authority of the district or of two members acting on the advice of the medical officer of health, requiring them for a specified time with a view to preventing the spread of disease to exclude any scholars from attendance. There is a right of appeal to the Board of Education if the notice is considered unreasonable. I understand that in one case unvaccinated children have been excluded under the article.

Mr. CORRIE GRANT asked the President of the Local Government Board whether he was aware that Dr. S. M. Copeman inoculated monkeys with small-pox material obtained from cases under observation during outbreaks of the disease, that he inoculated calves from the vesicles so produced on the monkeys, and inoculated a considerable number of children from the vesicles so produced on the calves, as described by himself in a paper read before the Royal Medical and Chirurgical Society on Dec. 10th, 1901; whether these experiments were conducted with the knowledge of the parents or with the knowledge or sanction or at the expense of his department; and whether Dr. Copeman was now or had been in the employment of the Government.—Mr. LONG, in reply, said: The answer to the first two points is in the affirmative. I am informed that a considerable number of children were vaccinated with the lymph obtained from the calves referred to but none of the vaccinations were performed by Dr. Copeman. I have no information as to whether the experiments were conducted with the knowledge of the parents of the children vaccinated but they were not performed with the knowledge or sanction or at the expense of the Local Government Board. Dr. Copeman is one of the medical inspectors of the department.

### FRIDAY, MARCH 21ST.

#### *Enteric Fever among the Troops in South Africa.*

Sir WALTER FOSTER asked the Secretary of State for War if he could state the names of the special sanitary officers who had been sent to South Africa to inquire into the origin and spread of enteric fever and other preventable diseases among the troops, with the dates of their appointments, the length of time spent in South Africa on these duties, and the duties on which they were now engaged.—Mr. BRODRICK replied: Three gentlemen were specially employed in August, 1900, to inquire into the subjects mentioned—Dr. Simpson, Colonel J. L. Notter, R.A.M.C., and Major Bruce. Dr. Simpson served until November, 1901, with an interval of five months, when he was employed on plague duties. He has now gone to Hong-Kong to investigate the recurrence of plague there. Colonel Notter served till October, 1901, when he returned to England. He is now acting as principal medical officer at Aldershot. Major Bruce served till October, 1901. He is now serving on the Advisory Board for Medical Services. Captain Beveridge and Colonel Cooper, R.A.M.C., who were already in South Africa, were also employed in the same work. The recommendations of these gentlemen are being carefully carried out by the responsible medical officers on the spot.

While the House was in Committee of Supply discussing the vote for the salaries and expenses of the War Office Sir WALTER FOSTER made a speech on this subject. He argued that the wastage among the troops from enteric fever was not taken sufficiently seriously. During the months of January and February of the present year there had been 800 deaths among the soldiers—a mortality heavy in itself and representing a large amount of disability through sickness. This drain on the forces, he submitted, was not creditable to the administration. He had been told by the Secretary of State that he was advised by civilian medical men in the best practice in London, but what he stood in need of were the guidance and advice of special experts in sanitary matters—leading medical officers of health or experienced inspectors under the Local Government Board. There were no fewer than 60 places where the mortality from enteric fever was excessive. The disease was preventable and he thought special pains should be taken to protect the soldiers from it. He would like to know whether anything was being done in the way of providing the columns with the means of boiling water.—Mr. BRODRICK said that he agreed with the hon. Member as to the seriousness of the wastage from this disease, but he would remind him of the difficulty there was in enforcing any regulations or precautions that might be prescribed. Regulations might be enforced in a civil community, but the case was entirely different with a moving army scattered over so wide a region as South Africa. Soldiers tired and thirsty would drink water whenever they came across it. A column arrived at a place and while food was being prepared the men in defiance of regulations made off to the river and drank the water. In this way the very best precautions were rendered of no avail. At the same time he fully appreciated the force of the hon. Member's speech and he assured him that the matter would have his best efforts and attention.

#### *Medical Staff of the Refugee Camps.*

Mr. LAMBERT asked the Secretary of State for the Colonies whether any of the medical staff of the refugee camps had complained of their treatment by the chief superintendent, and whether the same had been dismissed by him without notice or reason assigned.—Mr. CHAMBERLAIN said: No, sir; I have not received any complaints, but I think that I ought to add that I have absolute confidence in Sir William Maxwell, the superintendent of the concentration camps and the military governor of the district, and that I should not think of interfering with his discretion in dealing with his subordinates.

### TUESDAY, MARCH 25TH.

#### *Colonel's Pay in the Royal Army Medical Corps.*

Captain NORTON asked the Secretary of State for War if he could state the total pay and allowances of a colonel on the general staff, a colonel on the staff of the Royal Engineers, and a colonel of the Royal Army Medical Corps respectively, and whether any increase of total emoluments for the last-mentioned officer had been arranged for in the forthcoming warrant for the Royal Army Medical Corps.—Lord STANLEY replied for Mr. BRODRICK: The pay and allowances are as follows: Colonel on the staff, £880 and forage; Colonel on the staff (R.E.), £1063 and forage; Colonel of the R.A.M.C., £880 and forage. The recent Committee on the Reorganisation of the Army Medical Service did not recommend any increase to the emoluments of colonels of the Royal Army Medical Corps and no increase is therefore provided for officers of this rank in the forthcoming warrant.

#### *Small-pox Statistics.*

Mr. CORRIE GRANT asked the President of the Local Government Board, having regard to the fact that the system of classification of small-pox deaths, according to a footnote in the weekly return of the Registrar-General, excluded from the classes of vaccinated and not vaccinated all cases not so certified by registered medical men and that cases were put under the heading "no statement" not only when the medical practitioner was unable to certify whether there had been vaccination or not but when the practitioner had failed to make any mention of vaccination, whether he would direct the Registrar-General to secure a stricter classification of the small-pox deaths.—Mr. GRANT LAWSON, for Mr. LONG, replied: I have communicated with the Registrar-General who states that he does at present secure a classification of small-pox deaths which is sufficiently accurate for statistical purposes. Frequently it is not practicable to obtain full information concerning particular cases in time for publication in the current weekly returns but from time to time the information is supplemented with the help of facts subsequently obtained. The Registrar-General will, however, consider whether any alteration shall be made as regards the publication of vaccination statistics in connexion with deaths from small-pox.

#### *Bubonic Plague in Hong-Kong.*

Mr. WEIR asked the Secretary of State for the Colonies if he would state the percentage of the bubonic plague cases in Hong-Kong for each month since August last inclusive; and, in view of the fact that the plague was largely attributed by the Legislative Council of Hong-Kong to the prevalence of rats, would he say whether effect had been given to the council's proposals to employ an English rat-catcher; and, if so, with what result.—Mr. CHAMBERLAIN replied: The number of plague cases in Hong-Kong was—for August, 20; for September, 22; for October 3; and one case occurred in each of the three months, December, January, and February. I have urged upon the Colonial Government the necessity of destroying rats and very large numbers have been killed, but no such proposal as that referred to by the hon. Member has been brought to my notice.

#### *Typhoid Fever Epidemic in Ireland.*

Mr. TULLY asked the Chief Secretary to the Lord Lieutenant of Ireland if he could say what was the nature of the report of Dr. McWeeney as to the outbreak of typhoid fever in Boyle Union in connexion with a local creamery; and could he state why no steps were taken to act on this report and to close the creamery during the epidemic.—Mr. WYNDHAM said in reply: The report was unfavourable. The creamery was closed for some days, during which the structural defects were remedied. The Local Government Board inspector considers the creamery may now be worked without danger to the public health.

## BOOKS, ETC., RECEIVED.

BAILLIÈRE, J. B., ET FILS, 19, Rue Hautefeuille, Paris.

Les Oxydations de l'Organisme (Oxydases). Par E. Enriques, Médecin des Hôpitaux de Paris, et J. A. Sicard, Chef de Clinique à la Faculté de Médecine de Paris. ("Actualités Médicales" Series.) Price 1 fr. 50c.

Essex and Colchester General Hospital.—House Surgeon. Sala £100 a year, with board, washing, and residence.

Guy's Hospital.—Demonstrator of Bacteriology and Bacteriologi Salary about £180, rising to £200 per annum.

Hospital for Consumption and Diseases of the Chest, Brompto —Resident House Physicians for six months. Honorarium £25.

Leeds General Infirmary.—Honorary Dental Surgeon.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 p annum, with board, apartments, and washing.

Lincoln Hospital for the Insane, The Lawn.—Assistant Medic Officer. Salary £100 a year.

Liverpool Royal Southern Hospital.—Junior House Surgeo Salary 60 guineas per annum.

Norfolk and Norwich Hospital.—House Surgeon, unmarrie Salary £80 per annum, with board, lodging, and washing.

North-Eastern Hospital for Children, Hackney-road, N.E.—Hou Physician for six months. Salary at rate of £80 per annum, wi board, residence, and laundry.

Northumberland House, Finsbury-park, N.—Assistant Medic Officer. Salary £120 per annum, with board, &c.

Nottingham General Dispensary.—Assistant Resident Surgeon, u married. Salary £160 per annum, increasing by £10 every yea with apartments, attendance, light, and fuel.

Oldham Infirmary.—Senior House Surgeon. Salary £100 per annu with board, residence, and washing.

Paddington Infirmary.—Clinical Assistant and Second Assista to the Medical Superintendent, unmarried, for six months. Hon rarium £36, with board, lodging, and washing.

Parish of St. Pancras, London.—Senior Assistant Medical Offic (Resident). Salary £135 per annum, with allowances.

Royal South Hants and Southampton Hospital.—Assista Physician.

Royal University of Ireland.—Examiners in Surgery, salary £5 Midwifery, salary £35; Pathology, salary £25; and Ophth mology, salary £20; in each case with travelling allowances.

St. Pancras and Northern Dispensary, 126, Euston-road.—Honora Surgeon.

Sheffield University College.—Demonstrator in Bacteriologic Laboratory. Salary £150, rising to £200 per annum.

South Lambeth, Stockwell, and North Brixton Dispensar Albert-square, Clapham-road.—Vacancy in Visiting Medical Staff.

Tottenham Hospital.—House Surgeon. Salary £50 per annum, wi board, residence, and laundry.

Tunbridge Wells General Hospital.—House Surgeon, unmarrie Salary £100 per annum, with board, apartments, gas, firing, a attendance.

Victoria Hospital, Folkestone.—House Surgeon. Salary £100 p annum, with board, residence, and laundry.

# Births, Marriages, and Deaths.

## BIRTHS.

Chambers.—On March 19th, at The Priory, Roehampton, the wife James Chambers, M.D. R.U.I., of a son.

Evans.—On March 23rd, at Upper Wimpole-street, the wife Willmott Evans, M.D., F.R.C.S., of a son.

Fawssett.—On March 16th, at Stratford-road, Sparkbrook, Birmir ham, Ethel, wife of Basil Fawssett, M.R.C.S., L.R.C.P. Lond., of son.

Hunnard.—On March 18th, at Mansfield, Notts, the wife of Arth Hunnard, M.B., B.S. Lond., prematurely, of a daughter.

Pearson.—On March 18th, at Aliceedale, South Africa, the wife Maurice Grey Pearson, M.B. Lond., of a son.

## DEATHS.

Caddy.—John Turner Caddy, M.D., died on March 21st at Chart house, Lion Gate-gardens, Richmond, Surrey, aged 80.

Phillips.—On March 19th, at Porchester-square, Francis Addis Phillips, M.R.C.S., L.R.C.P. Lond., aged 30.

*N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.*

# Notes, Short Comments, and Answers to Correspondents.

## SCOTTISH POOR-LAW MEDICAL OFFICERS.

our readers will turn to THE LANCET of March 8th, 1902, page 685, they will find an annotation under the above heading giving particulars of the differences between Dr. G. Nicoll, the medical officer of the parish of Clyne, Sutherland, and some of the ratepayers. Since then another meeting of ratepayers has been held at Brora on Feb. 28th in consequence of the Parish Council of Clyne not having acted upon the resolution of the ratepayers' meeting held on Feb. 11th demanding the dismissal of Dr. Nicoll. Mr. Andrew Ross, a ratepayer and a member of the county council, was elected chairman. The reply from the clerk of the parish council addressed to this gentleman and dated Feb. 13th was read. It acknowledged the resolution passed on Feb. 11th and stated that he had written to the chairman of the parish council (Mr. Sharp) for instructions. The chairman of the meeting said that he had heard nothing from that gentleman and thus they had met again. Four motions were then put to the meeting and carried *nem. con.* The first resolution was to the effect that the ratepayers' meeting was dissatisfied with the parish council in its still retaining the services of Dr. Nicoll, and dissatisfied with the chairman, Mr. Spark, for his lack of immediate action. The second resolution appointed a deputation of 12 ratepayers to wait upon the chairman of the council to learn his proposed action and requesting him to call an early special meeting of the council. The third resolution determined that should the parish council not take immediate action the matter be brought before the Local Government Board and the Medical Board. The fourth embodied the finding of the meeting that the officer should be dismissed instantly with payment of three months' salary in advance. Several councillors spoke at the meeting and it appeared that six months ago a motion was brought forward in the council to dismiss Dr. Nicoll; that five voted for it and five against; and that the chairman gave his casting vote in favour of keeping him. It is hardly necessary to add that the most prominent speakers at the ratepayers' meeting were some of the five who voted against the motion in council. This seems to have been the *primum mobile* of the matter. The chairman stated that the result of the deputation would be communicated to the ratepayers at a subsequent meeting. A deputation was then appointed which met the chairman of the parish council on March 3rd. He is reported to have replied that as the letter accompanying the resolutions was addressed to the council as a body he declined to take any action.

An interesting correspondance has been running in the pages of the *Northern Times* on this subject. One of the malcontents states that the parochial board of 12 years ago took steps to have a medical officer for its own parish and paid him £47 beyond the regular salary for attending paupers so that it could have a medical man nearer and at a cheaper rate to attend the other parishioners. "Lex Terræ," in reply, says he does not believe that the statement is correct; he states that such an arrangement is illegal and refers to the thirty-first annual report (1876) of the Board of Supervision whose decision in a similar case was that it was illegal to expend the funds raised for the relief of the poor in order to provide cheaper or more convenient medical attendance for persons who are not paupers. He refers also to the second annual report of the Local Government Board (1896), where it is pointed out that the inhabitants of a parish might make such arrangements as they saw fit to induce a medical man to settle in the parish, but these conditions could not enter into the contract between the parish council and its medical officer.

It seems to us that after being so narrowly defeated at the council meeting the minority have raised an agitation amongst the ratepayers starting with the assumption that their medical man is a sort of club doctor to the parish whom they have forced to accept a composition of a part of his proper fees, and in consequence that he is, like the parochial fireman, always at the beck and call, *nolens volens*, of any parishioner, especially an obtrusive ratepayer.

## GREEK FOUNDLING CHILDREN IN CONSTANTINOPLE.

THE LANCET of April 6th, 1901, p. 1020, we reviewed a work by Dr. Spiridion C. Zavitziano of Constantinople, in which that gentleman gave a very favourable account of the methods adopted by the Greek community in Pera for the rescue of foundlings, a system which has been in operation for about 12 years. Two or three months ago the Œcumenical Patriarch appointed a commission to consider whether the same system of caring for foundlings could be extended to the other suburbs of the Turkish capital, and this commission recommended the establishment of a maternity hospital with a view to the discouragement of abortion and infanticide. A serious difficulty has, however, now arisen because since the report of the commission has been printed the Turkish Government has issued an order to the police by which all the foundlings of Constantinople, whether they are of the Christian religion or not, must be sent to the poor asylum where, up to this date, the results have not been at all encouraging. For instance, out of 112 children admitted there only eight are now alive, whereas among the foundlings of Pera taken care of by the Greek community the death-rate is only 4 per cent. or less. Among about 80 of these last-mentioned children only two died during the month of January and none during the month of February. Under these circumstances it seems to be hardly possible to justify the new regulation made by the Turkish Government.

## FLUORIDES IN MEDICINE.

*To the Editors of* THE LANCET.

SIRS,—I shall be very much obliged if any of your readers can give me any information in connexion with the medicinal or other use of hydrofluoric acid and its compounds, and as to any injurious effects which may have resulted from their administration. I find that there is an increasing tendency to use them as food preservatives. I have noted references with regard to their use in Martindale and Westcott's Extra Pharmacopœia, ninth edition.

I am, Sirs, yours faithfully,  
March 18th, 1902. A. E. P.

## MR. RAWKINS REDIVIVUS.

AT the Plymouth County Court on March 12th Mr. William O. T. Annesley, L.S.A. Lond., brought an action against Mr. H. O. Lambart, L.R.C.P., L.R.C.S. Edin., for £5, balance of fees for acting as locum-tenent in April, May, and June, 1900, during which time plaintiff took charge of defendant's surgery at a salary of £2 2*s.* a week. Letters were read in court from defendant stating, "The surgery to pay expenses must make at least £4 per week, so charge them more and put in second bottles and plasters, ointments and lotions whenever you get the chance." "I saw you had given a six-ounce bottle to a child five years old, and the dose marked on it was one teaspoonful three times a day. Now you will see we shall never make a fortune at that rate. ...... Kindly remedy this. Give to a child of that age a one and a-half ounce bottle, charge 1*s.*, and order a teaspoonful every two or three hours, so that they may come back next day." The defence was that plaintiff did not perform his duties satisfactorily. His Honour Judge Lush Wilson, K.C., gave judgment for plaintiff for £2 18*s.* 11*d.* and costs.

Does anyone, we wonder, ever read nowadays a novel by Albert Smith called "*The Adventures of Mr. Ledbury*"? If so, he will remember the scene when Johnson announced that Mrs. Stokes wanted four more draughts and would call for them by-and-by.

> "Very good!" replied Mr. Rawkins. "Suppose you make it six. The bread bill will be heavy this week, and I shall want some ground bait on Friday. The extra three shillings will cover it."
>
> "Bob," shouted Mr. Prodgers ...... "Where are the clean phials?"
>
> "There ain't none," answered Bob. "I hadn't time to shot 'em."
>
> "We can send a mixture instead," said Johnson. "I can wash out this Reading-Sauce bottle in a minute."
>
> "No, no, by no means," returned Rawkins, "don't put her up to it. The minute people find that a three-shilling mixture holds more than four eighteen-penny phials, they put the skid on the draughts; wait for the little bottles."

So does history repeat itself, but it is the kind of history which needs no repetition. Mr. Lambart's situation was made to wear as undignified an appearance as possible, but he has his own letters to thank for this. It is an unfortunate fact that the medical man can always obtain thanks and sometimes payment for medicine, while his undiluted advice is very generally rewarded by neither. This attitude of the public, which is tantamount to a demand for a constant supply of drugs, compels medical men occasionally to order medicine so as to ensure their instructions being followed. It may also be here and there responsible for a revival of the policy of Mr. Rawkins, but we repudiate utterly any suggestion that such unworthy tactics are often resorted to by members of our great and philanthropic profession.

## STERILISED DRESSINGS IN PACKETS.

Messrs. Maw, Son, and Thompson have sent us a specimen packet of sterilised dressings. The specimen submitted to us contains Lister's cyanide wool. It is carefully packed in three papers, the outer being merely a covering layer. Within this is a layer of parchment paper carefully sealed with paraffin wax, and within this again another layer of thin paper. It is stated that the wool and the two inner coverings are carefully sterilised before putting up, and it is evident that the strict observance of all precautions will enable the surgeon to carry with him enough dressing for one case or so in a handy form.

## RARE MEDICAL LITERATURE.

Two rare old quasi-medical works were included in the sale of Lord Mexborough's library at Sotheby's auction-rooms, Wellington-street, W.C., recently. The first consisted of eight leaves, printed in a bold Gothic letter, 24 letters to a full page, and believed to have been issued by W. de Machlinia, of London, in the year 1483. The title runs, "Here begynneth a litill boke necessarye and behoveful ayenst the Pestilence," and the introduction states, "I the Bisshop (Ramicus) of Arusiens in the royame of Denmarke, doctour of Phisike, will write by the moost experte and famous doctours auctorised in Phisike somme thinges of the infirmyte of pestilence which dayly enfecteth and sone suffreth us to departe oute of this lyfe." This was sold for £160, the purchaser being Mr. Quaritch. The other work referred to was of the date 1652, the author being George Fidge, and the title "The Great Eater of Grayes-Inne, or the Life of Mr. Marriot the Cormorant, Wherein is set forth all the Exploits and Actions by him performed; with many pleasant Stories of his Travells into Kent and other places. Also a rare Physicall Dispensatory, being the manner how he makes his Cordiall Broaths, Pills, Purgations, Julips, and Vomits to keep his Body in temper and free from Surfeits." This realised £11 5s.

## A QUESTION OF FEES.

*To the Editors of* THE LANCET.

SIRS.—When attending a club patient with a dangerous aneurysm I at his request called in and conferred with my medical neighbours. Since the decease of the patient I find that the widow expects the club to pay the consultation fees, also my fee for meeting them in consultation. I have always made a rule of charging club patients a fee when I meet any medical man in consultation, and I think I am within my rights in so doing. Will you kindly express your view on the matter

I am, Sirs, yours faithfully,
March 25th, 1902. CONSTANT READER.

*** We think that such extra services rendered by the club medical officer as attending at a consultation *should be paid by the patient* or his representatives and not by the club. The patient or his representatives should also pay the consultation fees of the medical gentlemen called in to consider the case with the club medical officer.—ED. L.

## WANTED—A HOME.

*To the Editors of* THE LANCET.

SIRS,—Can any reader kindly recommend a comfortable home, in London or suburbs, where a lady, aged 76 years, would be well cared for? She is bedridden from right hemiplegia with contractures (no aphasia), and cannot pay more than £2 a week.

I am, Sirs, yours faithfully,
Teignmouth, Devon. F. CECIL H. PIGGOTT, M.D. Cantab.

## A WARNING.

*To the Editors of* THE LANCET.

SIRS,—A canvasser for a trade directory is calling at the houses of medical men at an hour when they are probably out and interviews their wives or housekeepers. He represents that the name of the medical man was in the last edition of his trade directory and asks sometimes 2s., sometimes 3s., for a re-insertion. His manner is plausible and he generally gets the money.—I am, Sirs, yours faithfully,

Romford-road, Forest Gate, March 21st, 1902. STEPHEN SMITH.

## COUNTRY HOUSE SEWAGE DISPOSAL.

*To the Editors of* THE LANCET.

SIRS,—I should be obliged if any of your readers would tell me the best way of dealing with the sewage of a country house having about one acre of ground. At present the sewage is conveyed into an underground covered tank made of unmortared walls, so that the liquid drains into the surrounding gravelly soil, the surface being thickly planted with trees. In wet weather the overflow comes to the surface and is at times offensive. The present system has been in operation or 12 years without causing any trouble, but now the soil is becoming "sick" and is a nuisance. The house is built on the slope and the soil is stony and porous. I am, Sirs, yours faithfully,

March 22nd, 1902. M.D.

## A CAUTION WITH RESPECT TO SAMPLES.

*To the Editors of* THE LANCET.

SIRS,—A tin box containing Bipalatinoids No. 581, forwarded by Messrs. Oppenheimer, Son, and Co., Limited, was incautiously opened and one of the bipalatinoids fell on the floor. My favourite cat played with it and ate it. In about half an hour after it was reported in a fit and when I saw it it was dead. It had micturated and its limbs were contracted. I referred to the prescription on the box and found inscribed —Ferrous carbonate (pil. Blaud), aloin, strychnia, ac arseniosi, āā gr. $\frac{1}{20}$, pulv. capsici, gr. $\frac{1}{4}$. Dose, one after meals. Strychnia gr. $\frac{1}{20}$ was the amount taken by the cat which caused its death by poisoning. If animals are about one should not be satisfied until such samples are burnt in the fire, as no other disposal is safe. I hope this may be a warning to others. I am, Sirs, yours faithfully,

F. A. PURCELL, M.D. R.U.I.
Manchester-square, W., March 24th, 1902.

## HOW DISEASE IS SPREAD.

TWO persons were fined 40s. each at the Glasgow Sheriff Court on March 20th for concealing cases of small-pox which had occurred in their respective houses. In the first case the defendant pleaded that the patient refused to see a medical man because he feared being sent to a hospital. The case was not discovered until after the patient's death. In the second case an Irishman was the accused. The first intimation which the sanitary authorities received was through the police who had been informed by neighbours. When
the medical officer called and asked to see the patient who was s
to be suffering from small-pox he was shown an elder sister and w
told that she was the only girl in the house. On going into t
kitchen, however, he found a young girl lying in bed, hidden
bedclothes, who was suffering from small-pox. The school boa
officer had been told that the girl was staying with some friends
Ireland. The elder sister was the only member of the household w
had been revaccinated and she was nursing the patient notwit
standing the fact that she was employed at home by a firm
dressmakers in the city. In reporting these cases the *Belfast W*
states that the sheriff regretted exceedingly that legislation o
provided a fine of 40s. for so gross a crime against the pu
interest. In the second case no comment seems to have b
made and no doubt the sheriff felt the impossibility of doing so
temperate language. In both instances the house was occupied
several people. We share the sheriff's regret that the fine which
Legislature has thought sufficient in these cases is so ridiculou
inadequate and we have called attention to the matter on sev
occasions, but until the law is altered and the penalty is m
greater the public will still be exposed to the danger of infec
through the criminal action of selfish or ignorant people.

THE writer of an account of a Case of Eclampsia, the manuscript
which bears no title or author's name, is requested to communi
with us.

THE writer of *a letter signed "G.P." and dated Feb. 17th is also*
quested to communicate with us.

◆

*Neurin.*—Our correspondent is recommended to apply to Profe
Adamkiewicz himself. His address is IV Wiedner Hauptstrasse
Vienna, Austria.

*J. B.* should consult his medical man. We do not give medical adv

## EDITORIAL NOTICES.

t is most important that communications relating to the torial business of THE LANCET should be addressed *usively* "TO THE EDITORS," and not in any case to any tleman who may be supposed to be connected with the orial staff. It is urgently necessary that attention be n to this notice.

*is especially requested that early intelligence of local events aving a medical interest, or which it is desirable to bring nder the notice of the profession, may be sent direct to his Office.*

*tures, original articles, and reports should be written on ne side of the paper only,* AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTI-FICATION.

*ters, whether intended for insertion or for private informa-ion, must be authenticated by the names and addresses of their writers—not necessarily for publication.*

*cannot prescribe or recommend practitioners.*

*al papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*ters relating to the publication, sale, and advertising departments of* THE LANCET *should be addressed "To the Manager."*

*cannot undertake to return MSS. not used.*

## MANAGER'S NOTICES.

### THE INDEX TO THE LANCET.

E Index to Vol. II. of 1901, which was completed with issue of Dec. 28th, and the Title-page to the Volume, given in THE LANCET of Jan 4th.

### VOLUMES AND CASES.

OLUMES for the second half of the year 1901 are now ly. Bound in cloth, gilt lettered, price 18*s.*, carriage

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

### TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to *the Agent to whom the subscription is paid and not to* THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

| FOR THE UNITED KINGDOM. | | TO THE COLONIES AND ABROAD. | |
|---|---|---|---|
| One Year ... ... ... | £1 12 6 | One Year ... ... ... | £1 14 8 |
| Six Months ... ... | 0 16 3 | Six Months ... ... | 0 17 4 |
| Three Months ... ... | 0 8 2 | Three Months ... ... | 0 8 8 |

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.
